The operation I have just described, gentlemen, I certainly consider the most satisfactory; it is a middle course between the Scylla of linearity and the Charybdis of flap extraction, and minimises the danger of each whilst claiming most of their advantages. I am not quite certain that the linear knife is the best for making the corneal section, and I have had a small knife made upon the Wenzel type, but as yet have not had sufficient experience to speak of it confidently. It certainly obviates an accident which, though not of very frequent occurrence or of great import when it happens, is best avoided. I allude to the iris falling against the edge of the knife, and a small piece being cut off on making the section. I think, gentlemen, we have arrived at a period when we cannot expect much better results than those we get. The removal of a cataract must be attended with some risks and some dangers; success cannot always crown our efforts. If statistics are to be relied upon, some operators have reduced their failures to 2 and 3 per cent., or even lower. Though I think in good selected cases such an amount of success is attainable, I do not believe anyone, however dexterous, could obtain such results from a large number of average cases containing immature, hyper-mature, and complicated cases of cataract such as present themselves at every large clinic. I calculate that I cannot have performed much less than 1200 cases of cataract extraction during the last sixteen years in my private and public practice, and of these close upon 1000 will have been cases of senile cataract. If I were able to give them to you in a statistical form I fear I should only bore you, and, further, the time at my disposal and the lack of clinical assistance have prevented me keeping accurate records of them all. Statistics, it has often been said, are only of value to mislead those who consult them. They certainly are only of use to the person through whose hands the cases have passed, and who understands, if I may so put it, the delicacy of their compilation. One hundred cases of cataract in the practice of one person cannot be usefully compared with one hundred in the practice of another. The cases themselves may differ materially. One may select only mature and uncomplicated cases. The patients may be of a different class. A rural and an urban population bear operations very differently. Lastly, though not least, the means of treating patients after the operation may vary infinitely. In my earlier cases I laboured under great disadvantages. Our hospital was small, inconvenient, and destitute of the most ordinary sanitary conditions. The result was that a considerable number of my patients were virtually treated as out-patients. Nevertheless, most of them did extremely well, and the virtue of necessity taught me a lesson which I have subsequently applied with advantage, and that is that in ordinary weather cataract cases should not be too closely confined after the first few days. I think from what I have said you will gather that it is useless to compare statistics of different operators, or even one's own, at different periods. Statistics to be of value should enter into every detail, and should in fact be accompanied by a complete and minute history of each case. The impossibility of doing this without the assistance of a number of clinics is obvious to all, and even with their assistance they could only be partially kept. Many of the cases disappear in a mysterious manner long before they are healed, and though known to be doing well never come back even for suitable glasses. Generally the results of my cases as regards loss of sight or complete failure have been as follows:—In the earlier periods of my career I performed 400 cases of flap extraction, with an average failure of 10 per cent. But, as I before said, my earlier cases were performed under great difficulties. I have now a comfortable and well-appointed hospital both for my private and public patients, with all the latest improvements science can command. My losses when performing the Belgian operation amounted to 7 per cent.; these were chiefly from secondary complications; and my losses in the last 200 cases performed by the method last described, and which for the sake of distinction we may call the "modified flap" or "small flap," has been 5 per cent. Latterly, for my own purposes, I have begun to classify my cataract cases somewhat after the manner in which some insurance companies classify their lives—viz., first class, second class, and third class risks. The first class contains all the cases of mature cataract in healthy persons not over seventy years of age; they are the best selected cases, and in them there should not be a proportion of failures exceeding 2 per cent. The second class contains all cases of immature or hyper-mature cataract, and cases of persons over seventy in whom the iris is sluggish and there is evidence of regressive changes in other structures of the eye than the lens; such cases, though not always easy to describe, are familiar to the practised eye of an ophthalmologist. The third class would contain cases in which distinct complications exist—iritic adhesions, sub-inflammatory conditions of the conjunctiva, blepharitis with slight ectropion, myopia in high degrees, increased tension, and abnormal lowering of sight in proportion to the cataractous condition of the lens. The second class would not have a much larger percentage of total failures than the first class, but would contain a larger proportion of the partially successful cases. The third class would contain by far the larger proportion of total failures, and if an operator, however dexterous, frequently undertook these cases, it would soon increase his percentage of losses.

It is not only in operative measures, gentlemen, that the treatment of cataract has made advance. It was to be expected that the development of the antiseptic system should find some application in ophthalmic surgery, although for a long time it resisted its charms. Wounds of the globe and cornea have a very effective and natural air-tight dressing in the shape of the lids, which keeps the parts in apposition and to a certain extent places any wound in the position of a subcutaneous incision. They are removed in a great measure from the influences which produce traumatic infection, and they usually heal quickly and well; still, suppuration does sometimes happen, with effects that are peculiarly disastrous to the organ of vision, producing irremediable and rapid destruction. To guard against these untoward results some have advocated and practise the strictest antiseptic precautions, including the spray and the full development of Listerian dressings. The greater part, however, content themselves with a modified form of antisepticism, which is certainly attended with beneficial results. The irritability of the mucous membrane of the eye will not tolerate contact with some of the more powerful forms of antiseptics and germicides; but in boracid acid, salicylic acid, weak solutions of corrosive sublimate, and iodoform we have substances which will fulfil all the indications we require. The details, as I carry them out, are as follows: On the morning previous to the operation the patient should twice have his eyes thoroughly bathed with a saturated solution of boracic acid made with boiling water, and slightly coloured with tincture of lavender; or a lotion containing two grains of corrosive sublimate to eight ounces of water. The lotion should have free access to the eye and permeate the inferior and superior cul-de-sac, its last application being immediately before the operation. After the operation the external parts are again cleansed with the same lotion and the closed lids covered with an oval-shaped piece of lint, well smeared with boracic vaseline of the strength of one drachm to one ounce. The hollow of the eye is then filled with cotton wadding and a knitted bandage applied over all. De Wecker, on the completion of the operation, rubs iodoform ointment over the corneal wound with a small spatula. I fancy this is an unnecessary complication; it might, to my mind, produce superficial irritation and hyperæmia, which would prove an initial step towards graver pathological changes. I need not say that the greatest care should be taken that the instruments are thoroughly cleansed, and those which I am about to use are always placed in a small vessel containing the same lotion that has been applied to the eye. These precautions, gentlemen, are certainly quite worthy your attention. They are simple and easy of execution, and they do not require a great deal of time or labour. But there are other points which we must not omit to mention. Persons who suffer from cataract have frequently other complications in the shape of slight congestive conjunctivitis, blepharitis, epiphora, obstruction of the nasal duct, and other things. All these are conditions which militate against a successful issue, and must receive careful attention and appropriate treatment. Do not allow yourselves to be led hurriedly into performing an operation in these cases until matters have been put into the best position possible. A few weeks' careful treatment and observation of such a patient will not be thrown away, and

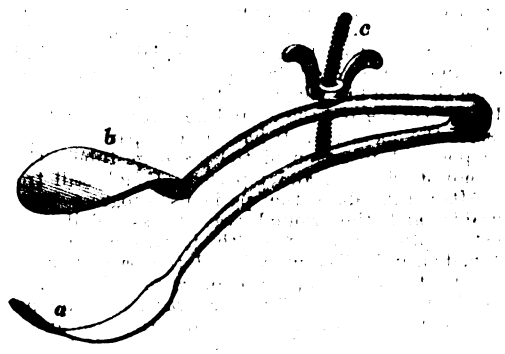
Digitized by Google

may convert what would have been a complete failure into a success.

One word on the question of anæsthesia, which time and space forbids my discussing more fully. The introduction of cocaine has practically removed cataract from the class of operations requiring general anæsthesia, and chloroform or ether should be reserved only for cases in which we are called upon to operate upon children or young persons who cannot exert any control over their nervousness, or for those special cases in which it is intended to remove the cataract in its capsule through a large section, or to accompany the operation by an iridectomy.

In conclusion, gentlemen, let me remind you that it is not always the surgeon who is the most brilliant and accomplished operator who can show the largest number of successes, but rather he who studies his cases, looks at them in every aspect, and exerts a personal supervision over every detail of the operation and the subsequent treatment, with a careful eye to eliminate all influences which may exert, directly or indirectly, a baneful effect upon the case. We cannot do better than bear in mind, with regard to the operation, the words which that accomplished writer and thinker Addison applied to life: "If you wish for success, make Perseverance your bosom friend, Experience your wise counsellor, Caution your elder brother, and Hope your guardian genius."

ON COMPRESSION OF THE INNOMINATE ARTERY.



WITH NOTES OF A CASE.[1]

BY THOMAS ANNANDALE, F.R.S.E.,
REGIUS PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF EDINBURGH.

IN this paper I propose to consider:—1. Temporary compression of the innominate artery in connexion with prevention of hæmorrhage in operations or injuries involving its main branches. 2. More permanent compression of this same artery in connexion with the treatment of aneurisms, involving its main branches.

1. It was my good fortune more than twenty years ago to assist the late Mr. Syme in many of his important operations upon aneurysms after the "old" method. In two of these cases the aneurysms involved the axillary artery, were of very large size, filled up the whole axilla, and projected under the clavicle, so as to make compression of the third part of the subclavian artery difficult and uncertain during the operation of laying open the sac. In one of these cases Mr. Syme made a small incision through the skin immediately above the clavicle and parallel to it, so as to allow the finger of an assistant to be passed into the wound, and so compress the subclavian artery more directly until the sac was opened, and the axillary artery secured at the point of communication with it. It occurred to me at the time of this operation that there was a certain amount of risk in opening into the aneurysmal sac or of rupturing it above the clavicle with the finger, an accident which would have much complicated the proceeding; and it further occurred to me that an axillary or subclavian aneurysm might so project into the neck as to make temporary compression of the subclavian artery between the heart and the aneurysm impossible. I accordingly made some dissections on the dead subject and some observations on the living body, and as a result of these I found that temporary and efficient compression of the innominate artery could be accomplished by a very simple proceeding. In order to assist in this compression I had constructed the instrument shown in the accompanying illustration. This instrument has now been in my collection for many years, but it was only quite recently I had an opportunity of using it in the case presently to be described. It consists of two blades (*a b*) united by a hinge joint and separated and approximated by means of a fine screw (*c*); its application will shortly be explained. I advocate the following method of compressing the innominate artery when the circulation in its chief branches cannot otherwise be controlled, as in the case of wounds or operations involving the right subclavian and first part of the right carotid artery. Make an incision in the middle line of the neck about two inches in length over the lower part of the cervical trachea, the same as is usually made for performing low tracheotomy; cut down through the various textures until the trachea is exposed, and it will then be found that the finger or a director can be insinuated by a careful separation of the tissues behind the innominate artery, and this vessel compressed against the sternum or sterno-clavicular articulation, so as to stay all circulation in its branches. This fact I demonstrated upon the living subject in the case appended to this paper. If preferred, the blade *a* of the compressor, protected by a piece of indiarubber tubing, can be gently passed behind the artery in the same way, the blade *b*, protected by an indiarubber pad, being placed outside over the upper part of the sternum. The instrument has been so curved that it lies across the neck obliquely without compressing the trachea. This instrument was also tested upon the case already referred to, and was found to be efficient. The special curve in the lower blade was found to be important in preventing the artery from slipping downwards over its point when compression was made. Although this case ended fatally, the temporary compression with the finger and instrument was not, in my opinion, the cause which led to fatal hæmorrhage, and it is important to note that no chest complication followed the proceeding.

2. Ligature of the innominate artery for the relief of aneurysm, involving the first portions of the right subclavian and right carotid arteries, has proved to be so fatal a proceeding that even with improved animal ligatures and antiseptic precautions surgeons hesitate to practise it. Neither has compression of the innominate artery in these cases given much encouragement. In the cases published

by Bickersteth[2] and Porter,[3] secondary hæmorrhage from the point of the artery compressed proved fatal. In both cases the compressor employed was applied direct to the walls of the artery, and was narrow in form. In Porter's case a kind of double aneurysm needle was used, and in Bickersteth's case wire connected with an ingenious arrangement of elastic bands formed the compressing agent. Having recently endeavoured to carry out compression of the innominate artery in a case of subclavian aneurysm by a method differing from those of Porter and Bickersteth, I record a note of it. I am especially wishful to report the case because the cause of the secondary hæmorrhage which killed the patient was unexpected, and requires careful consideration in connexion with the present and common use of indiarubber drainage-tubes. My proposed method of procedure in this case was: 1. To expose the innominate artery by means of the incision advised, with antiseptic precautions. 2. To insert one end of an indiarubber drainage-tube under the artery, and leave it there in position until the tissues had become accustomed to its presence, and until the risk of a septic condition of the wound was diminished. 3. When the latter conditions had been obtained, to introduce the small blade of the compressor into the drainage-tube, and carry on compression of the artery more or less continuously according to the effect produced.

J. B——, aged fifty-three, was admitted into the Royal Infirmary under my care on May 14th, 1885. His history was that in April, 1884, while lifting a heavy weight, he felt "something give way" at the root of his neck, and he became very faint and remained so all day. In the evening of the same day he noticed a swelling above his right

clavicle, which pulsated and slowly increased in size. On admission, an aneurysm of the third and involving a portion of the second part of the subclavian artery was diagnosed. He was treated by rest, careful diet, and the iodide of potassium for about a month, with the result that his symptoms were relieved, but the aneurysm remained in much the same state. He then left the hospital at his own desire, and he promised to return if he became worse. Nothing more was heard of him until he was readmitted in May, 1885. His symptoms had again increased, and he complained much of a dull aching pain over the right side of his chest, and shooting towards his back. The aneurysm was the size of a small orange, and pulsated strongly; a marked bruit was present. The tumour was situated immediately above the centre of the right clavicle, and the pulsation passed down into the axillary artery, which was somewhat dilated. The heart-sounds were normal, except that those over the aortic area were fainter than usual. The radial pulses showed signs of slight atheroma. The other internal organs were healthy. No history of syphilis could be obtained. On May 27th I exposed the innominate artery by the median cervical incision, and readily separated with my finger and a director the tissues, so as to allow the former to pass behind the artery and compress it against the sterno-clavicular articulation. The compressor was then applied, and found also to act in thoroughly staying all circulation in the vessel and its branches. The compressor having been removed, an indiarubber drainage-tube, with a diameter of half an inch, was inserted into the wound and adjusted so that its one extremity lay behind the artery and the other protruded from the external wound. The drainage-tube was secured in position by a piece of silk thread tied round the neck. The operation was performed with the usual antiseptic precautions, and the wound was dressed with salicylic wool applied loosely over it. On the 28th his temperature was 99·4°. The wound was dressed, and looked well. On the 29th he complained of pain in the wound, and had a slight dry cough. His temperature was 102°. On the 30th his cough was better, and his temperature was 101·2°. On the 31st the wound was dressed for the second time since the operation. It had in great part healed, except at the point of insertion of the drainage-tube. The tube was removed, cleaned, and replaced. Cough still troubled him. After this date the patient's progress was most favourable, and the wound was dressed daily; it remained aseptic. On June 6th it was noted that the cough had entirely disappeared and the patient was otherwise well. He still complained of some pain in the lower part of the neck. On the 7th there was a small quantity of blood upon the dressings, but nothing to cause any alarm. On the 8th, while the patient was sitting up in bed, serious arterial hæmmorrhage suddenly took place, which was temporarily checked by passing the finger deeply into the wound and compressing the artery against the sternum. Shortly afterwards I visited him, and finding that the bleeding proceeded from a point in the innominate artery, I prolonged the original incision along the line of the clavicle so as to expose the artery more thoroughly and apply a ligature round it. As I required to keep the finger of one hand upon the bleeding point, I found it impossible to pass a ligature round the vessel between the heart and this finger, although I made several attempts to do so. I then applied the compressor in the way described, and this completely stayed the bleeding. By this time the patient was almost pulseless, and, although no further bleeding took place, he sank and died about five hours after. The post-mortem examination disclosed an aneurysm about the size of a hen's egg involving a small portion of the second and the whole third portion of the subclavian artery. The axillary artery was also dilated, especially in the first part of its course. At a point on the posterior aspect of the innominate artery, and immediately below its bifurcation, there was an oblique slit or ulceration nearly a quarter of an inch in length involving its entire coats; the other portions of the artery and the heart and aorta were in good condition, and did not show any marked traces of atheroma. The ulceration in the coats of the artery exactly corresponded to the point against which the drainage-tube rested, and there were two small spots on the trachea which showed signs of commencing absorption, the result of the pressure of the same tube.

In connexion with this case I would remark, first, upon the cause of the fatal secondary hæmorrhage; and, secondly, upon the future prospects of compression of the innominate artery for the relief of aneurysms on the right side of the neck.

1. The cause of the fatal hæmorrhage was, in my opinion, the ulceration of the coats of the artery owing to the continuous pressure of the drainage-tube. I am not aware that the pressure of a drainage-tube has been thought likely to lead to so serious a result as in the present case, more particularly when the wound in which it lay remained aseptic; but from the experience of this case and of others of which I have quite recently heard, I consider that we must now reckon this risk as possible and avoid any lengthened continuous pressure upon a large bloodvessel by a drainage-tube. It may be said that the manipulation of the artery when the drainage-tube was first introduced may have assisted in destroying or weakening the coats of the artery, but as the artery was in a healthy condition and the manipulations of it were conducted with gentleness, I do not think so, and would attribute the rupture entirely to the results of the pressure of the drainage-tube.

2. Owing, then, to the unexpected accident caused by the drainage-tube, my proposed suggestions for the treatment of this case could not be carried out; nor do I advise that they should in any future case be employed exactly upon the same lines. I do, however, still hope that by some modification of the compression of the innominate we may succeed in relieving aneurysms which admit of no treatment other than the unsatisfactory one of ligaturing this artery. The direction of this modified compression should, I venture to assert, be on the principle of applying, with the assistance of a central cervical incision, digital or instrumental compression to the innominate artery, the patient being under the influence of some anæsthetic. Such compression should not be too continuous, and should be combined with distal ligature or compression, or, if thought advisable, with electrolysis.

THE EARLY TREATMENT OF RHEUMATOID ARTHRITIS.

BY JOHN KENT SPENDER, M.D. LOND.,
PHYSICIAN TO THE MINERAL WATER HOSPITAL, BATH.

(*Concluded from p. 441.*)

THE subject of Treatment is bright or dark according to circumstances—very bright if we have faith in our work, if the disease be in an early stage, and if we will take endless trouble to prevent a small spark from becoming an unmanageable flame. The therapeutics of rheumatoid arthritis is encouraging if we rightly estimate the proportion of general and local treatment, if the social and hygienic surroundings of a patient be favourable, and if we can secure the help of intelligent relatives and sensible nurses. When the nature of a case is clear, and the gravity of the coming evil plainly seen, it is downright treason to hide or to minimise it. Our duty is to be truthful, and at the same time it is a privilege to be hopeful; and in this spirit we shall best undertake what we are going to do.

Local treatment I put without hesitation in the foreground. By this is meant, not that in the long run the local treatment is the more important, but that we ought to begin with it, because time is urgent, and because in this manner we can make the earliest and deepest impression. Here is something wrong (call it what we will) in structures near the surface of the body; it is reasonable, it is almost certain, that we shall first influence this evil tendency by corrective discipline applied closely to the parts affected. It is easy to write with an air of learning about counter-irritation, although we know little about it as a theory; but there can be no doubt of its power as a piece of therapeutic work. Almost alone among recent writers has Dr. Mitchell Bruce advocated the necessity of vigorously striking home on the joints themselves.[1] It is satisfactory to quote a good authority in favour of a practice which I have followed for ten or twelve years. But the laws and limits of counter-irritation must be stringently observed. To put a cantharides blister all over a joint, or to paint the whole exterior of a joint with liniment of iodine, is to commit a grave therapeutic blunder. The antipathies of resentment are stirred in the vaso-motor apparatus under the skin, and the immediate

[1] Quain's Dictionary of Medicine. But it must be admitted that Dr. Bruce's opinions of the pathogeny of rheumatoid arthritis are contrary to established doctrine.

Digitized by Google

harm overshadows all possible future good. Mr. Furneaux Jordan's rule is plain and wholesome physiology. "Put your irritating agent," he says, "on the circumjacent skin, or, in other words, the neighbouring nerve and vascular territory." The artificial hyperæmia thus created draws away perverted force from the diseased area, and helps to restore an equilibrium. Paint a ring of linimentum iodi around the lower part of a thigh, two fingers' breadth away from a threatening 'rheumatoid' knee; let the ring be one inch and a half wide; renew it every two or three days, according to the coarseness or delicacy of the skin. Paint a similar ring below the knee, renewing it, not at the same time, but alternately with the ring above. If a cantharides blister be applied, let it be always on the cardiac side of a joint; and the blistered surface should be allowed to heal immediately. Another excellent method of counter-irritation is the frequent sponging of the affected joints in the earliest stage with water as hot as can be borne, the calorifacient edge of the heat being blunted by covering a joint with flannel or layers of muslin.

Many are the fine degrees and finer shades of what we call counter-irritation, and the method of using it should be always of the slow and quiet kind. Turpentine and its congeners are incendiary drugs, kindling a rapid fire which can be seldom kept within modest bounds. But there is a more generalised and tranquil method of so-called counter-irritation, which consists of immersing the whole body in hot or tepid water. The Bath thermal waters owe much of their repute to the well-attested faculty of alleviating the medical group of joint disorders, known as rheumatic, gouty, and osteo-arthritic. There is something in natural thermal water which confers upon it unique therapeutic power; for when stripped of the accessories of change of air and scene, of recreation and rest, a residual virtue is discovered which baffles the most searching inquisition. Thermal medicine is a matter of experience and tact; but this point stands out beyond all cavil, that the machinery of thermal bathing is successful in exact proportion to its early use. When proper means have been neglected at the proper time, then that stupid hope which leans upon anything will build castles in the air, and imagine a natural magic in ores, herbs, and waters. From this indolent delay there is often a cruel awakening. But if the regimen of a thermal spa be accepted and obeyed when a rheumatoid arthritis is in its dawn, if the twilight beginnings of a destructive disease are grappled with bit by bit, and hands are joined all round to beat back the foe, we may sometimes win the day when we least expect it, and add laurels to the honourable warfare of medical art.

Douching and shampooing are therapeutic kinsfolk to bathing, and (as a rule) all should go together. "Wet douching" is preferable when joints are sensitive and muscular action is attended by labour and pain. But for rousing structures out of drowsiness, and for stimulating them when afflicted with vital apathy, few agencies are so useful as "dry" hot and warm douches (the body being out of water). The thermal arrangements in Bath have been lately much improved; and a room has been attached to the "Queen's Baths," in which all the best appliances of Aix-les-Bains can be enjoyed, with foreign *doucheurs* and *doucheuses*. Shampooing is a technical mystery which cannot be too highly praised. The younger the patient who is menaced with rheumatoid arthritis, the more important does it seem to carry out stroking (*effleurage*) of the joints and tender kneading (*petrissage*) of the neighbouring muscles. The limbs should be always in the least constrained posture, and the application of bandages and laced supports will test the surgical instinct of the "wise physician." It cannot be said that the external use of drugs does any good; but I have been long accustomed to order the mild inunction every night of the iodide of potassium and soap liniment.

Climate is an element of soothing and healing value. To avoid the English winter and spring sounds disloyal; but to those who can afford it the sacrifice is imperative, and aliens they must be for six or seven months in the year. Between November and May residence should be taken up on the Mediterranean sea-coast, or part of the time may be spend in a sub-tropical sea voyage. This may need to be repeated every year for several years before complete success is obtained. Rheumatoid arthritis is a disease *par excellence* of the north temperate zone. But as the vast majority of people can only dream of the Mediterranean and the luxuries of Algiers and Egypt, they must learn to do the best for themselves in their own country, and to live in a dry and not too cold part of England; out of the "search of the glacier wind," says Mr. Ruskin, and as much as possible in the "rays of the rare sunshine." Internal medicines capable of doing good may be divided into two classes:—(*a*) Those of unquestioned efficacy, because of their obvious physiological appropriateness; and (*b*) those of secondary utility, but helpful according to their mode and measure of administration. In the front rank of the first class stands cod-liver oil, food and physic together; if begun in small quantities with pancreatine or orange wine, it may be pushed discreetly until half a pint is consumed every week. This must be continued for months, perhaps for years, omitting the middle of the summer; and it is a merciful plan to allow a holiday from all drugs once a fortnight. Citrate of iron (five or six grains) and iodide of sodium (two or three grains) may be dissolved and given together in chloroform-water once a day. Among our pharmaceutical resources of lesser importance are strychnia, arsenic, and syrup of the iodide of iron. When arsenic agrees, it may rise to the dignity of a valuable medicine, and there is no reason why it may not be given with the iron and cod-liver oil. Syrup of iodide of iron has been extolled by several writers, and is certainly a model of quiet harmlessness.

Countless hygienic rules may be laid down, and it will be a happy chance if our patient obeys half of them. Rooms well ventilated night and day; the steady morning and afternoon trudge out of doors, to keep muscles and joints from stagnation, and to promote the "metabolism" of effete stuff from the body; plenty of sun and sea; clothing adapted to the ever-shifting stress of weather; and meals of varied and well-cooked food. And if the mind and the affections be rightly guided what more can we do? In short, what we call the prophylaxis of cerebral and pulmonary consumption is the most rational way of warding off the diathetic state which leads to rheumatoid arthritis. The victories of preventive medicine have only begun to be unfolded.[2] When the hands and feet are the members first attacked, and the fingers are early disabled by pain and swelling in the smaller joints, the regular application of galvanic electricity may be tried. I cannot say much in its praise, and the therapeutic uncertainty of electricity has now become almost a proverb.[3]

From an abundance of clinical material I select a case which is interesting, because it shows what can be done when there is a determination all round to do the very best. In April, 1881, Sir Andrew Clark kindly entrusted to my care a young lady, aged seventeen, the daughter of a gentleman (a most munificent churchman) residing in the north of England. During 1879 she suffered much from chronic ulceration of the throat, and was obliged to leave school in March, 1880, "weak, white, and tired." The hands began to swell, and then the feet; many spas were visited during this summer for the benefit of her health; but in February, 1881 (after a severe winter), she became gradually worse, and pain and stiffness began to be felt in the left thigh and both shoulders. When she came to Bath she had great difficulty in raising herself from a chair, and walked with a stoop forwards; the muscles of the limbs were flabby from want of use; but there was no emaciation, and her manner and general tone were full of sprightliness and animation. The medical history of the family was good, with a marked exemption from rheumatic troubles. Many details are omitted for the sake of brevity; and it will suffice to say that a course of six weeks' thermal bathing here, followed by a similar period of perfect rest at Buxton, seemed to give the first impulse to that convalescence which was all the more firm and real because it was spread over several years. Every winter and early spring were spent at San Remo or at Cannes; sometimes there was a short visit to Aix-les-Bains; and four or five of the summer and autumn months were spent in England. Skillful shampooing was constantly used, and cod-liver oil was taken with as much regularity as possible. I heard from my patient once or twice every year; and in the last

[2] Horace tells Mæcenas that if he would live sound and in perfect health, the same indulgence which was granted to him when ill must be granted when he was afraid of being ill:—

"Si me vivere vis sanum rectèque valentem,
Quam mihi das ægro, dabis ægrotare timenti,
Mæcenas, veniam."—EPIST., lib. i., 7.

[3] In a paper read (June, 1880) to a Yorkshire branch of the British Medical Association by Dr. Little of Ben Rhydding, three cases are related of successful treatment by electricity, shampooing, and Russian baths. In the early stage of rheumatoid arthritis, however, Turkish baths and chamber vapour baths only weaken the patient without arresting the disease.

Digitized by Google

letter (from Cannes, dated Dec. 22nd, 1884) she says: "I have been so well this year. I am much stronger and better this year than last; I can walk much quicker, and have much more use of my hands. My weight also has largely increased." Now this patient might have been easily given up as hopeless; nor would there have been any ground for hope if she had been one of the crowd of those sufferers who are exposed to the chances of weather and poverty and mental depression. In these the little store of nerve force is exhausted by the physiological maintenance of common life. There is no reserve, no hidden power equal to the fervour and passion of driving out of the system a retrogressive change. There may be an amelioration of health, but the "supple government" of the joints can never be renewed.

In divers ways I have now endeavoured to show the "grief and gravity" of a terrible disease; to be a friendly monitor of its sure ending if unchecked, and to give a hopeful tone to our prognosis when opportune events put us in command of the whole line of treatment. In few diseases is time so irrevocable. Our pity should be aroused when beholding the monumental effigies of once bright and active men and women, now laid on sofas or Ilkley couches, and dependent for the humblest office on the ministry of others. The Laureate cheerily sings—

> "Oh! well for him whose will is strong,
> He suffers, but he will not suffer long."

But our dirge is of those who are doomed to suffer long, notwithstanding the comfort of a "strong will" and a supernatural grace. The corporate conscience of the whole profession ought to be stirred in this matter, for it is a reproach to medical art if any curable disease be let run into an incurable form. Dynamic disturbances, which may be easily plucked out in the early blossom, become anarchic and rebellious in their time of fruit. To wait for "specific" remedies or to trust to random discoveries is idle play and not scientific medicine. I venture to express the opinion that the proper treatment of rheumatoid arthritis consists in seizing the right threads at the very beginning, and in holding them with a fighting purpose to the very end. And it will be a natural conclusion to my argument if I suggest that the means be always precisely adapted to our aims, measuring the one with the other under the varying circumstances of race, sex, temperament, and age.

Bath.

SPASTIC PARALYSIS.[1]

BY A. HUGHES BENNETT, M.D., F.R.C.P.

MR. PRESIDENT,—At your invitation I attempt to bring before the Society a subject of great importance. It concerns a morbid state of widely-spread occurrence, and one which must therefore frequently come under the notice of every medical man. It is, notwithstanding, a condition very obscure in nature, causation, prognosis, and treatment. In consenting to open a conference on spastic paralysis, I do not anticipate that the darkness which surrounds the question will be illuminated by any original revelations of my own. I am, however, encouraged to venture the undertaking by the belief that directing attention to the leading problems to be solved will, without effort on my part, supply a text which the learned may expound, and thus initiate a discussion which may prove of scientific and practical value.

Spastic or spasmodic paralysis is the name which has been given by Professors Erb and Charcot, not to a disease, but to a group of symptoms—to a clinical picture—which must be familiar to everyone. It essentially consists of a morbid condition in which motor weakness, exaggeration of the tendon phenomena, and rigidity of muscles are the prominent and characteristic features. Owing to the existence of these physical states the patient afflicted suffers from certain symptoms which as a consequence ensue—namely, deficient voluntary activity, tremors, peculiarities in gait, and distortions of the limbs. This combination of circumstances is, moreover, not of necessity associated with any interference with the general health or the functions of the body, and the intellectual, sensory, and nutritive organs may be preserved intact. In short, this train of abnormal symptoms, to which the term "spastic" has been applied (owing to muscular spasm being the leading feature of the disorder), is strictly confined to the motor elements of the nervous system.

The *distribution* of this spastic condition varies. It may be confined to a single limb, it may assume a hemiplegic or a paraplegic form, or it may involve all four extremities and every district of the body. As regards *causation*, it may be associated with degeneration of the lateral columns of the cord, secondary to disease of the brain or pyramidal tract, as in cerebral hæmorrhage, myelitis, &c.; or the lesion may be of primary origin in the same regions, thus constituting a disease *per se*, as in so-called primary lateral sclerosis. Also it is met with as a functional disorder from unknown causes, as in hysteria; and it may be the result of certain definite blood-poisons, such as strychnia and lathyrus cicera. Further, as to *pathology*, it is frequently accompanied with demonstrable structural alteration in the nervous system, which appears to be its direct cause, and as often all traces of discoverable tissue change are absent. Again, the *progress* of the disorder is not uniform: at one time it invades rapidly, is acute, and of short duration; and at another is insidious in origin, chronic, and of long persistence. Finally, its *termination* varies, in some instances the disease being hopelessly and permanently incurable, while in others the patient rapidly and completely recovers. This varied distribution, origin, pathology, progress, and termination of the same group of symptoms furnishes a mystery to unravel, and serves to show how perplexing are the difficulties of the subject under notice.

Various theories have been propounded to explain the occurrence of spastic paralysis, the essential features of which, it may be repeated, are motor weakness, exaggeration of the tendon phenomena, and muscular rigidity. Professor Charcot maintains that the symptoms are due to irritation of the ganglion cells of the grey matter of the cord by degenerated contiguous fibres of the lateral columns. It is now well known that a destructive lesion of the motor cortical area in the cerebral hemispheres, or in any portion of the pyramidal tract, induces secondary degeneration of the efferent fibres below, which are thus cut off from the trophic influences of the cells in the grey matter of the brain. This sclerosis extends downwards as far as the multipolar ganglia in the anterior cornua of the cord, and the hypothesis suggested is that the morbid process on reaching the cells causes their irritation, and as a consequence the phenomena of spastic paralysis. That this theory is plausible cannot be denied, and it is possible that it may be a factor in the production of the clinical symptoms in question. It is at best, however, only an imperfect explanation, and not the essential cause, as spastic paralysis may exist in its most typical form when no degeneration of nerve fibres can be demonstrated, as in various functional complaints such as hysteria. Moreover, it may occur under circumstances where it is impossible to conceive the presence of any such permanent or gross structural alteration, as in strychnine poisoning or during the hypnotic state.

Another theory, and perhaps the most popular, asserts that the symptoms of spastic paralysis are due to the simple severance of the spinal from the cerebral centres. In this way it is supposed the inhibitory action of the higher is removed from the lower ganglia. These last are, as it were, thus permitted, from want of control, to run riot, and as a consequence to manifest hyper-excitability of reflex acts, in the shape of increased tendon phenomena and muscular rigidity. It is admitted that during the absence of brain influences the reflex excitability of the cord is augmented, but the train of symptoms included under the term spastic are not produced. Moreover, in sudden destructive lesions of the brain, such as hæmorrhage into the pyramidal tract, although spastic symptoms subsequently ensue, they do not appear until a considerable period of time has elapsed. Now, if simple inhibition were the sole cause of the phenomena, we should expect the effects to be most marked at the moment of interruption, and not gradually acquired, as is the case.

A third theory, which is a modification of the last, maintains that when cerebral influences are suppressed the uncontrolled action of the cerebellum as a stimulator of muscular tonus becomes prominent, and hence the stiffness which takes place. The same arguments which can be

[1] An introduction to a discussion on the subject at the Medical Society of London, March 1st, 1886.

Digitized by Google

urged against the last hypothesis seem to me to equally hold good against this. A further proof of its inability to account for the position is, that when the cord is completely divided, as in transverse myelitis, spastic symptoms subsequently ensue, although all communication between the cerebellum and cord has been severed.

Such are the leading theories which have been advanced to explain the phenomena of spastic paralysis, as well as some of the reasons to show that no one of them by itself is adequate to account for their production. While it is not difficult thus to take a negative view of the position and criticise existing doctrines, it is not so easy to successfully assume a positive and constructive attitude, and to replace received opinions by others more worthy of acceptance. In attempting to frame a hypothesis which will harmonise with all the facts of the case, it seems to me that the entire question must be viewed from a more comprehensive standpoint than heretofore. The present tendency of neurological science is towards specialisation, and doubtless the great advances it has made of late years is mainly due to success in that direction. At the same time, in order that the accumulation of isolated facts may be utilised to the fullest extent, the laborious process of individual inquiry must be supplemented by generalisation. In the disorder under consideration, as well as in many other morbid states, by taking a more extended view of the situation, it may be found that the supposed classical lesion of a disease is only one factor in its etiology; that, indeed, it may be a result rather than a cause, and that a variety of circumstances from different directions may all equally tend to produce the same effects. Looking, then, at the clinical picture of spastic paralysis, as it were, from a distance, and taking into consideration the manifold conditions of its causation, progress, and morbid anatomy, the following conclusions seem to me to be those which best accord with known facts.

From whatever source the disorder may arise, the symptoms are essentially the same, varying only in distribution and degree. The characteristic motor weakness, the exaggerated tendon reflexes, and the muscular rigidity belong to the same series of phenomena, and have the same physiological signification. The common factor in the production of this series of conditions is an abnormally increased irritability of the motor ganglion cells in the anterior cornua of the cord. Physiological knowledge has taught us that one of the functions of these centres is to maintain a certain degree of permanent tonus of muscular fibre. For this purpose integrity of the reflex arc is necessary. Hence if either the ganglion itself, or its afferent or efferent elements are destroyed, the muscle relaxes, and its response to mechanical percussion (in other words, its tendon phenomenon) is lost. If, on the other hand, the ganglion is from any cause in a state of hyper-excitability, the opposite conditions ensue—namely, hyper-tonicity or rigidity of muscle and spastic symptoms. The order and extent in which the different symptoms appear to develop seem to bear some relation to the amount of excitability of the cells; hence the first manifestation of their irritable weakness is motor paresis, and then in order appear, according to its degree of severity, increased tendon reflexes, clonic spasms, muscular rigidity, and permanent contracture.

If, then, a morbid irritability of motor ganglia is the common property of all forms of spastic paralysis, we have next to determine how this in turn is produced. I believe that this is not to be found in any single explanation, but that a variety of circumstances may act as exciting agents. These circumstances may be mainly divided into three categories: (1) Primary irritation of the ganglion cells themselves; (2) their irritation through the afferent and efferent paths from below; and (3) their irritation through the pyramidal tract from above.

The ganglion cells may be primarily affected in many ways. Strychnia and other poisons, for example, may directly derange their nutrition and produce temporary spastic symptoms. Changes in the quality of the blood, such as anæmia, fevers, &c., may in a lesser degree be followed by the same results, and it is common in such circumstances to meet with muscular weakness, increased tendon phenomena, and a tendency to cramp and stiffness of muscle. The same irritable weakness is found in most exhausting ailments, such as phthisis and convalescence from acute diseases, in which the grey matter of the cord participates with the other tissues of the body in an abnormal readiness to respond on stimulation. It is still further developed in those states of nervous instability characterised as neurotic, such as hysteria, in which spastic symptoms often reach a very high degree.

In addition to direct irritation of the ganglion cells themselves, these elements may be influenced by irritation from below. The well-known observations of Brown-Séquard demonstrated that injury to afferent fibres may cause so-called spinal epilepsy—in other words, extreme hyper-excitability of the grey matter of the cord. Again, Dr. Weir Mitchell, and my colleague, Dr. Donkin, have advanced clinical reasons to show that over-stimulation of the efferent tracts may produce the same results. Such evidence tends to indicate that peripheral irritation of both afferent and efferent fibres may alike lead to hyper-activity of the ganglia to which they are attached.

Influences from above may in like manner be followed by similar results. Experimental irritation of the motor cortical area induces muscular spasm. In disease the same occurs. It has been observed that during an epileptiform attack—that is, during a period of cortical irritation—there is both contraction of muscle and exaggeration of the tendon phenomena, showing that the excitement of nerve tissue has extended to the cord. Even after voluntary motion has been abolished, owing to the temporary exhaustion which follows an explosion of the cortical motor centres, the exalted functional activity of the lower ganglia may remain, and consequently the spastic symptoms may continue. In a short time, however, when the secondary irritation of the cord subsides, the symptoms disappear. In like manner, irritation from inflammation or otherwise in any portion of the pyramidal tract may be followed by similar results, and if the cause be chronic the symptoms may be permanent.

Again, it has been found that not only an irritative lesion, but destruction of the cortical motor area subsequently, but not immediately, leads to muscular hyper-tonicity. The same takes place from disease of any part of the pyramidal tract by which the distal portion is separated from the cerebral trophic elements. This may possibly be due to direct irritation caused by the secondary descending sclerosis, as suggested by Charcot. But prior to demonstrable degenerative change in the lateral columns there are evidences of motor instability, as a few hours after an apoplexy exaggerated tendon phenomena gradually develop. It is therefore obvious that nutrition changes, as a result of removal of cerebral trophic influences, must exist in the motor tract before structural alteration can be apppreciated. The nature of this change, whether vascular, molecular, or dynamic, we do not know, but that it is sufficient to produce objective functional symptomatic disorder is certain. A plausible explanation of this fact would be that anæmia or other nutritive modification of the pyramidal tract was the almost immediate consequence of the disorganised trophic centres above, and that this change in the circulation or molecular stability led to irritable weakness of the adjacent grey matter of the cord. The same effects might supervene upon conditions other than those of actual gross cortical disease, as when the higher nervous elements, without demonstrable anatomical change, are functionally disordered. In such a case the actions of the parts below which are dependent for their constancy on healthy influences from above, would be deranged. Thus from functional irritability or depression of the cerebral cortex there might arise instability of the pyramidal tracts and the motor apparatus connected with them, and, as a consequence, a train of typical spastic symptoms. Such excitants would be all the more potent in a predisposed subject in whom the spinal ganglion cells were already in an abnormally exalted condition, as in such the slightest physical injury readily provokes muscular spasm. Under the same or similar conditions it is but a step further to realise that psychical influences may act as exciting agents for the production of like results. Thus, misdirected volition, emotion, or imagination acting as afferent stimuli might be the originators of abnormal motor phenomena, even when the nervous system itself is in other respects healthy. Again, even normal mental impulses may cause undue motorial demonstrations if the spinal centres are hyper-excitable, as is seen in strychnine poisoning, hysteria, &c. It is therefore obvious that if both these abnormal conditions exist together—that is, increased power of the higher centres to receive or originate mental impressions, and augmented capacity of the lower centres to respond to psychical stimuli—the effects will be the more violent in degree and permanent in duration, and serves to explain the severity

Digitized by Google

and intractability of many functional disorders. It also gives an explanation of the fact that under these circumstances the physical motor symptoms are sometimes such as could not voluntarily be produced in health, as instanced by the phenomena of hypnotism and hysterical malingering.

In connexion with these reflexions it is a question of the greatest practical importance to know whether repeated and permanent functional over-activity or depression can lead to demonstrable structural changes in the tissues affected. *A priori* reasoning would favour such a hypothesis, although there is not a sufficient series of recorded facts to demonstrate it. At present brevity compels me to forego speculation on this interesting subject. Everything, however, seems to indicate that the causes which lead to hyper-excitability of the ganglion motor cells, and consequently to the production of spastic paralysis, are of an active or irritating rather than of a passive or inhibitory nature. This is supported by many facts; among others, that when one side of the body is primarily affected, there is invariably a tendency for the other gradually to become involved; also, that all circumstances which allay irritability, such as rest, sleep, tranquillity, and sedatives, relieve the symptoms, while the reverse conditions of emotion, exertion, injury, and stimulants augment them.

To sum up, it is suggested that spastic symptoms, from whatever cause arising, are essentially due to abnormal functional hyper-excitability of the motor ganglion cells of the anterior cornua of the cord. The hyper-excitability may for various reasons be inherent in the cells themselves, or may be induced therein by influences emanating from the brain, the cord, or the peripheral nerves. These influences are probably of an irritating nature. The irritation, when it exists in the pyramidal tract, may be excited there either directly by organic disease or functional excitement, or indirectly by changes in its nutrition as a result of severance from its trophic centres. These changes in nutrition may be either gross or dynamic. The gross changes usually follow gross disease of the cortical centres, while the dynamic changes may either follow their structural alterations or their functional disorder. Finally, this functional disorder of the motor tract may have its origin in psychical as well as in physical activity. These theoretical considerations concerning the pathology of spastic paralysis, like other hypotheses, are open to criticism. I admit they are somewhat involved, but this is scarcely to be avoided in attempting to account for the complicated circumstances connected with this group of symptoms.

If, gentlemen, the doctrinal speculations on the subject we are discussing are uncertain, the practical difficulties met with at the bedside are none the less perplexing. As their clinical features are now well recognised, I pass over those forms of spastic paralysis associated on the one hand with secondary changes from gross disease of the nerve centres, and on the other with obvious functional disorder. I limit myself to directing attention to a condition in connexion with this subject, which has always seemed to me most obscure, and which I cannot find anywhere accurately differentiated or satisfactorily explained. It is a group of symptoms which everyone must have met with, and of which there are in the other room several illustrative examples. In my own limited experience it is of frequent occurrence; and I find in my note-books of the last two or three years the detailed account of twenty-four typical examples. An individual, either male or female, in otherwise good health, without obvious cause, gradually experiences slight weakness in a limb—say, the leg. This, as a rule, very insidiously increases, and, after a year or more, extends to the arm of the same side, sometimes to the opposite leg, and subsequently to all the extremities. On examination motor weakness is detected without incoördination; there are clumsy and feeble actions of the upper, and a weak, shuffling, stiff, gait with the lower, extremities. At an early stage there is great exaggeration of the tendon phenomena, the cutaneous reflexes remaining normal. Afterwards ankle-clonus is developed, and later slight stiffness of the muscles and trepidation of the limbs. The general health remains robust, and all the organs and functions of the body are normal. Sensibility and nutrition continue unimpaired. Occasionally, but very rarely, in my experience this abnormal condition is acute, and reaches its full development with great rapidity. The affection may entirely recover, but as often it persists for many years without change, or slowly increases in severity. The disorder is one evidently limited to the motor apparatus. It imperfectly answers to the description of the "primary lateral sclerosis" of Erb and Charcot, but differs from that disease, inasmuch as it is of common occurrence, it frequently recovers, and also because spasm of muscle with its consequences is not the leading feature of the affection. It is a condition which, when occurring in women, is almost invariably pronounced to be hysterical; when in men, it is vaguely called paraplegia or myelitis. For convenience I describe the group of symptoms under the term "hyper-tonic paresis," a symptomatic nomenclature which commits to no theory. This in every respect answers to the hypothesis I have already advanced concerning the nature of spastic paralysis.

In conclusion, I venture to suggest the following points for discussion:—1. Is the organic degeneration of the lateral columns of the cord, so frequently associated with spastic symptoms, essential for their production; or may they be accounted for by functional derangement of the same regions, or of the psychical or motor centres? 2. Whether organic or functional, is the primary seat of disease in the cells of the brain or cord, or in the conducting fibres, central or peripheral? Are the symptoms the result of irritation or inhibition? 3. May primary functional disorder eventually lead to secondary organic degeneration? 4. Regarding the cases described under the term hyper-tonic paresis. What is the anatomical substratum of the affection? Where and in what manner does it originate? Is the condition one of organic or functional disease, and by what clinical criterion is the point to be determined during the life of the patient? What is the cause, prognosis, and treatment of the disorder?

A CASE OF RUPTURE OF THE KIDNEY.

By G. Y. EALES, M.R.C.S., L.R.C.P. EDIN.,
LATE ASSISTANT-SURGEON, SIRHOWY AND EBBW VALE IRON AND STEEL WORKS, MON.

THE following interesting case is, I think, on account of its comparative rarity worthy of record.

On April 10th, 1885, I was called to see S. G——, aged thirteen, a collier, who it was stated had been severely injured by a fall of coal while at work in one of the company's pits. I found him lying on his back with the shoulders raised up, thighs flexed (especially the right one), face pale and of anxious appearance, surface cold and bathed in sweat, pulse rapid and feeble, and respiration shallow and of intercostal type, there being but slight diaphragmatic movement. A deep breath caused intense pain in the right lumbar region. He had vomited several times, and was, in fact, in a state of collapse. On examination I found an extensive contusion in the right lumbar region, and slight abrasion of skin over the eleventh and twelfth ribs. The patient complained of such intense pain on pressure that I was unable to ascertain if any ribs were fractured. There was also a slight contusion on the right shoulder, another in the hypogastrium, and another on the posterior aspect of the right thigh. There was no tenderness on pressure in the hypogastrium. In the evening he passed a large quantity of bright arterial blood, mixed with urine, and vomited several times.

April 11th.—11.30 A.M.: Very weak and anæmic. Pulse hardly perceptible at the wrist. Had vomited constantly during the night, and had passed urine tinged with blood. Some fulness in the right iliac region, with dulness on percussion. Complained of great pain all over the right half of the abdomen, and tenderness on pressure.

12th.—Yesterday, about 9 P.M., he passed some urine slightly tinged with blood. To-day he has voided nothing from the bladder. There has been no vomiting. Complained of pain all over the abdomen. Thighs strongly flexed on abdomen, and abdominal walls rigid. Died in the night from a combination of anæmia and shock, having lived sixty hours since the accident.

Necropsy.—I made a post-mortem examination in conjunction with Dr. Coates (chief surgeon to the works) and Dr. Henderson (senior assistant-surgeon, Tredegar Iron Works). Body short for the age, and thin. The right side of the abdomen showed extensive bruising. On opening the abdomen we found a large quantity of blood in the peritoneal cavity. No injury to the diaphragm or liver and no fracture of any ribs could be detected. There was no

Digitized by Google

apparent injury to the intestines, but portions of the ileum in the neighbourhood of the kidney showed commencing peritonitis. The right kidney was displaced downwards and forwards, and lay in the iliac fossa; behind it was an enormous amount of blood-clots and effused blood, the latter extending along the cellular tissue almost to the middle line of the abdomen in front. There was also a quantity of blood-clots immediately in front of and on the right side of the lumbar vertebræ, overlying the solar plexus and semilunar ganglion; this had apparently spread along the renal plexus of vessels; it did not extend over to the left side of the vertebræ. The peritoneum anterior to the kidney was severely lacerated, and so allowed escape of blood into its cavity. The upper half of the kidney was literally smashed into a pulp, but more so on the anterior surface than the posterior, extending down to the pelvis of the kidney. There were several large branches of the renal artery laid open. We could detect no wound of the trunk artery or vein. There was also a small deep jagged wound in the lower half of the kidney on the posterior surface, which looked as if a rough object had been driven into it. The ureter appeared to be completely blocked by a blood-clot. Bladder empty and healthy; left kidney and ureter healthy. There was no evidence of the lower ribs having been driven through the abdominal walls.

Remarks.—The noteworthy feature of this case is how such an extensive injury to the kidney should have been caused without fracture of any ribs. The sudden cessation of hæmaturia was apparently due to clots in the ureter. The rapidly-increasing anæmia, together with the hæmaturia and fulness of the iliac region, pointed presumably to hæmorrhage from the kidney; accordingly, astringents were given. Mr. H. A. Reeves, F.R.C.S., in a case published by him in THE LANCET of Oct. 4th, 1884, says that as soon as it is found that hæmorrhage is not controllable after trial of every known means, a lumbar incision should be made over the kidney, and all clots and blood removed, and the kidney also, if necessary. It occurred to me, if it would have been justifiable to cut down and remove the kidney as soon as it became evident that hæmorrhage was profuse, obviously in such cases to wait the effect of a lengthy trial of astringents means waiting till too late. I do not feel competent to give an opinion as to the actual cause of this injury; but remembering the fact that the boy was crushed beneath a great mass of coal, it occurred to me that the kidney may have been suddenly dislocated, as it were, by the force of the blow, and at the same time caught between the vertebræ and the suddenly compressed ribs; and what makes this idea more tenable is the fact that the boy was small and very thin for his age, and that the anterior portion of the kidney was the most severely damaged.

Kettering.

ON A

FATAL CASE OF ACUTE DELIRIOUS MANIA COMPLICATED WITH PAROTITIS.

BY JAMES M. WILLIAMSON, M.D. EDIN.,

HONORARY SURGEON TO THE ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR, ETC.

THE patient in this case was an American lady, aged forty, but looking older. She was a highly educated and talented woman, and was the principal of a large educational establishment. Overwork had brought on nervous prostration and insomnia, for which Dr. Hammond, of New York, ordered rest from work and change of scene. For twelve months the patient followed this advice, travelling in England, but without much benefit. During April, 1885, while at Bournemouth, she had a throat attack, suspected to have been diphtheritic, and accompanied by what she called "delirium." The patient came to Ventnor early in the next month (May), and consulted me on the 10th for insomnia. Her catamenia, regular as yet, began on the 12th, and brought on increased restlessness and irritability, upon which chloral and the bromides made no impression. On the 14th she was in bed, her mind excited and wandering. The pulse was rapid, but the temperature not elevated. The tongue was dry; the breath offensive; appetite absent; but the bowels were not confined, and the urine was freely voided. In two days more she was deliriously insane, howling, laughing, incessantly talking, struggling, and trying to bite. She spat out food and saliva, and urine and fæces were passed into the bed, which had been made up on the floor. Morphia, given hypodermically, increased the excitement; but chloral—administered with much difficulty—somewhat lessened it. On the 21st she was seen with me by Dr. Blandford of London, who confirmed the diagnosis. As the heart had begun to intermit, the chloral was abandoned, and paraldehyde ordered instead. The food was limited to eggs and milk. From this time slight improvement took place until the 24th, when swelling of the left parotid gland was observed. The swelling had taken place rapidly during the night, and extended to the malar bone and behind the angle of the jaw; it was hard and very tender, but free from redness. Two days afterwards the right parotid took on the same action, giving the patient the characteristic aspect of mumps. During gleams of consciousness much complaint was made of pain, and attempts at swallowing were virtually abandoned. Feeding by the nares was impracticable, whilst hæmorrhoids that bled copiously at every touch precluded the use of nutrient enemata. No suppuration took place in the parotids, but from this time the strength swiftly declined. Exhaustion passed into coma, and death took place on the 29th, which was the sixteenth day of the illness.

Remarks.—It is to the occurrence of the parotitis in this case that attention is drawn, and it is worth noting because it really turned the balance against the patient at the critical point in her illness. Without referring to the difficulties it threw in the way of treatment, the question of causation is full of interest. It was clearly not a case of idiopathic parotitis. Anyone who had for the first time seen the patient when both parotids were swollen would assuredly have thought of mumps and meningitis; but even had there been no history the delirium could not have been mistaken for that of meningitis. The condition was symptomatic, and not idiopathic. A great deal is heard now of the sympathy between the parotids and affections of the generative organs; in this case, however, although the approaching menopause may have had some share in inducing the maniacal attack, so far as could be ascertained there was nothing wrong with the external or internal organs of generation, or with the mammæ. The case ranks with those similar affections of the parotid which have long been known to occur towards the termination of fevers. Some have held that in these circumstances the parotitis results from a spread of the specific poison of the fever. Since the condition has been seen in pneumonia, however, others have ascribed it to the extension of oral inflammation. The present instance confirms the latter view. The mucous membrane of the mouth was dry and parched and covered with dead epithelium; possibly the milk that was retained in the mouth helped to increase the oral inflammation; but no aphthæ were seen. The incessant action of the jaw and the retention of saliva in the parotid may have been contributing agents. So far as I can gather, this parotid complication, well-known in some severe diseases, does not appear to have been much recognised in connexion with acute delirious mania.

Ventnor, Isle of Wight.

ON SOME OF THE PROPOSED CHANGES IN THE LUNACY ACTS.

BY JAMES ADAM, M.D.,

RESIDENT PHYSICIAN, &C., WEST MALLING ASYLUM; LATE MEDICAL SUPERINTENDENT, CRICHTON ROYAL INSTITUTION, SOUTHERN COUNTIES ASYLUM, AND CATERHAM ASYLUM, SURREY.

THE measure introduced by Lord Selborne is already familiarly known to the public and the medical profession. It was presented to the House of Lords during the last session of the last Parliament, and was ordered to be printed on March 26th, 1885. It met with by no means unanimous approval, and some of its provisions were so much objected to that they led to the resignation of Lord Shaftesbury as chairman of the Board of Commissioners in Lunacy; but it was hailed with satisfaction by others, and it came at last to be accepted on the belief that it was necessary to do something to allay the public agitation and suspicion which had been strongly aroused on the subject. The Bill passed through

Digitized by Google

the House of Lords, and as amended in committee was ordered to be printed on May 30th, 1885; but, owing to the change of Government occurring about that time and the rapid winding up of the session, it became a dropped order, and did not reach the House of Commons.

The principal objects sought to be attained by this Bill may shortly be stated as follows:—To furnish safeguards against the improper confinement of persons as lunatics; to give facilities for the medical treatment of persons who desire to submit to treatment; and to enable public asylums to be provided for the reception of lunatics not paupers. It was stated that the Bill adopted in the main the recommendations made by the report of the Select Committee of the House of Commons on Lunacy Law in the year 1878, and that the principle of the Scotch procedure had been adopted. No part of the Bill was more warmly discussed than Section 3, which provided that, except in cases of urgency, a person not a pauper should not be confined as a lunatic without an order of a county court judge, stipendiary magistrate, or justice, to be obtained upon a petition presented, if possible, by a relative, and accompanied by two medical certificates; and it was the retention of this provision in the Bill after protest against it by Lord Shaftesbury which led to his resignation, as already stated. It is perhaps unnecessary to remark that it is on this point also the Scotch procedure differs most essentially from the English; and much has been urged both for and against its adoption in England. In Scotland, except in cases of emergency or voluntary submission to treatment, with the previous assent of the Board of Lunacy, no person of unsound mind can be legally received into an asylum for the insane without the warrant of a sheriff, who is the principal legal functionary in each district. The sheriff grants this warrant upon the petition of a relative of the patient or other person, accompanied by the certificates of any two legally qualified medical practitioners resident in Scotland; but it is distinctly and clearly understood, and even stated by sheriffs, that they look upon their functions in this respect as "purely ministerial"; they consider their duty simply to consist in examining the various documents put before them, and if they are found accurately filled in the warrant is granted without further question; the alleged lunatic is neither seen nor examined by the sheriff personally, or those acting under him.

Now, it may be asked, where is the actual and real safeguard to the liberty of the subject here which does not already exist in the English Acts? In each country there is the same intervention of a relative or other person and of two medical practitioners. In England the "ministerial" act of the sheriff alone is wanting; but in place of this is substituted, and admirably substituted, the vigilant supervision of the Commissioners in Lunacy, for within twenty-four hours of the admission of a patient into an English asylum, a copy of the order of the relative or other person, who takes the place of the petitioner in Scotland, and the two medical certificates, must under penalties be submitted to the Commissioners in Lunacy. There is no "merely ministerial" performance of duty here; the slightest omission, flaw, or inaccuracy calls for amendment. Within a given time, or if the facts indicating insanity stated are vague or not sufficiently strong, a further statement of facts will certainly be called for, and if not forthcoming the patient may be summarily discharged. The framers of the Bill of last year seem, while adopting the Scotch procedure in the main, to have been fully alive to the weakness of the "merely ministerial" function assigned to the sheriff in Scotland, for it is expressly stated in the Bill that in order to give the county court judge, magistrate, or justice in England something more than "merely ministerial" functions in cases which require investigation, he is empowered, if he considers the statements in the medical certificates unsatisfactory, to make inquiries, and, if he thinks it necessary, to *visit* the alleged lunatic. The wisdom of the provision giving these increased powers to the civic authorities has been much contested by those who have had the best opportunities of watching the practical working of the Lunacy Acts. At a meeting of the Medico-Psychological Association, held at Bethlem Hospital in May last, this question was fully discussed, and the general feeling elicited during the discussion was that magisterial interference was not desirable in England, but if its adoption by the Legislature should prove unavoidable and unpreventable, that the evil should be minimised to the utmost extent. A resolution was finally agreed upon in this event, as follows: That the function of the magistrate to visit and examine a patient ought to be omitted from the Bill; that the power of the magistrate should be purely "ministerial"; and that, when any doubt on medical questions arose, the magistrate should only have power to direct a further medical examination. Thus the argument with regard to the desirability and the usefulness of the introduction of the magistrate &c. revolves in a circle.

I have, I think, succeeded in showing that the "ministerially" signed warrant of the sheriff in Scotland is a practically useless document in so far as it gives increased security to the liberty of the subject in that country. This is practically admitted in England, for it is proposed in the Lord Chancellor's Bill to give something more than "merely ministerial" functions; whereupon this proposal to extend magisterial powers in England, as compared with Scotland, is at once met by the almost unanimous opposition of those best qualified to judge of the effects of such magisterial interference upon the patient himself, his relatives, and the privacy of domestic affairs; and we are forced to return to the point in the circle from which we started, and the question once more presents itself—Is it or is it not desirable to alter the existing law at all on this point?

A further and important question, however, still remains open for consideration, which is closely connected with the desirability or otherwise of the introduction of the magistrate, and that is the degree in which protection would or would not be afforded under a warrant issued by a magistrate to members of the medical profession on whom the duty might devolve of signing the certificates. Should the magistrate be introduced in any future Bill, and his duties be defined in it to be "merely ministerial," possibly more responsibity would thus be thrown upon medical certifiers or witnesses than if the magistrate were empowered to act in his "judicial" capacity. In connexion with this arises the interesting question, What is the present legally protective value to members of the medical profession of the sheriff's warrant in Scotland? An answer to this from high legal authority would be exceedingly useful in solving many existing doubts on the subject. It may be remarked *en passant* that the Lord Chancellor's Bill as amended in committee contained the following clause, which seems to afford adequate protection to medical practitioners; and a similar clause must of necessity find a place in any future Bill if medical men are called upon under it to perform similar duties, otherwise they will probably be declined: "A medical practitioner who in the manner required by this Act signs any certificate that a person is of unsound mind shall not be liable to any civic or criminal proceeding for signing such certificate, or for any act done with the view of enabling the practitioner to sign the certificate, if the certificate is signed and the act is done in good faith."

No dissentient voice has hitherto been raised to the admirable principle announced of affording facilities for the medical treatment of persons who desire to submit to treatment. Clause 30 provides for voluntary residence in asylums of *any person* who has obtained the previous consent of the commissioners or visitors. This practice has been long in beneficial operation in Scotland, and it is not confined there, as at present it is in England, to persons who have within a period of five years been previously in an asylum under certificate. The same remarks apply to the new certificate of urgency. A clause certainly does already exist in the present English Acts which permits reception of a patient in cases of urgency on one medical certificate, but the steps which require to be taken subsequently neutralise its value. In Scotland the certificate of emergency is frequently used, and it is found very efficacious in enabling dangerous patients to be at once placed under proper care and control for a given period, during which, if necessary, more formal documents can be procured.

Finally, by Clauses 54, 55, and 56 of last year's Bill, power was conferred on justices of county or borough asylums to make such alterations in or additions to the asylum, either by way of detached buildings or blocks of buildings or otherwise, for the purpose of providing accommodation for lunatics not paupers; justices were also empowered to make provision for the reception of pauper and private patients together or in separate asylums, and also to provide separate asylums for patients suffering from any particular class of mental disorder. The powers thus conferred upon justices, although merely permissive, clearly would have enabled them to provide for the poorer classes other than paupers, by annexes &c. to existing county or borough

Digitized by Google

asylums; but the powers seem vague and ill-defined with regard to the provision to be made by justices for some 3321 patients of the upper and middle classes who are now resident in the metropolitan and provincial houses licensed for their reception by commissioners and county justices, the friends of whom would probably object to their removal from private and domestic surroundings suitable to their stations in life to the precincts of a pauper asylum. In introducing his Bill to the House of Lords, the Lord Chancellor, however, remarked that there was nothing to prevent justices purchasing for a fair value the existing licensed houses in which these patients are now under care, and converting them into public institutions.

ST. BARTHOLOMEW'S HOSPITAL.

A CASE OF DOUBLE POPLITEAL ANEURYSM; LIGATURE OF BOTH FEMORAL ARTERIES; RECOVERY.

(Under the care of Mr. MORRANT BAKER and Mr. BRUCE CLARKE.)

THE treatment of double popliteal aneurysm would be carried out by the majority of surgeons in a similar manner to that used in the following case. Some still object to the employment of digital compression before ligature, believing that such treatment injures the vessel and leaves the patient in a worse condition if unsuccessful. But when the pressure is properly regulated and skilfully applied, in cases where the artery at the point of pressure is healthy, no local damage arises, and after-ligature is quite satisfactory. As the risk of operation is increased by the simultaneous ligature of the two vessels, few would be inclined to perform it, although it has been done with success.

For the following notes we are indebted to Mr. Frederick H. Wigmore, house-surgeon.

J. P——, aged thirty-eight, a compositor, was admitted into Darker ward on Dec. 28th, 1885, suffering from double popliteal aneurysm. Three months previously he first noticed in the left popliteal space a pulsating tumour about the size of a walnut, which had gradually increased in dimensions. Two months ago he experienced very considerable pain in the right popliteal space, and his knee-joint was treated as for rheumatism. There was no history of individual injury or family history of aneurysm, but there was a distinct account of syphilis ten years ago.

On admission the man was pale and badly nourished, with numerous pits of small-pox on his face. In the left ham, and situated just behind the knee-joint, was a pulsating swelling about the size of a hen's egg. The whole tumour was very soft, and could be made almost completely to disappear by slight pressure when the common femoral was controlled by the finger; and if, while the sac was still compressed, the common femoral was allowed to go free the aneurysm was found to fill by gradually increasing leaps and bounds, three pulsations at least being required to distend it to its usual limits. The pulsation was expansile, and synchronous with the heart's beat. There was no thrill to be felt by the hand placed upon it, or bruit when the stethoscope was applied. The pulse in the tibial arteries was feeble. In the right leg there was a large and feebly pulsating tumour as large as a man's clenched fist, extending from between the hamstring tendons under the inner hamstrings as far round in front as the inner border of the rectus muscle, and on the outer side to the tendon of the biceps. There was a distinct thrill to be felt and bruit to be heard in the tumour, which was very painful. The patient had been losing flesh, and was manifestly very weak. His appetite was bad. The temperature was just above normal. The bowels were rather confined. The pulse at the wrist was strong, but intermittent. Urine: sp. gr. 1020; acid; contains phosphates, but no albumen or sugar. Both radial and tibial arteries were hard. An examination of the chest and abdomen disclosed the following physical signs:—Movements fairly good; vocal vibrations increased at right apex; no thrill to be felt. Heart's dulness normal. Right apex slightly impaired to percussion. A somewhat flatter note to be obtained in the second right intercostal space near sternum and over aorta. On auscultation expiration at right apex was found to be prolonged and tubular; vocal resonance increased over same area. Heart sounds: first sound thumping at apex; second pulmonary and second aortic sounds loud and forcible; aortic sounds conducted some distance from sternum; first aortic sound soft and altered, but not a murmur. Posteriorly the physical signs corresponded with those in front of the chest. No crepitant sounds anywhere. Liver and spleen not felt. Pulsations of abdominal aorta forcible and pronounced.

Since pressure upon the common femorals easily controlled the pulsations in the aneurysms, it was determined to try the effect of such pressure before resorting to ligature of the artery. Accordingly, at 3.30 P.M. on Jan. 2nd, a Holden's shot-bag containing 9 lb. was applied (a finger intervening) to the right common femoral, high up. The pulsations were readily controlled, and there was an increase in hardness of the sac. At 6.45 P.M. the patient was much exhausted, and the pressure was discontinued. The pulsation was almost checked, and the sac was very hard. The pulsation recommenced, however, in a very short time.

Jan. 3rd.—Pressure was applied from 9 A.M. to 1 P.M. and from 3 to 7 P.M. The result was not satisfactory, the pulsations being as strong as ever. Complains of some pain in the right tumour. Pulse 100; temperature subnormal.

5th.—On the right side the aneurysm seems to have extended a little up the limb, and pulsation appears to be strong over a wider area. Complains of some numbness.

6th.—2 P.M.: A discoloured patch observed on the skin over the right aneurysm. Œdema behind ankle. The aneurysm has extended slightly up the thigh. The patient was consequently taken down to the operating theatre, and, he having been placed under ether, the right femoral artery was tied by Mr. Morrant Baker at the apex of Scarpa's triangle. The artery was tied in two places with kangaroo-tendon ligatures and divided between, there being an interval of about three-quarters of an inch between the two ligatures. A small drainage-tube was inserted, and the wound, having been cleansed with warm carbolic lotion, was closed with silver sutures. The whole was dressed with sanitas oil (1 in 30 of olive oil), lint, and antiseptic gauze. The limb was carefully wrapped in cotton-wool, and hot bottles were placed in the bed.

7th.—Passed a good night. Has taken food well. Limb warm; no pulsation to be detected in the aneurysm. The tumour on the left side remains the same.

8th.—Toes warm and moist; blush returns after pressure. Temperature normal.

9th.—Aneurysm pulsates; has diminished in girth three quarters of an inch since the operation; wound dressed and looking well; sensation of limb unimpaired. The aneurysm of the left leg seems to have extended upwards and downwards in the popliteal space. No discolouration of the skin or œdema of the leg. Girth, 12¾ in.

11th.—Wound dressed and doing well. No change in left aneurysm.

12th.—Drainage-tube withdrawn, and not replaced. Left aneurysm appears to have extended, and the skin over it is slightly discoloured. Temperature subnormal. On account of the rather sudden alteration in the aneurysm, the left femoral artery was, in the absence of Mr. Baker, tied by Mr. Bruce Clarke near the apex of Scarpa's triangle in two places, and divided between. Kangaroo tendons were used as ligatures. A drainage-tube was inserted, and a dressing of moist carbolic gauze was applied.

14th.—The right wound shows some signs of slight discharge from the track of the drainage-tube; elsewhere it is healed. The left wound had its drainage-tube removed. The temperature has gone up to 101·5°; pulse 120.

15th.—Right wound looking exceedingly well; left wound appears healthy; no pulse in either aneurysm; sensation not impaired, and toes warm. Feels comfortable.

19th.—Right wound quite healed, and dressing discontinued.

20th.—Left wound is breaking down; pus discharging;

Digitized by Google

dressings blood-stained (venous). Temperature fluctuates between 98° and 100°.

21st.—Dressing on left side still blood-stained. A good deal of sanious pus expressed from the wound. Syringed with carbolic lotion, and dressed with carbolic gauze.

23rd.—Superficial veins of right leg somewhat distended. A vessel pulsates over the left aneurysm. Left wound improving.

28th.—Left wound much improved; some hardness surrounds it; discharge less. Temperature natural.

29th.—Left wound much better, but still discharges slightly; some hardness remains round wound; no pain; no rise of temperature; general condition excellent.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

AORTIC REGURGITATION, WITH ACUTE CONGESTION OF THE LUNGS, RELIEVED BY FREE BLEEDING.

(Under the care of Dr. SAMUEL WEST.)

ALFRED P——, aged twenty-five, was admitted on Dec. 4th, 1885, with extreme dyspnœa, due to cardiac mischief. Nine months ago a ton of clay had fallen out of the side of a tunnel upon his chest. He lay for two hours unable to move, and had to lay up for two days, after which he experienced no further distress until three months ago. He was then seized suddenly with shortness of breath, but without pain. This had got worse since. He had never had rheumatic fever, but his work was hard and he had drunk heavily. His feet had gradually swollen, and he had been much worse for the last fourteen days.

On admission the dyspnœa was extreme, and the patient was somewhat cyanosed. There was much œdema of the legs. A double murmur was heard over the whole præcordium, which was thought to be probably friction. The patient was put to bed and slept quietly till 8.30 A.M., when he was suddenly seized with severe dyspnœa. He was greatly distressed and excited, throwing himself about. He became more and more cyanosed, and spat up some bright bloody sputum. The lungs became rapidly engorged, and he seemed to be dying. It was clear that he had an attack of acute congestion of the lungs of cardiac origin, and that he would die unless relieved in some way. The sister in charge, a woman of thirty years' experience, said he was lost and nothing could save him. It was decided to bleed him. This was done at once to the extent of nearly a pint from the arm, and as the blood flowed the blueness diminished and the breathing was relieved. A little opium and ether were given, and in an hour all immediate danger was past. The pulse, which before bleeding was thumping and hard, became slower and softer, and by midnight the sputum had ceased to be blood-stained.

Dec. 5th.—Heart's action quieter; loud double aortic murmur audible.

6th.—Patient better. Cardiac dulness extends to the right of the sternum, and upwards to the third rib; the apex is in the mid-axilla in the sixth space. The liver is much enlarged downwards and painful. The œdema is less, and the bronchitis and the cyanosis are almost gone.

From this time the improvement was continuous up to a certain point, the patient of course remaining in bed, but being comfortable and sleeping and eating well. He remained in a stationary condition for about a month, and then the œdema began to increase and the patient to slowly but steadily lose ground, and he finally died on Jan. 22nd, without further symptoms of importance. The temperature had risen to 101° during the last week of life.

The post-mortem showed disease and rupture of the aortic valves. The left anterior was chiefly affected; it was torn, and a free tag had rubbed the septum and led to endocarditis, with the formation there of a small aneurysm.

Remarks by Dr. WEST.—The acute symptoms on admission I attributed to sudden failure of the heart, the rupture of the valve having taken place three months before, according to the history; as no infarct was found in the lungs this explanation was probably correct. The great interest of the case lies in the effect of the bleeding. The patient was at the time actually dying, and it seemed almost hopeless to do anything; but the only thing was bleeding, and that copiously. The effect was like that of a charm, for as the blood flowed the threatening symptoms disappeared one by one, and the danger passed away. It may seem heroic to bleed freely in aortic disease, and such treatment would be in place only in exceptional cases, but I have no doubt that in this case the prolongation of life for seven weeks may be rightly referred to the treatment adopted. Bleeding in the chronic pulmonary of mitral disease to relieve a dilated right ventricle is a recognised and not unusual method of treatment. The present case shows that it may be equally in place in appropriate cases of aortic disease.

EDINBURGH ROYAL INFIRMARY.

ANEURYSM OF THE ABDOMINAL AORTA.

(Under the care of Dr. BYROM BRAMWELL.)

G. S——, aged thirty-two, a foreman labourer, presented himself on Jan. 2nd, 1886, complaining of pain in the back and a swelling in the abdomen. The patient, a very big and formerly very muscular man, who was now somewhat pale and flabby-looking, stated that the pain in the back commenced several months ago, and that for the past five months he had been under treatment (rest and iodide of potassium, sixty grains three times daily) in the Sunderland Infirmary. On inquiry, it was elicited that he had been subjected to very heavy work and strain, that at one time he had drunk freely, and that he had had a soft chancre and bubo, but no secondary syphilitic symptoms.

Physical examination.—A large pulsating tumour, the pulsation being lateral and expansile, extended from the zyphoid cartilage to within half an inch of the umbilicus, and was situated for the most part to the left of the middle line. On auscultation, a well-marked systolic murmur was audible over the tumour in front and on both sides of the spine (louder on the right than on the left side) behind. The patient stated that he was somewhat short of breath on exertion. The right pupil was smaller than the left; there were no symptoms of intra-thoracic pressure; the pulses were equal, and the heart seemed normal. No dulness was detected over the manubrium sterni, but some pulsation could be felt deep down in the supra-sternal notch. When the patient lay on his back with his head low, both heart-sounds were very distinctly heard over the manubrium sterni, and there was at the same spot very distinct bronchial, almost tubular, breathing; there was also, when the patient was in this position (flat on his back with the head low), some apparent pulsation in the veins at the root of the neck. When the patient sat up and leaned the head forwards, the tubular breathing and venous pulsation in the neck disappeared and the localised loudness of the heart-sounds was much less audible.

Remarks.—Dr. Bramwell emphasised the fact that when a robust and apparently healthy man complains of a fixed pain in the back, an aneurysm of the abdominal aorta should always be suspected; the suspicion was strengthened if the patient had led a laborious life, had been subjected to heavy strains, had drunk hard, or had had syphilis. It must be remembered that a cicatrix in the groin or in the penis, though presumptive, was not certain evidence of syphilis. In this case there could be no doubt as to the nature of the condition, but the diagnosis of an aneurysm of the abdominal aorta was not always an easy matter. A case was mentioned in illustration of the difficulties of diagnosis in which the aorta was encased in a mass of cancerous glands; in that case there was: (*a*) very severe pain in the back; (*b*) a tumour fixed to the spine, localised in the course of the aorta, and presenting most distinct lateral and expansile pulsation; together with (*c*) a systolic murmur audible both over the tumour in front and over the back behind. The physical signs of an aneurysm of the abdominal aorta were, in fact, exactly simulated; and it would have been impossible to have arrived at a correct diagnosis had it not been for the fact that a lump, the size of a small orange, evidently a malignant growth of rapid formation, was situated just above the left clavicle. A systolic murmur was very generally present in aneurysms of the abdominal aorta; this was not the case in aneurysms of the thoracic aorta; in that condition, provided that the cardiac valves were healthy and there was no murmur conducted from the heart, a murmur was more often absent than present; a murmur might be said to be absent under such conditions in at least 50 per cent. of the cases. It must not, however, be supposed that a systolic murmur heard over the abdominal aorta was distinctive of aneurysm. This was more especially the case when auscultation was made from the

Digitized by Google

front, in which position the mere pressure of the stethoscope, by constricting the vessel, was sufficient to produce a murmur. When, however, auscultation was made from behind, this source of error was avoided. If a murmur were heard in the vertebral groove behind, and if the observer were satisfied that it was not propagated from the chest, but generated in the abdominal aorta itself, it was very strong, but by no means conclusive, evidence of aneurysm. In the above case the murmur was heard more loudly in the right than in the left vertebral groove; this probably showed that the aneurysmal sac was attached to the right side of the spinal column, notwithstanding the fact that in front this aneurysmal tumour was placed to the left of the middle line. Dr. Bramwell did not feel quite certain that in auscultating the back he might not have mentally reversed the two sides by mistaking the right for the left, as one is sometimes apt to do; if this had been the case, the error would probably have been brought to his notice by some of the students who subsequently examined the patient. The exact cause of the shortness of breath which the patient felt on exertion was not definitely ascertained. The tubular breathing and localised loudness of the heart-sounds over the manubrium sterni, and the venous pulsation at the root of the neck, were possibly due to the presence of a small aneurysmal sac filled with solid coagula under the upper part of the sternum. A case was referred to in which somewhat similar physical signs were proved on post-mortem examination to be due to this cause. This was merely advanced as a suggestion and not as a diagnosis. As the result of a single and somewhat hurried examination, Dr. Bramwell did not feel himself able to express a positive opinion on the point. There was no dulness on percussion. The pulsation in the supra-sternal notch was not of much corroborative value; it might be due to simple dilatation of the aortic arch, and was, indeed, not unfrequently present in perfectly healthy persons.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Harlequin Fœtus.—Cardiography.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair.

Mr. J. B. SUTTON read a paper on a case of General Seborrhœa or "Harlequin" Fœtus. The case was a typical example of what is usually known as the "harlequin" fœtus. Although the condition is a very rare one, it has received a variety of names; but as the term "general seborrhœa" expresses the pathology of the disease, and that of "harlequin fœtus" is an excellent clinical expression, both have been retained. Details of the microscopical characters of the skin were given, and an argument was furnished for regarding the affection as being due to abnormal formation of the vernix caseosa, which, instead of being shed into the amniotic fluid, forms concrete masses which adhere to the skin. The paper ends with an appendix containing references to all the recorded cases known to the author.—Dr. COLCOTT FOX said that all authors were of opinion that the disease was limited to the epidermis. No doubt there were cases of general seborrhœa which differed, however, in the circumstance that the termination is not necessarily fatal, which is the invariable result of the harlequin fœtus. Kyber called it a diffuse keratosis; a purely developmental anomaly of the epidermis. Charles Robin and Chambard, with all recent authors, concurred in this view. Kyber said the disease began before the development of the sebaceous glands. What alliances had this condition with true ichthyosis? Though Hebra and Kaposi had asserted that true ichthyosis began in all cases some time after birth, yet Dr. Fox felt sure that this was incorrect, for he knew of some cases in which the ichthyotic skin was certainly congenital. He believed that true ichthyosis and the harlequin fœtus were of identical nature.—Dr. RADCLIFFE CROCKER had examined the skin in Mr. Sutton's case, taken from the scalp and chest, and he dissented from the author's view of the microscopic appearances. The disease was an ichthyosis. There was no kind of seborrhœa that produced any such change; and in seborrhœa the skin beneath was perfectly healthy. Hebra asserted that in the harlequin fœtus there was not the enlargement of the papillæ that pertained in ichthyosis, but Dr. Crocker had found the papillæ much elongated in Mr. Sutton's specimen. An extension downwards of the inter-papillary pillars of the rete Malpighii was also observed. Further, the horny layers dipped down and followed the conformation of the papillary layer. Dr. Crocker believed that ichthyosis congenita was a proper name for the disease.—Dr. CHARLEWOOD TURNER also agreed with the conclusions of Dr. Fox and Dr. Crocker. A defective secretion of sebum led to the accumulation of epidermal scales. He considered that there was a defective development, and not a hypertrophic condition.—A FELLOW, after referring to the uncertain state of knowledge concerning the source of the liquor amnii, asked whether the liquor amnii were deficient or altered in any way in Mr. Sutton's case.—Mr. J. B. SUTTON admitted that there was room for a difference of opinion as to the microscopic nature. The masses on the skin were most marked where the vernix caseosa occurred in the greatest quantity, and the disease developed from the fourth to the eighth month of fœtal life when the sebaceous secretion was most active, so he considered that there was an excessive amount of sebum in the masses on the skin of the harlequin fœtus.

Dr. PAUL CHAPMAN communicated a paper on Cardiography, with special reference to the relation of the duration of the Ventricular Systole to that of the Diastolic Interval. The author, after discussing previous works on the subject, especially that of Dr. A. H. Garrod, gave a table of measurements, taken from healthy individuals, of the duration of ventricular systole and diastole in each cardiac revolution, for every increase of five beats in frequency per minute between 45 and 150. He showed that in the human subject the duration of systole diminishes by a constant quantity as the pulse frequency increases, the constant diminution being ·0085″ for every increase in frequency of five beats in the minute. He gave this table as one which might be safely used by future workers as a basis of comparison for estimating departures in disease, while emphasising the fact that the duration of ventricular systole may vary, in health, from the measurements given in his table within the limits of ·02″; an increase being most common with the lower pulse rates. A decrease at the higher rates extending beyond the limit above mentioned must be considered abnormal. The influence of increase or of diminution of blood-pressure on the duration of ventricular systole was discussed. The importance of the rapid diminution in duration of systole providing the heart with an increased amount of rest was pointed out; and it was remarked that a high pulse frequency is not necessarily attended with rapid cardiac failure; though in some cases rapid failure did quickly ensue. Marked departures from the normal relative duration of systole and diastole were then noticed. The results of experiments with digitalis and convallaria majalis were given, and illustrative tracings shown. The instrument employed in making the observations was the air-containing cardiograph of Dr. Burdon Sanderson.—Dr. BROADBENT considered that the profession was indebted to Dr. Chapman for the labour that he had bestowed on the subject. The relation in time of the systole to the diastole was of much importance; there were cases in which no cardiographic tracing could be obtained. He had been interested in the subject before the appearance of Dr. Garrod's paper. He believed that the relative duration of systole and diastole could be gauged accurately by the stethoscope, and this had been his special method of observation. The clinical interest and prognostic importance of the gradual diminution of the duration of systole were remarked upon. The cardiograph gave tracings which were consistent with stethoscopic observation. He considered, in opposition to Dr. Chapman, that blood-pressure had a great deal to do with the diminution of the duration of systole. In fevers the diminution was due to diminished resistance in the peripheral circulation. In some pyrexiæ no diminution occurred, as in scarlet fever, during the early stage, with a frequent pulse, when the arteries were not relaxed. The normal rhythm might be lost, and auscultation reveal the complete "tic-tac." The diastole might be actually shorter than the systole. Similar phomomena were met with in acute renal disease, in which a slight elevation of temperature was accompanied by considerable increase in the peripheral resistance. In some cases of acute albuminuria the heart rhythm varied almost from day to day; here cardiac exhaustion played a part. He had also observed the lengthening of systole gradually diminish as the heart

Digitized by Google

gained power. In cases of heart failure in diphtheria, when the interval between the first and second sounds was diminished, we had an early and very significant sign of the cardiac exhaustion. The precipitate following of the second sound on the first sound was due to an imperfect emptying of the ventricle, and he also conjectured that the second sound might appear before the ventricle had ceased to contract. Controlled by careful stethoscopic examination, he believed that cardiographic tracings were of considerable value.—Dr. A. E. SANSOM spoke of the value of Dr. Chapman's observations. He had used the cardiograph clinically for many years past. In his early observations he had used Jalabin's instrument, but later Pond's sphygmo-cardiograph. The cardiograph was, in his opinion, of much practical value. It was possible to distinguish mitral stenosis from aortic regurgitation with a thrill by means of the cardiograph. This he had verified in two recent cases. In mitral stenosis the diastolic interval was much elongated in the ratio to systole, as 1 to 1·8. This was regarded as an important point in the diagnosis of mitral stenosis, together with marked irregularities in rhythm. In a case of mixed aortic and mitral regurgitation the ratio of systole to diastole was 1 to 0·3. Digitalis might be very harmful in some cases of aortic regurgitation by prolonging the duration of the diastole.—Dr. ANGEL MONEY, working with Gowers' cardio-sphygmograph, had come to the following conclusions: That the cardiograph was valuable as a record of the mode of action of the myocardium in some cases of heart disease, but it was an incomplete record. Careful auscultation and palpation were of more value in determining the state of the myocardium, and, consequently, in giving a prognosis. Cardiograms were, in his opinion, of but little value in diagnosing the nature of valvular lesions. Mitral stenosis frequently gave an almost special cardiogram, but even this might be simulated by a healthy heart under the influence of emotional excitement. He possessed cardiograms taken from different forms of valvular lesion which could not be distinguished from one another.—Dr. CHAPMAN, in reply, could not agree with Dr. Sansom that the lengthening of the diastole was absolutely characteristic of mitral stenosis; lengthening might happen from many other causes than this form of valvular lesion. He concurred with Dr. Money in thinking that the cardiograph revealed and recorded the state of the myocardium as to muscular or nervous exhaustion. He would employ it clinically rather with a view to prognosis than diagnosis.

MEDICAL SOCIETY OF LONDON.

General Annual Meeting.—Spastic Paralysis.

THE annual general meeting of this Society was held on March 1st, at 8 P.M., after which the ordinary meeting took place, Dr. W. M. Ord, the retiring President, in the chair. The treasurer, Mr. A. E. Durham, read the report of the financial affairs, which showed that the Society was in a prosperous condition. The hon. librarian, Dr. W. H. Allchin, read a report on the state of the library, which had now been fully catalogued. Dr. Ord and Mr. Durham had each contributed £20 towards the expenses of the library. Dr. Kingson Fowler read the report of the trustees of the Fothergillian Fund. The subject of the Fothergillian Prize has not yet been selected for the year 1888. Mr. Arthur E. Durham moved, and Dr. Sutherland seconded, a vote of thanks to Dr. W. M. Ord on the termination of his presidency. Mr. Noble Smith moved, and Dr. Allchin seconded, the vote of thanks to the retiring vice-presidents and other retiring members of the Council. Dr. Coupland proposed, and Mr. Harrison Cripps seconded, the vote of thanks to the retiring secretary, Dr. J. Kingston Fowler. This resolution was carried with acclamation, and Dr. W. M. Ord spoke of the very valuable services that Dr. Fowler had rendered both to the President and the Society at large. The report of the scrutineers of the ballot (Drs. Hayward and Sutherland) showed that the gentlemen nominated by the Council for office for the ensuing year had been unanimously elected. (*Vide* THE LANCET, p. 400.)

Dr. W. HUGHES BENNETT read a paper on Spastic Paralysis, which appears *in extenso* in our present issue.—Dr. HUGHLINGS JACKSON said he believed he was responsible for the view that increased muscular action of spastic states might be attributed to loss of cerebral influence. Abolition of the functions of local inhibitory centres of the spinal cord was a hypothesis advanced by Gowers, and accepted by him. He still was of opinion that some forms of rigidity were due to unrestrained cerebellar influences, as, possibly, in the rigidity of paralysis agitans. Mention was made of a case of epileptic attacks in which the clonic spasm was almost limited to the left arm, yet after the fits, which were very numerous, the knee-jerk was first abolished on that side, though later on it increased and ankle-clonus developed; even at the onset of a fit the knee-jerks were exaggerated, although the legs were not affected with clonic spasm.—Mr. VICTOR HORSLEY said that in artificial degenerative processes the same exaggerated phenomena pertained as in disease in man. He did not think the hypothesis of Gowers—that of miniature inhibitory centres of the spinal cord—would help to explain matters. Richet had worked very fully at the phenomena of hypnotism. The paper by Dr. Bennett raised the question of the connexion between higher and lower centres.—Dr. ANGEL MONEY advanced reasons for thinking that the hypothesis of Gowers might prove of value in understanding the phenomena of temporary rigidity.—Mr. HARRISON CRIPPS spoke of the mechanical contraction of muscles in old cases of spastic paralysis.—Dr. W. M. ORD hoped that the discussion would tend to throw light on the clinical value of the phenomena.—Dr. W. B. HADDEN said that he had noted ankle-clonus in a case of pernicious anæmia; the necropsy showed that there was lateral and posterior sclerosis. In a case of chronic right hemiplegia and hemi-spasm he had detected no change in any part of the nervous system, nor also in a case of fatal tetany. He had seen ankle-clonus in the sound leg when a patient had been laid up with fracture of the opposite leg. In his opinion sclerosis did not necessarily produce rigidity or exaggerated reflex phenomena; on the other hand, we might have the phenomena of hyperkinesis in the absence of lateral sclerosis.—Dr. ORD said that the case of pernicious anæmia already alluded to occurred in a robust and ruddy railway guard, whose disease began after a curious shock which the patient described as ascending up the left arm and down the left side. He was interested to know how far the anæmia might have been dependent on the spinal lesions.—Dr. BEEVOR considered that spasm and increased deep reflexes might not be due to the same cause; they did not always appear together; the latter frequently preceded the former. After ordinary epilepsy he had observed ankle-clonus and increased knee-jerks on the side most convulsed.

Aneurysm of Aorta.

At an ordinary meeting held on Monday last, Mr. R. Brudenell Carter, F.R.C.S., the new President, in the chair,

Dr. W. H. WHITE read notes of a case of Aortic Aneurysm that occurred in a married woman aged forty-three. When first seen she was suffering from intermittent pain and vomiting, possibly due to a gall-stone; she had suffered once seven years previously from the same complaint. On Feb. 20th, 1885, the urine contained bile, and Dr. White noted the following symptoms: Left pupil smaller than the right; right and left jugular veins were swollen; the left radial pulse was weaker than the right. There was a distinct thrill about the second right costo-sternal articulation, and also slight pulsation in the supra-sternal notch and first right intercostal space; about the same area there was dulness and a loud to-and-fro murmur. There was no sign of pressure on the recurrent laryngeal nerve and no dysphagia; the left chest expanded less than the right. Profuse perspiration and thirst were marked symptoms at times. Later in the course of the case there was dulness of the left side, with absence of vocal fremitus and breath sounds. Hæmoptysis was occasionally present. The pain at times called for the administration of hypodermic injections of morphia. The patient died in a state of collapse, accompanied by profuse hæmoptysis, on Jan. 21st, 1886. Rest in bed, low diet, and iodide of potassium were the agents used in treatment. Ergot lessened the volume of the pulse, and appeared to control the hæmorrhage. At the necropsy some fluid was found in the left pleural cavity. The heart was slightly enlarged, its cavities empty, and the left ventricle somewhat hypertrophied. The aorta was greatly distended, much thickened by atheroma, and sacculated. The left bronchus was blocked, and the left lung collapsed; the left pulmonary artery was also somewhat pressed upon. There was a fibroid tumour of the uterus. The uterus, ovaries, and peritoneum were the seats of round-celled sarcomata, which also existed in the left lung. A

Digitized by Google

round-celled growth also occurred in the adventitia of the aorta. The aneurysm had extended backwards and to the left, causing erosion of the vertebræ. — Dr. DE HAVILLAND HALL read notes of a case of Aneurysm of the Aorta in a man aged thirty-six, in whom there were four distinct aneurysms. The voice was affected early in the disease. The patient was first seen on July 1st, 1885. There were pain in the shoulder, headache, dyspnœa, deficient entry of air into the left lung, absence of pulsation in the left axillary, brachial, and radial arteries, and the right brachial was very rigid. There was a cataract of the left eye. Percussion revealed a dull area at the apex of the left lung; later on, pulsation and bulging developed at this site. Feeble pulsation in the left radial and brachial arteries returned. The dulness increased in area. Pain was experienced in the right mammary region. Dulness appeared in the second right interspace. A diastolic bruit was heard at the base of the heart, which varied in distinctness from time to time. Death ensued on Feb. 12th, 1886. At the necropsy sixteen ounces of serum were found in the left pleural cavity and one ounce in the pericardium. A tumour as large as a cricket-ball was detected at the top of the left side of the thorax. Both lungs were œdematous. An aneurysmal dilatation was detected at the first part of the arch of the aorta the size of a Tangerine orange; another large aneurysm was present at the junction of the second and third parts of the aorta, nine inches in circumference. The left pneumogastric nerve was destroyed. The left carotid ran along the wall of the large aneurysm for three inches. The aortic valve allowed of slight regurgitation. There was a large dilatation of the first part of the arch, and the third aneurysm opened out of this. The diagnosis was made by Dr. Hall as soon as the laryngoscopical examination revealed paralysis of the left vocal cord. In treatment with iodide of potassium, he advocated the same principles that Dr. Balfour had recently laid down in THE LANCET.—Dr. C. THEODORE WILLIAMS referred to the stridulous character of the voice that obtained in some cases of aneurysm—a stridor which was particularly remarkable when the patient coughed. Cancer of the mediastinum might give rise to paralysis of the left vocal cord.—Dr. W. M. ORD thought the interest of Dr. White's case was chiefly pathological. Dr. de Havilland Hall's case appealed more to the clinical physician. A murmur at the site of the orifice of the pulmonary artery was occasionally present in cases of aneurysm of the sinus of Valsalva. In all cases of alteration of the voice the larynx should be examined. In a large number of cases the vocal cord was fixed in the position of adduction, and not in the cadaveric position. Dr. Ord had taken tracings from aneurysms which, from having fluid contents, became solid and yielded tracings with the cardiograph similar to those obtained by Dr. Richardson.—Dr. S. WEST asked whether Dr. White considered there was any causal relationship between the sarcoma and the aneurysm. The number of cases in which blood-casts were expectorated and the patient lived for a long time was not great. In a case of phthisis he had met with those blood-casts.—Dr. D. W. FINLAY spoke of the value of iodide of potassium in the treatment of aortic aneurysm.—Dr. A. ROUTH alluded to the occurrence of menstruation within ten days of death, when the ovaries were so much diseased.—Dr. WHITE, in reply, repudiated the notion that the aneurysm was in any way causally related to the sarcoma.—Dr. DE HAVILLAND HALL said in his case the left vocal cord was in the cadaveric posture because both adductor and abductor muscles were paralysed; there was no stridor, and none was to be expected, as the rima was freely open.

ACADEMY OF MEDICINE IN IRELAND.

Dentigerous Cyst.—Perforating Ulcer of the Stomach.—Bright's Disease.

AT the meeting of the Pathological Section on Jan. 15th, MR ARTHUR BAKER read a paper on a case of Dentigerous Cyst occurring in the lower jaw of a boy aged sixteen. The tumour had existed for six months previous to operation. When opened an unerupted canine tooth was found at the bottom of the cyst. This tooth showed the malformation known as dilaceration of its root. The importance of diagnosing cases of this disease was shown by the fact that in a similar case, where the cyst was not recognised, one-half of the jaw had been excised.—Mr. STORY said there was only one other case on record in which a dilacerated tooth was found occupying the cavity of one of those so-called dentigerous cysts.—Dr. MACSWINEY said cases of teething were sometimes met with in children, where it seemed impossible for the unaided powers of the child to erupt the tooth, and on such occasions he had seen a soft tumid condition over the tooth, which had not escaped through the gum, and which, when incised with a gum lancet, had given exit to a clear viscid fluid. There was in such cases a sort of cyst under the unbroken gum and resting on the crown of the tooth.

Dr. FINNY exhibited an extremely rare specimen of an Oval Ulcer (one inch by half an inch) of the Stomach, situated on its anterior wall two inches and a half from the cardiac and two from the lesser curvature, leading up to and perforating the heart. The floor of the ulcer was the muscular structure of the under surface of the left ventricle, about one inch from the apex; and the ulcer, after perforating the stomach, had eaten through the diaphragm and the pericardium. The stomach was adherent to the diaphragm round the ulcer, but the adhesions were very slight and of recent date. The pericardial sac had been obliterated by adhesive inflammation, and over the whole of the left ventricle the adhesions were very dense. Through the larger of several interstices between the exposed muscular tissue of the apex a probe could be passed upwards, and was found to enter the left ventricle behind a musculus papillaris attached to the posterior mitral curtain. The patient from whom the morbid specimen was removed had died of syncope on December 9th, 1885, preceded by the passage of blood from the bowels. Strange to say, there was no hæmatemesis. At the necopsy the stomach and the whole intestinal canal were found full of liquid blood, the stomach alone containing two quarts. The source of the blood was the left ventricle, and it is probable that it escaped into the stomach during both systole and diastole. The fatal steps in the pathological history of the case were: (1) Ulcer of the stomach, of unknown duration; (2) rheumatic pericarditis and adhesions of the left ventricle to the diaphragm, with obliteration of sac; and (3) recent activity in the ulcer perforating into the muscle of the heart. The general muscular structure of the heart under the microscope was perfectly normal, and free from fatty degeneration, except the fibres at the floor of the perforation, which were granular and broken down, though free from all fat. Dr. Finny referred to the anatomical relations of the liver and stomach to the diaphragm, and stated by observations made, that while, in the majority of instances, the liver by its left lobe entirely separates the stomach from the portion of the diaphragm to which the pericardium is applied, there are exceptional specimens where the left lobe of the liver is small and pointed, where a small triangular portion of the extreme front of the pericardial aspect exactly corresponds to the anterior wall of the stomach in the very position of the ulcer present in this case. There are three similar cases recorded in Vienna: the first by H. Chiari in 1880, the second by F. Brenner, and the third by Oser in 1881; and each of these observers, like Dr. Finny, seemed to have been unaware of the other reported cases.—Dr. FRAZER had seen two cases of gastric ulcer, both of which occurred in young females, and were attended by rupture. In both the patients survived for a time—one for some years. He was enabled, by the recurrence of the rupture in both cases afterwards, and by circumstances brought under his notice after death, to verify the fact that the ulcers had perforated the stomach and had afterwards healed.—Dr. DUFFEY said he had observed a case of ulcer of the stomach in which an opening was formed into the lungs, causing a gangrenous abscess. He presented the specimen to the museum, and it was now on the table of the College of Surgeons. The case reported by Professor Chiari occurred in a woman seventy-one years old. That of Professor Oser was in a woman of the same age. Brenner's case occurred in a woman of fifty-five.—Dr. HENRY KENNEDY said, according to his experience, when the ulcer was on the anterior wall of the stomach, the suffering was very much less than in other cases, and was also intermitting. On the other hand, when the ulcer was down near the pylorus, the pain was nearly constant on the occasions of taking food.—The PRESIDENT remarked that Dr. Finny, speaking of the manner in which the ulcer, after perforating and causing an adhesion of the pericardium, made its way to the ventricle of the heart, laid stress on what he called solution by the gastric juice of the muscular wall of the heart. That seemed rather a startling novelty in

Digitized by Google

pathology, and he should prefer to arrive at some other explanation of the fact. The idea of solution by gastric juice was suggested by Chiari's case, in which it was stated that the muscular fibre of the heart round the situation where the rupture occurred was in a condition of fatty degeneration. Unless there was some very good evidence that the solution in Dr. Finny's case was caused by the gastric juice, he would incline to think that some form of degeneration was present also. Hardly any part of the abdominal viscera was subject to so much irregularity as to position, size, and shape as the left lobe of the liver. Therefore what had occurred in Dr. Finny's case did not present any great difficulty to his mind.—Dr. DUFFEY said there was one circumstance mentioned in Chiari's case which, although no weight was attached to it by the reporter, might be of importance—namely, that in the wall of the sac close to the opening into the stomach a hard brittle mass was found, which chemical examination proved to be composed chiefly of silicates, and which was probably a piece of glass that had been accidentally swallowed.—Dr. MACSWINEY said that solution of tissue by gastric juice was only possible after there had been necrosis of the tissue. In Dr. Finny's case a portion of the pericardium might have become dead tissue.—Dr. FINNY, in reply, said in his case the specimen contained no foreign body. He thought the fact of a chamber having been formed between the heart and the pericardiun showed that probably a gastric ulcer first formed the abscess, and that it opened from the stomach, forming a smaller one underneath the diaphragm, and thence reached the pericardium. Having regard to the slight character of the adhesion between the outer surface of the stomach and the diaphragm, he did not think the passing of the ulcer through the diaphragm could have set up such pericarditis as was found in the case. He thought that pericarditis was due to a rheumatic attack which had preceded the perforation of the diaphragm by the ulcer from the stomach. Nor did he see any difficulty about the solution of the muscles of the heart by the gastric juice. Dr. Purser and Dr. Bewley, who had examined the floor of the ulcer and the granular muscular tissue of the heart, would bear him out in the statement that not the least appearance of fatty degeneration was exhibited by the portions of those parts that were examlned under the microscope. The base of the ulcer and the muscular tissue of the heart were turned into a granular débris, which was the result of the solution. The rest of the heart was perfectly healthy, and showed no sign of fatty degeneration whatever. Nor did he see why the heart should not have suffered from the action of the gastric juice, when they saw that the tendinous portion of the diaphragm, which opposed the progress of the ulcer, was dissolved by the gastric juice at the floor of the ulcer. Having thus gone through the diaphragm, which was of its full thickness, the gastric juice might have acted in a similar way on the muscular tissue of the heart.

Dr. A. W. FOOT showed Kidneys as representative examples of the last stage of parenchymatous nephritis when the organs have undergone atrophic changes. They exhibited the variety of Bright's kidney called by Dr. G. Johnson the "small fatty kidney." The specimens were obtained from the body of a labouring man of thirty-three years of age, who had been habitually exposed to the cold and moisture of the Wicklow mountains in which he lived.

CAMBRIDGE MEDICAL SOCIETY.

AT the meeting held on January 8th the following communications were made.

Salivary Calculus of Unusually Large Size.—Mr. CARVER showed this specimen, which he had removed from a man aged seventy. It formed a swelling in the floor of the mouth to the right of the middle line, and just behind the sublingual gland, and when explored with a needle was found to be of stony hardness. It was easily removed with scissors. The patient had only noticed some tenderness there for about five or six weeks. There was no enlargement of any of the salivary glands or other symptoms. The stone was ovoid in shape, pointed at both ends, and of a pale yellowish-white colour. It weighed 141½ grs., and measured 1 3/5 in. by ⅘ in. broad, with a circumference of 2½ in. to 3 in. Mr. Carver remarked upon the large size of the calculus, it being one of the largest ever recorded. These calculi were not uncommonly found in the ducts of the sublingual and submaxillary glands, but were rare in Steno's duct. The severity of the symptoms was by no means commensurate with the size of the calculus, in many cases great swelling of the glands and surrounding irritation being caused by a very small concretion.

Retro-uterine Hæmatocele.—Dr. BRADBURY read the notes of Charlotte C., aged twenty-eight, married, admitted into Addenbrooke's Hospital on May 13th. All her sisters suffer from excessive menstrual periods as well as herself. She was quite well till marriage nine years ago, but nine weeks afterwards miscarried, and was laid up for some time. She subsequently had several miscarriages, with pain and hæmorrhage, and bore one child at full term, but suffered from post-partum hæmorrhage. The history of the present illness was that she went ten days beyond the time for her menstrual period, and then had severe bearing-down pain, followed by profuse hæmorrhage and sickness. She became blanched, with sinking pulse, faintness, and noises in the ears. Vaginal examination showed the os uteri to be more open than normal. The abdomen was distended and tender, and the patient was unable to micturate, and kept her legs drawn up. After a time the distension gradually subsided, allowing a swelling to be felt just below the umbilicus, tender to the touch, fairly resonant all over except in left iliac fossa, and friction could be heard over it. The bladder contained three ounces of urine. Per vaginam, the uterus was pushed close under the symphysis pubis, and Douglas's pouch was distended by a soft doughy mass. On June 8th she passed a quantity of blood by the bowel; soon after the tumour began to subside. On the 19th she had a slight attack of pleurisy, but continued to improve in every other respect. On July 24th the swelling in Douglas's pouch had disappeared, leaving the uterus anteverted and more fixed than natural. On Aug. 15th she was discharged, being almost well. The temperature chart during the first three weeks showed an evenng rise to about 102°, and morning between 99° and 100°, for the rest of the time being slightly above the normal. Dr. BRADBURY remarked that this was a well-marked case of pelvic hæmatocele in a hæmorrhagic subject. Was it due to abortion, or had the menstrual period been delayed? There was at first no swelling to be felt in Douglas's pouch; the blood afterwards gravitated there and formed a tumour. The symptoms were very like those of parametritis, but the passage of blood per rectum and the diminution of the swelling cleared up the diagnosis. The treatment was rest in bed, and a hypodermic injection of one-sixth of a grain of morphia when the patient was suffering from the effects of the hæmorrhage, which proved very effective.

Tubercular Meningitis following soon after a Blow on the Head.—Mr. MARTEN was able, through the kindness of Dr. MacAlister, under whose care the patient was placed, to bring forward the case of a boy aged seven, who previous to his fatal illness had appeared to be enjoying fairly good health, with the exception of slight discharge from both ears, which had persisted for some months. His head was knocked against a wall on Dec. 10th, and from this date he was unable to attend school, suffering from sickness and persistent headache. He continued to go about till the morning of the 20th, and was then found by his mother totally unconscious. He remained in the same condition till the 22nd, when it was noted that he was perfectly unconscious, the pupils equal and reacting to light, the breathing quick and shallow, pulse small but regular, lips covered with sordes, tongue thickly coated, abdomen much retracted, tâche cerebrale very marked, and all the limbs quite stiff. He continued in the same unconscious condition, and died ten days after the blow was received. The mother, one brother, and sister had died of phthisis. The post-mortem showed the body to be well nourished; no evidences of any injury. On removal of the skull-cap the convolutions of the brain were found to be much flattened, and a few tubercles were seen scattered about its base and up the Sylvian fissures, with obvious meningeal inflammation around. There was a marked excess of fluid in the ventricles, and a dilated foramen of Munro. The lungs were studded with tubercles, especially at the apices. The kidneys showed caseous deposits in the pyramids and some pyelitis. There was no evidence of extension of the inflammation from the tympanum. Mr. Marten said the case was of interest from a medico-legal point of view, as it was difficult to determine to what extent the blow was the cause of death. Fortunately the meningitis proved to be tubercular, and a verdict of death from natural causes was returned.

Digitized by Google

Exostosis of Great Toe.—Mr. WALLIS showed this specimen, removed from a woman aged thirty-three. It had been growing for fifteen years, and had caused great pain. The whole of the last phalanx was removed. The growth sprung from the knotty terminal part of the phalanx, and not the epiphysis, and was covered with cartilage.

MIDLAND MEDICAL SOCIETY.

A MEETING of the above Society was held on Wednesday, Feb. 3rd, the President, Dr. Holmes JOY, in the chair.

Healed Phthisical Cavity.—Dr. FOXWELL showed a case of Healed Phthisical Cavity in a man who had been in the General Hospital under his care for repeated hæmoptysis, continuous pyrexia, and considerable excavation at the right apex some months previously, and who had now for two months done his work as a commercial traveller's porter. At present there were no signs by which the existence of a cavity could with certainty be diagnosed, owing to the amount of fibrotic contraction, nor was there any indication of progressive disease.

Anæsthesia of Hand. — Dr. SUCKLING showed a man who had been under his care suffering from complete Anæsthesia of the Left Hand. Ten months previously, in lifting an 18-gallon can of milk with a fellow porter, his assistant dropped the can, and the patient suffered a severe strain of the arm; anæsthesia and paresis of the hand immediately followed. There was no trophic or electrical change, and the only symptom that might have indicated actual injury to the roots of the brachial plexus was a slight dilatation of the left pupil, which might have been due to irritation of the root of the first dorsal nerve. Dr. Suckling concluded that the case was one of functional hyperæsthesia, and probably due to hypochondriasis, the man seeming depressed. The functional nature of the affection was proved by his rapid recovery after faradisation, and by the fact that if, when blindfolded, a mark was made some distance below the line where he said he could feel, when the bandage was taken off, he always felt down to this mark, so that a daily diminution of the area of anæsthesia was produced by deceiving him in this manner.

Antipyrin. — Dr. SAUNDBY exhibited the temperature charts of two cases of pneumonia and two cases of enteric fever created by Antipyrin. The temperature had been taken simultaneously in the rectum and axilla, and the result showed that the curves were almost completely parallel. Exceptionally, a slight fall in the axilla was accompanied by no fall or even a slight rise in the rectum, but the general course of the temperature was the same in both places. The observations were made in some cases every hour, in others every two hours. Dr. Saundby referred to a paragraph in THE LANCET where Professor Jaccoud was made to assert his disbelief in the utility of antipyrin, on the ground of its heat-reducing effect being solely peripheral, the rectal temperature remaining the same, or even rising, while the axillary temperature fell. He believed these charts disproved that assertion, and were evidence of the powerful antipyretic effects of this drug.

Flat-foot.—Mr. BARLING showed a youth on whom he had operated for Flat-foot. The deformity had arisen after acute rheumatism three years previously, and was of the most severe kind, especially on the right side. The left foot was treated by forcible manipulation, the right by Ogston's operation, as the enlargement of the tubercle of the right scaphoid prevented restoration of the arch until it was mostly removed. The arch of each foot is now excellent as far as appearances go, and the patient can walk some miles without distress; but although there appears to be bony ankylosis on the right side, yet that is, from the patient's statement, the weaker foot. It is important, however, to remember that it was the worst before treatment.

A meeting was also held on Wednesday, Feb. 17th.

Cyst of Parovarium.—Mr. TAYLOR showed a Papillomatous Cyst of the Parovarium which had been successfully removed by abdominal section. The patient was also suffering from uterine myoma and protrusion of the cervix uteri from the vaginal orifice. Since the operation no protrusion has occurred, showing that this was due in great measure to the weight of the tumour which was removed. Twisting of the pedicle and the rapid development of a blood-cyst below the original tumour occurred shortly before operation, and the case forms a good example of those complicated ones which almost defy classification. The appendages on both sides were removed. Mr. Taylor also showed a specimen and drawings of multiple minute cysts or vesicles of the broad ligament from a case operated on by Mr. Tait. This was a very rare condition, and he did not believe that any similar case had been described. He thought it possible that the case might be one of herpes of the broad ligament.

Hemilateral Myelitis.—Dr. SUCKLING showed a man who had been under his care for Acute Hemilateral Myelitis due to Syphilis. The patient was now able to walk, but complained of weakness of the left leg and of numbness of the right. Dr. Suckling had carefully investigated the muscular sense, and found that it was defective on the side of the lesion, the patient being able to distinguish between half-ounce and quarter-ounce weights on the right side, but not on the left. In this case Brown Séquard's dictum, which Dr. Ferrier had recently opposed, was confirmed. The case had been fully reported in the *Birmingham Medical Review* for August, 1885.

Mr. CHAVASSE showed the Stomach and Œsophagus from a case of Gastrostomy; a Vesical Calculus, weighing 5½ oz., that he had successfully removed from a man aged twenty-one by lateral lithotomy; and half an Inferior Maxilla from which a spindle-celled sarcoma was growing: this was removed from a man aged forty. During the operation the larynx became blocked with thickened mucoid discharge, and tracheotomy was performed to relieve the dyspnœa. The patient at the present time is doing well.

Mr. WALTER FOWLER showed a youth on whom he had performed a partial excision of the wrist for disease.

Dr. FOXWELL read a paper on Acute Laryngitis in Children.

Reviews and Notices of Books.

THE literature of bacteriology grows apace, for the very nature of the subject is favourable to many extravagant theories, as well as much imperfect observation. The essays and monographs which form the subject of this notice are, indeed, of most unequal merit, but they illustrate fairly well some of the facts and fallacies that surround the question. Thus Hoffmann's *brochure* (1) is written to establish a fact, hitherto denied by the majority of competent observers, that normal human blood contains an abundant quantity of micro-organisms, which under appropriate conditions may assume pathogenic properties. Where

Digitized by Google

others see only "granular matter" the writer sees living cocci and bacteria, and is clearly of opinion that the species may be transmuted, and even developed, into higher forms of fungi altogether. The two works of Dr. Zopf (2 and 3), dealing respectively with the bacteria and the mycetozoa, are of a different class. Forming contributions to the "Encyclopædie der Naturwissenschaften," they comprise a valuable systematic synopsis of these lowly forms of vegetable life, and are treated on a strictly botanical plan. To take the work dealing with the schizomycetes (spaltpilze) as an example: It opens with chapters upon morphology, on spore production and zoogloea formation, on physiology, including the nutrition of these organisms, their action upon surrounding media, and the influence upon them of physical and chemical agents; then the methods for their investigation are described; and, finally, the characters of each species are fully detailed. It may be interesting to quote the classification adopted. Ord. 1: Coccaceæ. Gen.: Streptococcus, Merismopedia, Sarcina, Micrococcus, Ascococcus. Ord. 2: Bacteriaceæ. Gen.: Bacterium, Spirillum, Leuconostoc, Bacillus, Vibrio, Clostridium. Ord. 3: Leptotricheæ. Gen.: Crinothrix, Beggiatoa, Phragmidiothrix, Leptothrix. Ord. 4: Cladotricheæ. Gen.: Cladothrix. Dr. Zopf is admitted as an authority on the subject, and he has certainly done much to systematise the knowledge hitherto gained upon the great variety of these minute forms of life, many of which play a large part in the etiology of disease. To pass from such writings to the rather voluminous book of Dr. Vogel (4) is to leave the firm ground of science to enter upon the most treacherous and insecure footing of speculation. The intention of the writer has been the praiseworthy one to harmonise the processes of disease with those observed in fermentation outside the body; but every page is full of the most extraordinary propositions and extravagant theories. He seems to believe that the bacterial groups are directly derived from the higher fungi, and describes and figures from various morbid secretions and products forms and structures the like of which have not, we venture to think, been met with before. It is inevitable, we fear, that the zymotic theory should lead to such absolutely erroneous work; but we could hardly have deemed it possible that any competent microscopist could have seen the things here described, or having seen them could have drawn such conclusions from his observations.

The lectures of Dr. Artiglas (5) were delivered in the Bordeaux Faculty of Medicine. They do not contain much that is novel, but are fairly accurate in the descriptions they contain of the recent work upon tuberculosis and pneumonia. For these two subjects occupy the major part of the book; one lecture, also, being devoted to actinomycosis, and a few others to generalities upon microbes, their investigation and relation to infective diseases. The bacillus tuberculosis of Koch is regarded as the same organism as the coccus described by Toussaint and the zoogloea of Malassez and Vignal—a variable morphology being not considered at all opposed to general conceptions of bacterial growth. It is asserted, also, that the pneumonococcus appears under various forms, and a contrast is drawn between the action upon the human organism of the tubercular microbe and the pneumonic. The subject of the nature of pneumonia, which precedes a description of its special microbe introduces the reader to the now well-worn historical facts pertaining to the epidemic occurrence and contagious manifestation of the disease. We cannot say that the lectures are profound, or that they are original; whilst some of the illustrations of apparatus, &c., might certainly have been more artistically rendered.

Far more satisfactory is the compilation of Dr. Mittenzweig (6), which comprises within a limited compass most of the essential facts concerning the pathogenic bacteria. There are chapters upon morphology, cultivation, inoculation, and the relation of bacteria to disease. It is pointed out that Naegele and Zopf are the chief supporters of the view of the mutability of species; Koch of their constancy; whilst Buchner holds a position on this question midway between the two opposing camps. The writer thinks that Koch's view is the most feasible; whereas, as we all know, many ingenious arguments to the contrary have been based on the occurrence of transitional and mixed types of specific disease. A clear distinction is drawn between the saprophytic and pathogenic bacteria; and the mode of operation of the latter upon the body is also well stated—viz., the general disturbance produced by ptomaines and the local disorders—as in erysipelas and diphtheria, typhoid fever, and tuberculosis, set up by the actual growth of the micro-organism. Sanitation and treatment based on the bacterial hypothesis are also discussed, and a brief description is given of each of the proved pathogenic organisms, a somewhat disproportionate allowance being accorded to the subject of cholera.

It is somewhat difficult to assign its proper value to the bulky and elaborately illustrated work of Dr. Domingo Freire (7). It constitutes a report to the Government of Brazil, and merits much praise for the evidence given of much patient and diligent labour in the endeavour to solve the problem of yellow fever, and suggest measures for its prophylaxis. Dr. Freire claims to have discovered the cause of this terribly fatal disease, and to have established a means of preventive inoculation. The discovery requires, however, to be verified, and, if we may judge from the evidence in its support adduced in the pages of this work, we should fear that the verification will be lacking. For in spite of the numerous descriptions and frequent illustrations given of the "cryptococcus xanthogenicus," it is difficult to see in it any very striking or distinctive characters. It is declared to occur in various stages of development, and to form cellular bodies containing pigment and spores, to multiply with great rapidity, and to be detected in large numbers in the blood and tissues, in the substance of organs, in the black vomit of the disease, in the bile, and in the urine. In this ubiquity it may claim to rank higher than any known pathogenic organism. It is aerobic and lives at the expense of the blood-globules and albuminoids of the body. Again, the cultures which Dr. Freire produced in milk, broth, gelatine, potato, and earth, are described as forming black masses, which certainly have characters not resembling the cultivations of any other known microbe. Its inoculation into animals is followed by rapidly fatal results and a reproduction of the micro-organism in the animal's body; and it is found in large amount in the hospital wards devoted to yellow fever cases and in the earth of the burying-grounds that receive the bodies of those who have died of the disease. All this and more is stated, so that the reader may be persuaded that the discovery is a reality; and yet there is, it seems to us, a lack of the precision of statement and clear definite enunciation of fact which are so necessary in establishing the truth of a question of this kind. However, acting upon the facts he has obtained, Dr. Freire obtained permission to practise preventive inoculations by means of the attenuated virus; and he not only details his method, but gives a list of the persons of all nationalities who were subjected to the practice. Certainly they show a remarkable immunity from the disease to which they were exposed during the epidemic of 1883-84; but in spite of these facts, it is better to withhold judgment until, as we have said, the facts and conclusions can be controlled and verified by other authorities. The volume is also rich in details of the pathological anatomy of yellow fever and of some of its clinical phenomena, and had it been written in a less diffuse style

Digitized by Google

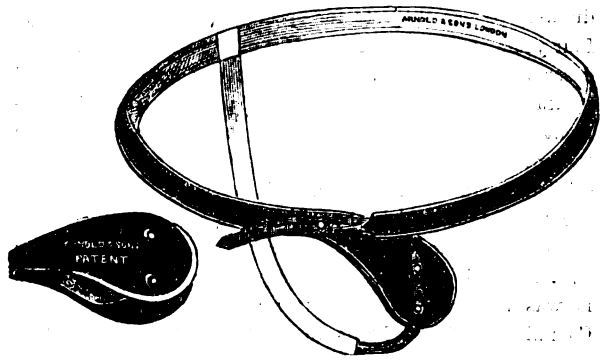
it would be an even more valuable contribution to literature than it is.

Dr. Nepveu's *brochure* (8) is a reprint of a paper written in 1870, and the object of its republication has doubtless been to show that more than ten years before Fehleisen's discovery, Nepveu had observed bacteria in the blood in erysipelas. The paper consists of a brief account of the examination of the blood in a few cases of this disease, the organism being described as the *bacterium punctum* of Ehrenberg; it was found in greatest abundance in blood drawn from the vicinity of the cutaneous inflammation.

Dr. Denucé (9) reviews at length the pathological anatomy of erysipelas in a manner which shows much diligence in historical and literary research, as well as evidence of skill in personal observation. Briefly he confirms the facts obtained by Fehleisen—viz., that the organism of erysipelas is a *streptococcus* which occurs in groups in the dermal connective tissue spaces, in the lymphatics, and in the subcutaneous tissue. He reminds us that its specific nature has been proved by the crucial test of human inoculation; in one case (inoculated by Jariche) of cancer of the breast the experiment was unfortunately fatal. Proofs are given that the secondary lesions of erysipelas may be assigned to the invasion of the blood by the micro-organism.

The Anatomy of the Intestinal Canal and Peritoneum in Man. By FREDERICK TREVES, F.R.C.S., Hunterian Professor at the Royal College of Surgeons of England, Surgeon to and Lecturer on Anatomy at the London Hospital. London: H. K. Lewis. 1885.

THIS is a reprint of Mr. Treves' Hunterian Lectures delivered at the Royal College of Surgeons last year, and which have already been published in another form. The lectures are founded upon the result of the careful examination of 100 consecutive subjects undertaken before any changes from decomposition had occurred, compared in many instances with the conditions found in some of the lower animals. Mr. Treves has succeeded in elucidating some obscure points; such, for instance, as the fossa duodeno-jejunalis, its formation and its relation to retro-peritoneal hernia, and mesenteric holes and mesenteric herniæ. The point, perhaps, of most immediate surgical interest is the demonstration that, contrary to the usual teaching of text-books, a meso-colon is more common on the left than the right side in the proportion respectively of 36 and 26 per cent. There is therefore more danger of opening the peritoneum in performing lumbar colotomy on the left side than on the right. Where, however, the disease for which the operation is indicated is undoubtedly seated in the rectum or sigmoid flexure, the operation will continue to be done on the left side rather than the right, so as not to interfere with the function of a greater length of the intestine than is necessary. For the future, however, surgeons will be less fearful of right lumbar colotomy in all cases in which it is clearly indicated, or in which there is a doubt whether a fistulous opening on the left side would meet the requirements of the case. We could wish that these useful lectures had been published in a more convenient form. The quarto size is not suitable for a modern library and for a book of such small dimensions. Rough-edged parchment paper is picturesque, but not convenient to turn over; and it is a great convenience to the reader to have the illustrations, which, in this case, are of great value in explaining the text, intercalated in the text rather than bound up at the end. The illustrations are also rather more roughly executed than is customary in English scientific works.



Minutes of the General Medical Council, of its Executive and Dental Committees, and of its Branch Councils for 1885. Vol. 22. London: Spottiswoode and Co., Grace-church-street, E.C.

THIS volume of the Minutes of the Medical Council is one of more than usual interest. Besides the resolutions of the Medical Council relative to the erasure of the names of several practitioners from the Register and the revision of the recommendations of the Council, it contains very interesting tabular statements as to the visitation of examinations and the various results of the investigations by the Statistical Committee. The seventeen tables included in these investigations are of very great value; they contain information of the time, places, and results of medical study, and of the ratio of medical practitioners to population, which it would be impossible to meet with elsewhere, and which cannot be too deeply studied by all who are interested in the profession, whether in its educational aspects or in its relation to the public wants.

New Inventions.

TRUSS WITH GLYCERINE PAD.

THE new truss for which letters patent have been granted to Messrs. Arnold and Sons, of West Smithfield, appears to be a great improvement on existing trusses. The pad is made of indiarubber and filled with glycerine, which is found after frequent trials and long experience not to

evaporate or escape, always remaining soft and comfortable, and has sufficient resistance to overcome ordinary forms of hernia. The pad, from its peculiar construction, adapts itself better than any other, as it completely closes the external ring without the possibility of enlarging it.

THE COMPOSITION OF HOPEINE.

To the Editor of THE LANCET.

SIR,—A good deal of obloquy having fallen upon the pharmaceutical trade in England in the eyes of our French neighbours, it would be as well if some explanation of the alleged facts in the above matter were afforded. In the *Nouveaux Remèdes* for February, Dr. Bardet, to quote an article in the *Pharmaceutical Journal* for Feb. 13th, "does not hesitate to say that if a fraud has not been practised, as he is inclined to think, it is at least incumbent on Dr. Williamson, as the discoverer of the alkaloid in the hop, to demonstrate the fact of its existence in that plant, and to clear up more thoroughly the remarkable resemblance between hopeine and morphine." It appears that Dr. Bardet purchased at a high price some so-called hopeine of some English manufacturing firms, and on testing the specimens could not find any distinction between them and morphine. M. Petit obtained the same result with other specimens. The language used across the water about this is, to say the least of it, expressive. We learn from the same article in the *Pharmaceutical Journal* that samples of the new alkaloid have been obtained and are now undergoing analysis at the Pharmaceutical Society's laboratory. As this was some weeks ago, by this time some results must have been obtained, and these results ought in justice to be given to the professional public. It is not a nice thing to think about that such an accusation should hang over our manufacturing pharmacists, on whom we as medical men are accustomed to fully rely, without any explanation. Trusting you will not allow this matter to be hushed up. Yours truly,

March 4th, 1886. SEISMOS.

THE LANCET.

LONDON: SATURDAY, MARCH 13, 1886.

ON Tuesday next in the House of Commons, Mr. STANSFELD will call attention to the Contagious Diseases Acts of 1866 and 1869, and will move, "That, in the opinion of this House, the Contagious Diseases Acts, 1866–1869, ought to be repealed." The whole history of these Acts, from their passing to the present time, has been so fully given in recent issues of THE LANCET, and the question is now reduced to so fine a point, that it is only necessary to recapitulate a few facts, and to show what will be the effects should Mr. STANSFELD'S motion be carried. The question to be decided is, are prostitution and venereal diseases proper subjects for special legislation? Twenty-four years ago a Select Committee of the House of Commons described the state of prostitution at our home, naval, and military stations as "appalling," and pressed on the Government of that day the necessity of at once grappling with the mass of vice, filth, and disease which surrounded the soldiers' barracks and the seamen's homes. The result was the Act of 1864, which, though causing a great reduction of disease, was found to be insufficient, and, after an inquiry by a medical committee extending over nearly two years it was replaced by Mr. CHILDERS' Act of 1866. Select Committees of the Lords in 1868 and Commons in 1869 reported so favourably of this Act and its results that it was followed by the Act of 1869, which considerably enlarged the sphere of its operations and improved the former one in several details. Then arose the opposition to these Acts, which has continued ever since, and an attempt to repeal them in 1870 was defeated by a large majority, the matter being referred to a Royal Commission. The Royal Commissioners, while recommending certain changes, one of which was that the compulsory examinations of women should be discontinued, reported favourably of the Acts, and strongly urged their maintenance. "We attach," they say, "great importance to the maintenance of a system which, if it cannot altogether annul, may at least materially mitigate, a pestilence which is not, like other contagions, of occasional occurrence, but one of perennial growth. The offenders who bring this affliction upon themselves by their own vicious indulgence may have no claim to the compassionate care of the State, but the numerous innocent persons who suffer from the disease are surely entitled to consideration." We venture to express our hope, therefore, that while due consideration is paid to the sentiments of the people in regard to prostitution, no misapprehension as to the real moral bearings of the question, and no want of courage, will be suffered to prevent the application of such remedy as may be practicable to this great evil. The firmness of a former Parliament withstood the storm of clamour with which the discovery of vaccination was assailed by the ignorance and prejudice of the day, and relieved posterity from a scourge which was the terror of earlier generations; and we would fain hope that an attempt to stay the progress of a plague scarcely less formidable in its ravages is not to be hastily abandoned.

In 1871 a memorial in favour of the Acts was signed by 2500 medical practitioners, including, with very few exceptions, all the leading physicians and surgeons, and presented to Lord ABERDARE, then Mr. BRUCE, Home Secretary. Motions for the repeal of the Acts were brought forward in 1873, 1875, and 1876, and defeated by large majorities; in 1878 a similar motion was "talked out," and in 1879 it was met and defeated by the previous question being carried. In the last-mentioned year a Select Committee of the House of Commons was appointed to inquire into the Acts, and whether they should be maintained, amended, extended, or repealed. After an inquiry extending over four years, they reported that the Acts had successfully served the two objects to which they were directed — the diminution of venereal disease and the increased efficiency of the army. In discussing the question of repeal they report:—

"But apart from this consideration, it is most important that Parliament and the country should clearly understand what the simple and absolute repeal of the Acts, including the abolition of police surveillance and of State-aided lock hospitals, would mean in districts where they have been in operation for thirteen years and more. It would mean: (*a*) Full licence for venereal disease of all kinds to disseminate itself, unchecked either by police control or by hospital treatment. (*b*) A serious diminution in the effective strength of our army and navy, which would be especially felt in the event of their services being suddenly called into requisition. (*c*) The relegation of numbers of these unhappy women to the state of hopeless misery, squalor, and disease in which they lived before the system was introduced. (*d*) The letting loose of increased crowds of abandoned and diseased women and girls of all ages upon streets and thoroughfares swarming with soldiers and sailors, with little or no practical check or control over their behaviour. It is scarcely surprising that such a prospect should excite feelings of dismay in the minds of the more intelligent and thoughtful inhabitants of subjected districts."

In 1883 the compulsory examinations of women were abandoned in consequence of a resolution of Mr. STANSFELD to that effect having been carried by what is generally admitted to have been a snatch vote. In consequence of this, the number of admissions into the Government hospitals for females has fallen off 50 per cent., there has been a great increase of disease among both soldiers and seamen, and, in short, all the evils enumerated above have occurred, with this modification—viz., that those women who voluntarily apply at the lock hospitals are admitted and detained there until cured. Should Mr. STANSFELD'S resolution be carried on Tuesday, even this moderate and humane arrangement will have to be abandoned, for without the sanction of Parliament no funds can be obtained wherewith to carry on the lock hospitals, all or any of them, for a single day. It is most important that members of the House of Commons should be well aware of the effect of their votes. All the preceding facts can be verified by reference to the reports indicated, and do not admit either of dispute or modification. It is not now a question of compulsory examinations or of police control, or compulsory admission into hospital. It is a question of common humanity, Are the Government lock

Digitized by Google

hospitals to be all closed, the unfortunate prostitutes who are now in them to be driven into the streets uncured, and all who may in future apply for admission to be denied? This is the question which each member must ask himself, for on the answer depends whether he will vote for or against Mr. STANSFELD'S motion.

THERE are few practitioners among the middle or upper classes who are not called upon from time to time to advise a consumptive patient regarding the choice of a sanatorium where he may seek restoration to health, or at least escape the gloom and damp of the English winter. The choice is one of the most delicate problems which present themselves to the physician, inasmuch as it involves not only a thoroughly correct estimate of the constitutional peculiarities of the patient and the type of his malady, but also a knowledge of foreign countries, which few have the opportunity of acquiring by travel and personal observation. We think we shall be doing a service to the profession by endeavouring to disseminate a knowledge of some general principles on this question which may now be regarded as almost universally accepted.

First of all, there are many cases where the resort to foreign travel should be resolutely forbidden. Nothing casts greater discredit upon the profession or is more injurious to individual careers than the indiscriminate ordering abroad of all consumptives. Many a one, who might at least have enjoyed a peaceful *euthanasia* amid the comforts of home and surrounded by familiar and sympathetic faces, is cast overboard as a corpse by strange hands, or dies miserably in a foreign lodging-house. Where the malady is far advanced and steadily progressive, where wasting is a very prominent symptom, where there is persistent pyrexia unrelieved by remedies, or where ulceration of the bowels exists, foreign travel is usually quite unavailing, and cannot be honestly recommended. It ought to be very strongly laid down that travel is not admissible as a *dernier ressort*. If reasonable hope of benefit does not exist, it is cruel and culpable to advise a measure which is never indifferent, but either promotes recovery or accelerates the fatal issue. We speak thus strongly not from any want of faith in climatic treatment—of the enormous value of which, when rightly directed, no one can be more profoundly convinced than ourselves,—but because we are keenly conscious of the lamentable discredit which one case of obvious and avoidable failure casts upon an important and hopeful branch of therapeutics.

Having decided that our patient is in a fit state for foreign travel, we have to approach the more difficult question of the selection of a suitable resort. If the patient retains a fair amount of vigour, if free from general bronchitis, cardiac or renal disease, severe digestive disturbance, and serious nervous debility, we think there can be little doubt that the high altitude treatment, as pursued at Davos, St. Moritz, and Samaden in Switzerland, Bogota in the Andes, Manitou springs in Colorado, and elsewhere, affords by far the best prospect of success. Much wasting or persistent pyrexia are, *pro tanto*, contra-indications to this line of treatment, but the essential indication for its adoption is the retention of a fair amount of circulatory and digestive vigour. The patient who has decided to have recourse to the mountains should observe two precautions: first, he should make the journey in two or three stages, so as to become gradually habituated to the novel atmospheric conditions prevailing at high altitudes; and secondly, if he selects a resort where frost and snow prevail, he should remove thither at the end of summer or beginning of autumn, instead of waiting for the advent of winter, in order that he may learn to bear the strain of the aerial rarefaction before being called to add thereto the strain of intense cold. The high altitude treatment has the great advantage of tempting to vigorous out-door exercise and amusement, and thus gradually lures the patient to relinquish his habits of invalidism, which in warm and sedative climates he only learns to hug the more closely. We are still much in need of satisfactory statistics to show beyond cavil the results of treatment at the high stations, but there can be no doubt that much good has been thus effected, and that this line of practice is steadily advancing alike in professional and in public favour.

Of the lowland resorts there are two types—the marine (such as Cannes, Algiers, Malaga, or Madeira) and the inland (such as Cairo, Assouan, Bloemfontein, or the riverine towns of New South Wales). Warmth prevails alike in both, but in the former case we have warmth *plus* humidity, in the latter warmth *plus* a high degree of dryness. Yet individuals vary so much, and the climate of any locality is such an infinitely complex factor, that it is extremely difficult to lay down any rules, even approximately. Some specific indications and contra-indications, however, exist, and it is highly desirable that they should become more widely known. Thus the presence of nervous disturbance—hysteria, neuralgia, sleeplessness—should be an absolute bar to Cannes or Nice; hepatic troubles preclude recourse to Algiers; intestinal derangement is a sign-post that Madeira must be avoided, as there diarrhœa is so prevalent as to be known as the "island complaint." Writers on consumption lay down various rules regarding the sanatoria most adapted to different types of the disease, but those who have had the largest experience of foreign health-resorts will be the most ready to admit that prediction on this subject is still most difficult and uncertain, and that more seems to depend upon the constitutional condition of the patient, his idiosyncrasies of nervous, circulatory, and digestive organisation, than upon the type of his malady, regarding which rules are apt to be arbitrary and so beset by inevitable qualifications as to be practically useless.

Australia has long had a high repute for consumption—a repute which is thoroughly well founded, yet in much danger of being imperilled by ignorance or neglect of one or two fundamental principles. The parts of the great Australian continent suitable for phthisis are the great inland plains, where the climate is singularly dry and equable, intensely hot in summer, but agreeable at other seasons. The littoral is quite unsuited to consumptives, and few worse climates exist for such cases than Melbourne, where extreme and sudden changes of temperature, frequent dust-storms, and open sewers combine to produce a condition of things pernicious in the last degree to the phthisical sufferer. No wonder the Australian practitioners express their astonish-

Digitized by Google

ment as one shipload of consumptives after another disembarks and settles in Melbourne, there to lose in a few weeks the benefit usually acquired on shipboard and soon to sink into a premature grave. Such patients should not lose a day in departing for the interior, or they may safely cross Bass's Straits and settle in the charming and healthful island of Tasmania.

The Cape is not so popular now as in its palmy days, when it was the half-way house to our great Eastern dependency. Cape Town is all that it should not be in a sanitary sense, and frequent epidemics have from time to time scourged its inhabitants for their neglect of Nature's laws. The suburbs are charming, and possess reasonable accommodation; but the climate is somewhat treacherous, and storms are frequent. The climate of the interior is more equable, and in the main healthful, whilst means of transit and accommodation of all kinds are becoming less primitive and trying to invalids.

One last word regarding health-resorts for phthisis. When the patient has found one to suit him, let him remain there, and neither return home nor rove beyond it; neglect of this rule has brought many a young life to a too early extinction.

THE state of the central nervous system in sleep is a fertile subject for discussion, replete with interest, full of uncertainty, and possessing as much bearing on the welfare of the human race as any other subject that could be named. The cerebral cortex is during healthy sleep in a state of functional inactivity; its nutritive processes are unknown, though it is conjectured that ascending metabolism is at its maximum and descending at its minimum—exactly the reverse of the waking state. What degree of sleep occurs in the nervous centres that lie below the level of the cerebral cortex is also an unknown quantity. During the waking state it is the function of the cerebral cortex to spontaneously originate functions, just as it is for the heart to go on beating or the breathing to continue its undulations. Many of the lower nervous centres during sleep are in a condition of over-activity; this over-activity is not ordinarily manifest, because these lower centres only act as the result of some recognisable excitant. Being such an extensive system and possessing functions so diverse, different parts of the central nervous system may be in very different conditions at one and the same time. The bulk of the cerebral cortex may be inactive whilst some of the centres are still in partial action. We say partial action, because it is probable that complete functional activity of a cortical centre is impossible unless the whole of this region is sensitive. This is the only kind of way in which scientific physiologists can interpret the phenomena of somnambulism, dreaming, ecstasy, and the like. An interesting contribution to the subject has recently appeared from the pen of Dr. LYMAN.[1] "Natural sleep is that condition of physiological repose in which the molecular movements of the brain are no longer fully and clearly projected upon the field of consciousness." This is Dr. LYMAN'S definition. We cannot acquiesce in the statement. We would grant that it is a question of molecular movements, but then it is not said what sort of molecular motion. Clearly during sleep we have two opposite conditions. There is no doubt that functional activity of the brain ceases; in other words, there is loss of consciousness. How incomplete, then, is a definition that asserts that molecular movements are no longer fully and clearly projected upon the field of consciousness. It had better be said that there is no field of consciousness on which molecular movements can be projected. Physiologically, consciousness itself must be regarded in its essence as a form of molecular motion; what it is psychologically we have no means of knowing. Again, the definition is, we believe, incorrect, because, though molecular motion that produces function is in abeyance, it is also indisputable that some molecular motion must be going on in order to regenerate and restore the nutrition of the brain. After a period of repose the brain is able to continue working for a very much longer time than would be possible (without deterioration) if it had previously been in action. It may be conceded that sleep may vary in depth but in health the degree of "dissolution" of the cerebral functions should be notified by the absolute abeyance of the highest functions of the brain. There should be no dreaming—no action, in other words, of the visual, auditory, or any other of the higher centres. In somnambulism, which also varies in extent as well as in depth, the phenomena are best explained, not on the assumption of a general depression or dissolution of function taking place equally and in all directions, but by continuance in action of certain tracts of the central and peripheral neuro-muscular system. In somnambulic lethargy, to which Dr. LYMAN devotes a section, we read that this condition represents the form that outwardly resembles profound sleep. In this condition there is a persistent loss of consciousness, and the sleepiness or functional inactivity is of great depth, so that the patient breathes but feebly, and the circulation is reduced to a low ebb; swallowing and other organic functions even participate in the reduction. The chapters on Dreams and Somnambulism and Artificial Somnambulism are well constructed, and contain a large amount of readable information; but the exigencies of our space preclude the further consideration of the subject at present.

[1] Insomnia and other Disorders of Sleep. London: Trübner and Co. 1885.

WHEN commenting on the subject of Lunacy Law Reform in our last issue, it was observed that, "as regards the 'private asylum question,' we think that may be hopefully left to adjust itself, under the influence of a provision that public authorities may—it ought to be *shall*—provide for private needs." The hope is, that when adequate accommodation has been provided for the care and cure of the insane of all social classes in public institutions, there will not be any considerable number of cases in which recourse is had to the private or licensed houses; and in a reasonable time, without any need for the ratepayer to dip his hands further into his pockets than he is at present, unhappily, compelled to dip them for lunacy purposes, private asylums, not being any longer profitable undertakings, will cease to exist. We go further, and hope and believe that the friends of the unsound in mind will for their own protection choose public and official guardians for their patients in preference to private and non-official custodians; so that after the new system comes fully into operation, the bare fact of

Digitized by Google

desiring to place an alleged lunatic in a private house would give a *primâ facie* appearance of desire for a hole-and-corner procedure in preference to the open-handed way of sending the insane at once in the broad light of day to a public institution.

Meanwhile, it is impossible to hide from view that the method proposed in the new Bill is neither a public-spirited nor a wholly satisfactory one. It is, in truth, an attempt to evade the expenditure of what may well be regarded as an equitable sum in purchase money for the existing asylums. The idea of the private asylum clause is to set up a rival business, conducted by public officials, which it is anticipated will more or less quickly ruin the business of the existing proprietors and lessees of private asylums by drawing away their customers. It would, of course, be far better to go into the market and buy the licensed houses at a fair price. The law has so long sanctioned the private asylum system that it is obviously sharp practice to try to supplant those who have invested money in this enterprise on the faith of a Government monopoly, instead of dealing with them on commercial principles. If, instead of buying up the goodwill and plant of the telegraph companies, the Government had started an opposition business in telegraphy, there would have been a loud and justifiable outcry. Yet this is what the Government proposes to do with regard to the private asylums. If the business of hotel- and lodging-house-keeping for the insane be a profitable enterprise, as we are compelled to believe it is, there can be little doubt that it will prove a paying business in the hands of the public authorities now in charge of county and borough asylums. They will make money by the venture, and the profits that accrue will be available for the reduction of the rates. The very great success of quasi-public institutions—such, for example, as St. Andrew's Hospital, near Northampton—is in itself conclusive as to the advantages which will be gained by grafting this private business on the public business of the local asylums. We have no doubt whatever as to the result. As soon as public asylums take paying patients these institutions will be generally preferred, not only for patients just above the rank of paupers, but for the well-to-do. It is therefore necessary to face the fact that a ruinous blow is being struck at the private asylum system by the measure now before Parliament. Meanwhile, as we have said, it is a foul blow in a commercial sense, and we must protest against it as unfair to the proprietors of, and investors in, licensed houses.

The proper course, beyond all doubt, is to buy up the existing properties; and this might, as we have suggested, be very well done by the creation of guaranteed stock bearing a fixed rate of interest, having a marketable value, and being readily transferable. It is not necessary to make any special call on the rate- or tax-payer. The stock issued, being guaranteed, might be made redeemable at the expiration of a reasonable period. This seems to us the best way of getting over the difficulty. The present conjuncture is not one at which it would be easily practicable to induce the Government or the Legislature to sanction the raising of a large capital sum to buy up the private asylums; but if these were taken over by the State, stock might be issued in payment of the purchase money, and each proprietor would then be able to hold or sell at pleasure, while the bonds, being guaranteed, would be negotiable at fair prices. On public grounds it is most desirable to expedite the substitution of public for private asylums; and if the course we suggest were adopted, there would be no insuperable obstacle to the completion of the necessary change within a few months, or one year at the utmost. When, or before, the Bill now in charge of the Lord Chancellor comes to be submitted to the House of Commons we venture to hope the suggestion we reproduce, and which has been so repeatedly urged in these columns, will receive the attention we think it demands and deserves.

Annotations.

"Ne quid nimis."

THE CEREMONY ON THE EMBANKMENT.

WE understand that His Grace the Archbishop of Canterbury will take part in the ceremony of the laying of the foundation-stone of the new Examination Hall of the Conjoined Colleges by Her Majesty the Queen, on March 24th, and also that the choir from the Chapel Royal, Savoy, are to attend. The details of the ceremony are not yet, we believe, completely elaborated, but we hope to be able to give next week full information as to the way in which it is to be carried out. It is long since the Sovereign has taken an active part on such an occasion; the honour, therefore, conferred on our profession is graciously and peculiarly a marked and flattering one, and we are confident that no efforts will be wanting to make the occasion not only a most notable red-letter day in the annals of English medicine, but that it may be also the means of leaving in these restless and unstable days in the memory of our Queen a pleasurable reminiscence of the loyalty and devotion of those of her subjects who are engaged in the honourable profession of medicine. We are glad to be able to add that there is every prospect that room will be found for the Members as well as the Fellows of the College of Physicians. The Fellows and the Members of the College of Surgeons, their number being so great, will have to abide by "the chance of the die." A very large majority of gentlemen who hold the licence of the College of Physicians are also Members of the College of Surgeons; these will accordingly have, at least, a chance of being present; there are, however, some few who have contented themselves with the L.R.C.P. Lond. May we venture to suggest that, especially as previously to the conjuncture of the two Colleges inducements were offered to them to consider this diploma a complete one, it would be a gracious act to give them some opportunity of being present on an occasion which cannot but afford them considerable and special interest.

MEDICAL REFORM.

THERE seems a disposition in some quarters to try to resuscitate the question of medical reform. No one can be more sensible than we are of the faults and defects of the present state of our medical examining bodies, and still more of the Medical Council, by which they are supposed to be governed and supervised. But we must express our strong opinion against any attempt to deal with these questions at the present moment. To expect any serious attention to be given to them in the present position of parties and of public affairs is to betray a sanguine disposition, which we at least do not possess. Any legislation in present circumstances would be unworthy of the name, and would leave the chief points of medical reform un-

Digitized by Google

touched. Even the introduction of a few direct representatives of the profession to the Medical Council may be dearly bought. And such would be the case if this one point were gained and every prospect of gaining other points were abandoned. The tension and rivalry of parties paralyse Parliament for dealing with such questions without disappointing all those who are earnest in wishing to see old institutions adapted to existing conditions. Sir Lyon Playfair is no doubt well acquainted with the essential points of medical reform. Further, he is no longer bound in a servile relation to one set of the institutions likely to be affected by legislation. Yet more, he may be credited with having long since escaped from the strange delusion that the overcrowded medical profession does not attract a sufficient number of men to fill the vacancies occasioned by death and other causes. But even so, he cannot manufacture time, or alter the fact that Parliament is absorbed with other questions.

THE AGMINATE AND SOLITARY GLANDS.

THE notion that atrophy even to total disappearance of the Peyerian and solitary glands of the intestine proceeds with advancing age bids fair to be dispelled by a painstaking research which we owe to Adolf Passow (Virch. *Archiv*, 101, Hft. 1). By aid of a very simply devised apparatus, Passow set himself to count the number of follicles and Peyer's patches in the intestine in subjects of all ages dying from various affections; he also calculated the total area occupied by the Peyer's patches, and reckoned the relative proportion this occupied to every 1000 square centimetres of the intestinal surface. He gives a table of forty-five cases so examined, and his calculations and method may best be gathered by citing, with necessary curtailment, one of the observations so tabulated:—"No. 27—a man aged thirty-six, much emaciated, died of phthisis; small intestine measured 789 centim. in length and 7 centim. (mean) in breadth; the highest Peyer's patch was met with at a distance of 140 centim. from the pylorus; number of patches 19; total superficies of patches, 61·85 sq. centim, or 11·29 per 1000 sq. centim. of intestine. There were 24·61 solitary follicles per 25 sq. centim. of intestine, giving a total of 5406 of these glands." In only one case, a female aged forty-nine, the subject of tabes, neither solitary nor agminate glands could be detected. In another case, a man aged twenty-six, there were only 0·5 follicles per 25 sq. centim., or a total of 123 in the whole of the small intestine. But such a small number was exceptional, for only six cases had fewer than 1000, the highest number being 8961 (or 76 per 25 sq. cm.), found in a girl nine years of age; whilst among adults the highest number occurred in a man aged sixty-one—viz., 5760 follicles (or 25·1 per 25 sq. cm.). As a rule the number of follicles increases from the pylorus downwards, but exceptionally the pyloric segment of the duodenum contains more than other portions of the bowel. As to Peyer's patches, variations in number and area occurred within wide limits—e.g., in one case the area occupied per 1000 sq. cm. of intestine was 18 sq. cm., in another 1·9 sq. cm. In one case there were only 6 patches, an infant of nine months; in another 41 patches, a woman of twenty-four years. An old man aged eighty-one presented 15 Peyer's patches, with relative area (per 1000 sq. cm.) of 15·8 sq. cm.; in the same subject there were 12·13 solitary follicles per 25 sq. cm. of intestine, or a total of 2377 well-marked though small glands. By calculating the average superficial dimensions of the intestine in adults and children, and the average proportionate number of solitary follicles, the interesting result appears that whereas the intestinal surface has in adults nearly four times the area that it has in children, the relative number of follicles is precisely reversed. Thus in adults the intestinal superficies averages 5582 sq. cm., in children 1513 sq. cm.—i.e., a ratio of 3·68 : 1; the number of follicles per 25 sq. cm. averages in adults 11·28, in children 45·11—i.e., a ratio of 1 : 4·09. But, on the other hand, there is no definite relation between the period of life in adults and the number or extent of these follicular glands; some of the greatest differences in these respects being seen between subjects of the same age, whilst a young man of twenty-six had no more than an old man of eighty-one. Nor was it found that any constant relationship occurred between the Peyerian glands and the solitary follicles; a deficiency in the one was not accompanied by an excess of the other. Briefly it would appear that these lymphatic structures attain their greatest development in childhood; that with the growth of the body they do not increase; but that remarkable variations occur with respect to their persistence, exceptional degrees of this warranting a belief in a "lymphatic constitution" of the affected subject finally, that total absence of them is phenomenal, but not unknown, and certainly not a necessary concomitant of old age.

BUTTERFLIES IN WINTER.

A TEDIOUS, protracted drive in a carriage on a wintry day, with a bitterly keen wind, and most insufficient clothing! Such were the conditions under which many young ladies, mere girls, by no means too hardily trained, made their *début* into society the other day by Royal introduction. Nor was the occasion much different in this respect from others of the same kind, or, indeed, from other gatherings of less pretentious kinds. Custom has been at work in the same way all through the winter, not at Buckingham Palace, but everywhere, fixing its yoke on every neck, fit or unfit, careless of climate, health, or any consequence—of almost everything, it would seem, except tradition. We will not say that reforms in the way of adaptation to season and sense have given us no sign of their advent. The low bodice—that model of classical and doubtful taste in dress, that tempter of disease too often successful—is giving place to forms of dress more rational and more safe. Hours of assembly are changing slowly, and it is coming to be questioned whether the cold small hours of the morning must be reached before the guests depart. Yet, withal, improvement is slow, and we can only look hopefully for the time when society in every rank, the higher and the lower, will recognise that even such pleasures, to afford the most refined enjoyment, do not demand quite so lavish a sacrifice of more sober considerations.

DEATH-RATE AND SANITATION IN RUSSIA.

A SERIES of admirable articles on vital statistics and the importance of sanitary measures is now appearing in one of the St. Petersburg daily papers, founded on a paper by Dr. Eck. The statistics given are certainly of a nature to set every one in Russia thinking seriously about taking measures to improve them. Thus for the year 1882, which seems to be the last year whose vital statistics are available, the mortality in the ten southern provinces was 2·6 per cent., in the seven eastern provinces 3·9 per cent., in the thirteen middle provinces 6·2 per cent., in the sixteen western provinces 3·1 per cent., and in the fourteen northern provinces 3·7 per cent. After mentioning the various sanitary improvements called for, as drainage of various kinds, a supply of wholesome drinking-water, attention to and regulations about buildings of all descriptions, and the establishment of infectious hospitals, Dr. Eck goes on to say: "There is no need for us to puzzle ourselves how these matters are to be done; England has accomplished so much that we need simply adapt what is ready to our hands to our own circumstances. In Germany, France, Austria, and Italy steps are already being taken in the same direction, and all these

Digitized by Google

countries take England as their chief model, so that we need not be ashamed to do so too." He then appeals to the economic importance to Russia of a reduction of the mortality. On the principle of example being better than precept, he goes into a long but easily comprehensible calculation of the comparative working value of horses whose ages at death vary; and he then takes the respective death-rates of Russia (35), Germany (27), and England (19), and, by means of a method of computation unusual amongst British statisticians, explains that they show that an Englishman has 53 years of life, while a German has 37, and a Russian 29 only. Reckoning a man's working years to commence at the age of 18, an Englishman has 35 years in which to earn against the Russian's 11, and the latter will probably not save much more in his 11 working years above what it costs him to live than has been already expended upon him during his 18 unproductive years; but an Englishman will have 24 years more in which to go on earning and saving. Again, out of 1000 inhabitants in Russia, only 373, or 37 per cent., are of an age to earn, while in England there are 660, or 66 per cent.; or each individual of working age in Russia has to provide for two non-workers, while in England he has only half a non-worker for whom to be responsible.

RATING OF HOSPITALS.

THE movement for the recognition of the rights of hospitals to continue to enjoy their old exemption from the payment of local and other rates continues. Its last manifestation was a conference of authorities of public charities held at Guy's Hospital on Saturday last under the presidency of the treasurer, Mr. Edward Lushington. There were present, among others, the Earl of Leven and Melville, the Hon. Tatton Egerton, M.P., Major Morgan, Mr. O. V. Morgan, M.P., Sir Henry Peek, Professor Leone Levi, Colonel Hamilton, M.P., and many other members of Parliament. Various resolutions were passed, including one pledging the meeting to support a Bill to be introduced into Parliament to restore the old exemption of public charities. The arguments on this subject, as regards hospitals, are certainly all on one side, and the very least the State can do in the present impecunious condition of these institutions is to pass the Bill. Hospitals save the money of the taxpayers both by providing for the poor when sick, and by hastening their restoration to health. All other countries endow their hospitals. The least we can do is not to tax our own.

ACTION UNDER THE CHOLERA ORDER IN THE PORT OF LIVERPOOL.

As many as 20,894 vessels entered the port of Liverpool in 1885, and of these 4078 were submitted to inspection, with the result that 205 were found to be in a defective sanitary condition. The German, Belgian, Dutch, Swedish, and Norwegian vessels are those which, belonging to foreign nations, are best kept; and the Liverpool owned vessels are, as a rule, in very good condition, and so also are most of the English ships. Indeed, the systematic inspection of vessels in English ports and the requirements of the port authorities are having a most beneficial influence on shipping entering our ports. Three vessels were during the year dealt with under the Cholera Order. The *Mayo* was from Carthagena, and a man sick of diarrhœa was on board; but after medical inspection the vessel was released. In a similar way the *Donati* from Barcelona was allowed to enter the port. The third was the *Cartagena*. After leaving Marseilles on August 8th, she started for Oran; but the whole crew, engineers and officers, becoming affected with diarrhœa, she had to put back, two of the crew dying on the return journey, and two others being received into the Marseilles hospital. On August 26th she sailed for Carthagena, and, having taken water and provisions on board, she left there on Sept. 11th. Two of the crew were taken ill on Sept. 13th, another could not work, and several members of the crew were from time to time attacked with diarrhœa and colic. On arrival at Liverpool fresh water and provisions were sent on board, two of the crew were received into the port hospital at New Ferry, and then the vessel was released. Dr. Taylor points out the fact that, as in the case of the *Saint Dunstan* in 1884, the diminution in the general prevalence of diarrhœa and uneasiness in the bowels and the rapid recovery of the sick were remarkable on the vessels being supplied with fresh water. The importation of small-pox from Canada by means of shipping also gave rise to much increased activity during the later months of the year, and a number of patients were received into the City small-pox hospital, the vessels undergoing disinfection.

THE COLD WEATHER AND THE DEATH-RATE.

THE last weekly return of the Registrar-General shows that during the week ending last Saturday the annual death-rate in the twenty-eight large English towns, having an estimated aggregate population of rather more than 9,000,000, was equal to 26·6 per 1000. In London the rate was 26·9, and in the twenty-seven provincial towns it was 26·2. Taking the last four weeks, in which the fatal effect of the recent cold weather has been most marked, the variations in the mean death-rates in the various towns have been very wide. While the mean rate in these four weeks was 24·6 in the twenty-eight towns, it was only 17·6 in Leicester, 18·7 in Hull, and 19·9 in Sheffield; whereas it ranged upwards in the other towns to 28·4 in Preston, 28·5 in Plymouth, 30·0 in Manchester, and 32·7 in Blackburn. The rate in London during the same four weeks was 25·6, and only slightly above the average in the twenty-eight towns. The cold weather during February, to which this great, though unequal, rise in the death-rate has been due, was quite exceptional. The mean temperature at the Royal Observatory, Greenwich, for the month was only 33·7° F., and 4·8° below the mean temperature for the month in 100 years. It is more than thirty years since we have experienced so cold a February; in 1853 the mean temperature of that month was 33·3°, and in the memorable frost of 1855 the month's temperature was so low as 29·4°. The recent death-rate, bearing in mind the low temperature, affords very favourable comparison with the rates that prevailed in the corresponding periods of several recent years in which the mean temperature was much higher. It is worthy of note that during the first nine weeks of this year the deaths referred to diseases of the respiratory organs in London have only exceeded the corrected average in the ten preceding years by 127; in the first six weeks of the year they were 446 below this average; while the excess in the three weeks ending last Saturday was 573.

THE ANATOMY OF THE LUNG.

THE capillary network of the pulmonary alveoli, the respiratory network, whose vessels are scarcely large enough to allow of the passage of the red blood-discs, and whose meshes are almost extinguished during congestion, forms an immense mantle of blood of the thickness of a red blood-corpuscle, and having a superficies, according to Küss, of 150 square metres, representing about two litres of blood. Not knowing by what method Küss had arrived at this estimate, M. Marc Sée has, by an elaborate calculation, endeavoured to ascertain for himself the correctness of Küss's assertion. A brief note in the *Union Médicale*, No. 27, describes the method Sée adopted, and also the result obtained, which was 130 to 135 square metres, or nearly the same as that of Küss.

SCOTTISH HOSPITALS AND THEIR MEANS OF SUPPORT.

A VERY instructive and thoughtful account of the work of the Scottish hospitals, and the way in which they are supported, appears in the *Glasgow Herald* of March 3rd. Like English hospitals, they suffer from impecuniosity; and the chief interest of the article is in its discussion of the ways in which the several items of income might be raised so as to balance the expenditure. Of the twenty-two general hospitals of Scotland four are endowed, so that only eighteen depend solely on voluntary subscriptions. In 1885 they treated 24,668 in-door patients and 118,538 out-door or dispensary cases. The ordinary expenditure was £115,616, or, applying the whole cost to in-door cases, £4 13*s.* 9*d.* for each patient, as against over £8 in English hospitals. The total *ordinary* income is £95,001, made up of the following items: interest from investments, £22,986; students' fees, £5612; payments for patients' board and treatment, £4014; total contributions and donations for maintenance (about 4*d.* per head of the entire population), £62,389. The *extraordinary* income, on the other hand, consisting principally of legacies and special donations, was £56,767, from which has to be deducted not only £18,156 of extraordinary expenditure, but the £20,615 deficit in the ordinary income and expenditure account. As to the ways in which this regular annual deficit is to be made up. The proposal to put hospitals as a burden on the rates is ably discussed and wisely rejected, as tending to pauperise the people, to dry up the springs of charity, and to fall most heavily on those classes of taxpayers least able to bear it. If any departure from the voluntary system is to be adopted, the writer would prefer a grant from the imperial exchequer, giving no impression to local feeling of a *right* to use the hospitals for common purposes. An extra penny on wine and spirits, he thinks, for this purpose would do no harm. But he holds that voluntary system has not failed, and that with a little more care and trouble it can be developed so as to raise contributions from subscribers, from the working classes, and from churches.

LEAD-POISONING.

DR. SINCLAIR WHITE, the medical officer of health for Sheffield, has recently published an excellent and interesting report on the action of the Sheffield water on the lead communication-pipe and its effects on the health of the community. A number of cases of chronic lead-poisoning occurred during last year amongst persons not engaged in any of the trades in which lead is used, analysis showing that the drinking-water in every case contained a sufficient amount of lead to account for the poisoning. An examination of the water-supply led to the fact becoming known that the water of only some parts of the town contained lead to any appreciable extent. Sheffield derives its water from two distinct sources, with separate systems of distribution; the first is from the hills around Redmires, which is collected in reservoirs near its origin, and runs in a conduit to a reservoir at Crooke, known as Hadfield Reservoir, whence it is distributed to certain high-lying districts; the other source is from the hills around Strines and Agden, which runs in a conduit to a reservoir known as Godfrey Reservoir, and is thence distributed to the two low-lying parts of the town. The persons who suffered from lead-poisoning resided in the high-lying districts. The Redmires water is collected from moorland, the surface peat varying in thickness from a few inches to several feet, and beneath this are shale and millstone grit of the carboniferous system of rocks; both the peat and shale contain iron pyrites, and the water was distinctly acid in reaction, the acidity being most intense in the higher portion of the collecting grounds. The Strines and Agden water was not acid. The cause of the acidity in the Redmires water was the subject of careful investigation, and it was found possible that this had resulted, firstly, from the action of soft water on the iron pyrites, giving origin to free sulphuric acid; secondly, from ulmic and humic acids, which are caused by the decomposition of vegetable substances; thirdly, from the atmosphere, which contains large quantities of sulphurous acid, the result of the large consumption of coal in the town. Assuming that the first two possible causes had been in force, the impregnation of the Redmires water is explained on the ground that this neighbourhood contains iron pyrites, while the water from Strines and Agden, from containing more alumina, which would neutralise the acid, would give less evidence of the presence of free acid. A further analysis of water taken from sources where the water had passed through new and old lead pipes showed that the former contained a much larger amount of lead than the latter, the former containing from 0·14 to 0·61 grain per gallon, whereas the latter contained from 0·14 to 0·42 grain per gallon. Again, long pipes led to greater pollution of the water than short ones, and the length of time the water had stood in the pipes was also directly related to the amount of lead contained. The report ends with a statement of the results of filtration: carbon and spongy iron filters removing all traces of lead. Dr. White deserves much credit for a painstaking piece of work. His report will be read with much interest by all concerned in public health administration.

A MYSTERY EXPLAINED.

A CURIOUS tale reaches us from Rochester, U.S., illustrating the belief held by some that there is mysterious sympathy between the individual and detached portions of his anatomy, or as the Americans would term it his "physical economy. It is related that a woman who had recently suffered amputation of the foot experienced acute pain in a corn on one of the toes—a fact the like of which often enough comes under the observation of the surgeon, and which, though marvellous to the patient, is easily explained on physiological grounds, for the irritation of sensory fibres of a divided nerve is *referred* to the terminal distribution of those fibres. But the most curious part of the story tells how that on disinterment of the foot a bandage was found tightly embracing the toe on which there had been a painful corn, and how that on the loosening of the fillet the quondam possessor of the foot gained complete relief from her distressing symptom. It may readily be imagined with what wonderment the woman contemplated "the spiritual link" which held in union her greater self and her far-removed extremity, without dreaming of what explanation on a more material basis of the phenomenon in question might be forthcoming. Granted the truth of the principle of "referred pain," as stated above, one need only suppose a coincidence of two altogether unconnected events—the cessation of the pain and the removal of the bandage—to explain the apparent association. But there is another element which should not be disregarded, which may have played an important *rôle* in delivering the woman from her suffering—namely, a psychical state, whether of expectancy or belief; or, on the other hand, mere emotion independent of the mind. It is well known how fear inhibits pain—e.g., most people must have experienced a diminution or cessation of toothache when brought within a measurable distance of the dentist's forceps; and yet, for all that, the physical basis of the pain can scarcely be supposed to have been withdrawn. In the case under consideration, the patient had been wont to associate the painful corn with tight pressure or other form of mechanical injury, and to feel relief on the withdrawal of the source of irritation. What more likely than that, on

Digitized by Google

learning how the enshrouded foot was "cramped" and "in an uneasy position," she should attribute the pain she now felt to its former cause, and, conversely, the deliverance from pain to the removal of the bandage. These are matters which in the uneducated nurture an innate tendency to superstition, but which to those having a knowledge of the physiology of the nervous system are only illustrations of the manifold ways in which mystery is uncloaked.

LAUDANUM-TIPPLING.

ACCORDING to Dr. O'Hanlon, medical officer to the Spennymoor Local Board, opium-drinking is prevalent to a surprising extent among women in the north of England. The possible ill-effects of the drug on the suckled infants of such women are obvious. Miners' wives appear to be most addicted to the habit, which is by its mode of exercise rendered only the more attractive, insidious, and doubly dangerous in its after injurious effects. The opium is drunk dissolved in proof spirit. These disclosures, as is well known, do not mark a new departure in the use of poisons. They are novel only as proving the extension of an old evil already noted as existing in some degree in every order of society. They inform us, moreover, of a combination of two pernicious practices, drinking and drugging. Experience has shown how hard it is for any governing body to control the abuse of alcohol, and it may be doubted how far the Legislature should proceed in this direction. In the absence of any such remedy, temperance education and agitation have already accomplished much by means of spontaneous effort. The case with regard to opium is different. While the beginnings of its action and ascendancy are in many cases less glaringly hurtful in the public view, and therefore, perhaps, less demonstrable by argument, its final effects on the system are at least equal to the results of drunkenness. Moreover, we are dealing from the first with a drug in the strict sense, a deadly poison, and a medicine, which has no legitimate use for any but a remedial purpose. It is clearly, therefore, within the power and duty of the common law to deny to the public, whether salesmen or buyers, their usurped discretion in treating this substance as a domestic commodity. The weakness of the Poisons Act is generally admitted, and in nothing perhaps is it more apparent than in these most recent proofs of its deficiency.

UNUSUAL RASH AFTER SCARLATINA.

THE report of a case of scarlatina followed by a secondary ambiguous rash on the fourteenth day, in THE LANCET of March 6th, by Dr. Julius Pollock, will be a source of consolation to those practitioners who have from time to time found themselves puzzled and unable to define and name those curious cases of septic infection of the throat in which an ambiguous rash is a common feature. Whenever the throat is the seat of an acute inflammatory affection, there appears to be a disposition to the absorption of, and impregnation of the blood by, some fermentive poison. If the case reported by Dr. Pollock is viewed apart from the attack of scarlatina, it becomes one of sore-throat followed by infiltration of the glands of the neck, irritation of the mucous membrane of the urinary tract, and impregnation of the skin to the production of rash, and, finally, septic thrombosis of the femoral vein. This group of symptoms is now and then seen in the surgical wards in cases of pyæmia. The rash varies from one resembling scarlatina, as best seen in surgical scarlatina, to another resembling measles; sometimes it is more in the nature of the first stage of an attack of acute herpes, but differs from herpes in not going on to the vesicular stage; or it may, like Dr. Pollock's case, resemble the non-scaly stage of psoriasis. In fact, the form of rash is very variable and often very transient, being seen one day and absent the next, with liability to recur. The copper colour of the rash to which Dr. Pollock refers is unusual in a strictly septic eruption, nor is it common for the rash to remain out so long as in this case. When a consultation between such accomplished men as Dr. Julius Pollock, Dr. Samuel Gee, and Mr. George Pollock leaves the exact nature of the disease undefined, it indicates an unexplored field for future clinical investigation by practitioners who see most of these diseases in family practice. Our readers will be interested in, and may be able to assist in answering, the questions raised at the end of the report of Dr. Pollock's interesting case of unusual secondary rash after scarlatina.

CHEAP NUTRITIOUS VEGETABLE FOOD.

AT a time when food is plentiful, but work and wages scarce, a timely hint on dietetics may be of service. The pecuniary advantage of a vegetable diet sufficient for the maintenance of healthy nutrition has been pleaded by a correspondent, and the subject is one deserving of consideration. Something may be said, indeed, on physiological grounds in support of such a diet. While the more easy and perfect assimilation by man of certain substances, especially of nitrogen, when derived from animal rather than vegetable tissue, must influence us in favour of a mixed diet wherever possible, there is no doubt that the human body can be maintained in vigour and efficiency on food from which meat is excluded, if enough of it be taken. The rural population, even in our own days, sustain themselves largely on this principle. Might not many of those who people "starving London," and other of our cities in a similar condition, benefit by adopting the same regimen? There are some, at all events, of the unemployed whose poverty does not prevent their acting thus. Meat and fish may not, perhaps, be purchasable even for one meal; yet enough oatmeal, flour, or pease-flour, might be had, at a less cost, to furnish food for several such. Beef-suet can be had for a trifle, as also can bones, and these will add considerably both in flavour and nutriment to the value of the farinaceous materials. The simplest cookery, if thorough, will make an excellent dish of any of these ingredients. The cheapness of such fare should not be allowed to discredit its utility. There is, we are told, and we partly believe it, some such tendency among the poor. Never has it been less justifiable; and we venture to hope that many who are now in straits, though not quite destitute, may be induced by these remarks to think well of provisions which are exceedingly cheap, and are yet esteemed in their plainest form by not a few in wealthier circumstances.

DESTRUCTION OF REFUSE IN KENSINGTON.

A GOOD deal of opposition has been raised to the proposal of the Kensington vestry to destroy their house and trade refuse from the north part of the parish by means of one of Fryer's destructors to be erected on a piece of land formerly forming brickfields. The opposition was based on the grounds of nuisance and injury to trade. As regards nuisance it is somewhat difficult to speak from experience, because few of the destructors in use limit their work to dealing with such comparatively innocuous substances as the house and trade refuse of Kensington will be; thus in some towns excreta, the contents of pail-closets, and sludge from manure works are also so dealt with. But we are bound to say that, even under those circumstances, it is astonishing how little nuisance is created, and such nuisance as exists is rather dependent on the site on which the destructor is erected being turned into a depôt for the various forms of filth and refuse to be dealt with, than on the mere destruction of the materials concerned. If the destructor in

Digitized by Google

Kensington be constructed as proposed, and if, to avoid accumulations of refuse, it be kept burning, as is intended, both day and night, we doubt whether any noteworthy nuisance will arise. So far as injury to business is concerned, it appears to be laundry work that is most in question; and unless the laundresses themselves succeed in convincing the public that clothes sent to them to be washed are likely to suffer by reason of the refuse works, no one will trouble his head about the destructor on these grounds. It is necessarily unpleasant to have a refuse destructor as a near neighbour, especially when the alternative is an open recreation-ground, and to this extent we are fully in accord with the complainants; but under existing conditions the destruction of refuse is becoming every year more and more necessary, and sites for destructors must be found.

LONDON HOSPITAL MEDICAL COLLEGE.

ON Tuesday last the corner-stone of the new buildings connected with this College was laid by Mrs. William James Thompson, the wife of the Chairman of the College Board. Among those present were the Chairman of the Hospital (General Keating, V.C., C.S.I.), Sir Wm. Rose Robinson, K.C.S.I., General Nicolson, C.B., the members of the hospital staff, and other friends of the hospital. The usual bottle deposited in the stone contained a copy of THE LANCET, the prospectus of the college, a scroll signed by the members of the staff and of the house committee, and the customary collection of coins. The new buildings practically represent an entirely new college for the London Hospital. Of the old college little now remains, nothing, indeed, except the chemical laboratory and theatre. The new erection will afford ample accommodation for the rapidly increasing number of students, will provide a new museum and lecture theatres, a new dissecting-room, a very spacious library, and a series of rooms—dining, smoking, cloak-rooms, &c.—which will be devoted to the "Club" for students connected with the hospital. Not the least important of the additions to the college is a series of small rooms for small classes and for special demonstrations.

AMBROISE PARE.

MALGAIGNE'S historical and biographical introduction to the three volume edition of Paré's works (Paris, 1840) has always been held in merited esteem as one of the most learned contributions to the literature of surgery; but it is defective in some important particulars, for want of documentary evidence. This has now been discovered in the National Archives of France and in family papers, and given to the world by Dr. le Paulmier, through Charavay Frères (Paris, 1885). Born at Laval in 1510 of very humble parentage, Paré overcame all the disadvantages of poverty and defective education, and worked his way, through a life full of vicissitude, to the position of surgeon-in-chief of two of the kings of France and of recognised leader amongst the surgeons of his time in all countries. He was a prolific author for over forty years, had a large private practice, and rode many thousand miles as chief surgeon to the national armies. No labour seemed too great for him. He found favour with no less distinguished contemporaries than Bernard Palissy and Coligny, Sylvius and Catherine de Medicis. When Henry II. was accidentally but fatally wounded in the famous tournament by Montgomery, Paré was first consulted, and then Vesalius attended from Brussels. A Huguenot, Paré was spared by Charles IX. in the massacre of St. Bartholomew; and the orthodox members of the Paris Faculty, who had waged a long and envious war against the master-surgeon, witnessed the double triumph of his morality and of his professional skill. Of nine children by two wives, three daughters survived him but no son. At his death, on Thursday, Dec. 20th, 1590, Paré was a wealthy man, and held a commanding position. He was interred two days later in the church of St. André-des-Arcs, and, contrary to the wish he had expressed, with great pomp. He was of middle height, and had always enjoyed robust health. Conscious of his great powers, he sometimes laid himself open to the charge of vanity, but his honour was never questioned. He was a hard fighter, but a faithful friend; and in the practice of his profession he won gratitude as much by his considerate kindness as by his consummate skill. He has come to be regarded as, beyond question, the father and founder of modern surgery.

REFORM OF THE CORONER'S COURT.

IT is disheartening to find that the subject of reform in relation to the coroner's court has been so effectually shelved by the abortive inquiries made from time to time during the last ten years with the ostensible purpose of effecting necessary changes. At the present moment the tribunal which is practically the most useful, though not the most efficient, part of the judicial machinery for the purpose of repressing crime stands in a worse position than it occupied before attention was pointedly directed to its defects. It is discredited, and those who are responsible for the conduct of its business are hampered in the discharge of their duties. It surely need not tax the time of the Legislature too heavily to discuss and pass a Coroner's Bill, if only a good working Bill embodying the reforms which have been so repeatedly indicated could be drafted and launched under ministerial patronage. The best plan seems to be to constitute the coroners local officers of inquiry with special qualifications as medical jurists and analysts, so that the facts to be afterwards dealt with by the purely legal tribunals may be thoroughly sifted by a technical court of first instance. The coroners thus acting would be available as assessors to the higher courts in special cases, or they might be empanelled as a jury in cases of need to determine issues involving special knowledge. The local coroner's "courts" or juries would thus be restored to their old position as corps of observation to see fair play—as it were—by the representative of the Crown, the "crowner" or coroner. There would be great convenience in considering this proposal just now while the Bill before the Legislature for the amendment of the lunacy laws is passing through Parliament, because there is much need of a local official before whom questions of lunacy might be raised; and the creation of a class of specially qualified coroners who were possessed of technical knowledge, and at the same time raised above the suspicion of bias by being wholly official, would greatly facilitate the working of the new statutes relating to the care and custody of lunatics.

PREVENTION OF RIVER POLLUTION.

A MEETING was held at the Mansion House on Wednesday, on behalf of the Society which has been formed to procure effective legislation for the prevention of river pollution. The Lord Mayor presided, and the meeting was attended by the Attorney-General, Lord Hardwicke, Mr. Hastings, M.P., and others interested in the question. The Attorney-General pointed out the objects which the Society had in view, and dwelt upon the reasons which had led to the failure of the legislation of 1876 to protect rivers from receiving sewage and the refuse from manufactures, and he urged that the only remedy was to be found in further legislation, which would enable the subject to be dealt with as a national question. If legislation is to be effectual, it was argued, the duty of protecting rivers must no longer be imposed upon local sanitary authorities, who are often themselves the chief offenders, and it must be open to all persons

Digitized by Google

affected by the pollution to set in motion the machinery for preventing its continuance. Mr. Norman Bazalgette spoke strongly in favour of a standard of impurity being fixed by law, so that no question should remain to be settled by those who have to enforce the Act, and he referred to that of the Metropolitan Sewage Commission as being the best that can be adopted. This is obviously debatable ground, and if the Bill which is introduced by Mr. Hastings pass the second reading, it may be expected that it will be modified in this as well as in some other respects in committee. But with the general principles of the Bill we are in accord, for the fact remains that the pollution of rivers is at the present time a standing danger to the country, and the Act of 1876 has been found altogether wanting in the means which are required for the effectual dealing with this danger.

EPSOM COLLEGE.

SIR ANDREW CLARK, Bart., has kindly consented to take the chair at the twenty-third festival dinner of the Royal Medical Benevolent College, to be held at the Holborn Restaurant on Thursday, May 11th. As the College has no endowment, the whole cost of maintenance of the fifty foundation scholars and the fifty pensioners has to be defrayed out of the annual subscriptions and donations; these, we regret to see it stated, have for some years past been insufficient for the purpose. The pressure for the admission of foundation scholars is so great that it will be lamentable if it should become necessary to reduce their number; but a reduction will be inevitable unless the regular income can be increased. Under these circumstances we are sure that the profession will "rally round" so distinguished and representative a chairman as Sir Andrew Clark, and will use their influence, which is great, with the public on behalf of an excellent institution, the benefits of which, by the way, are not altogether limited to the disciples of healing.

THE PEABODY BUILDINGS IN 1885.

THE Trustees of the Peabody Donation Fund have recently issued their twenty-first annual report, which relates to the year 1885. It is eminently satisfactory to learn that the sphere of usefulness of this fund is constantly enlarging. At the close of last year the population housed in the dwellings erected by and belonging to the fund exceeded 20,000, and the assets of the Trust, consisting almost exclusively of the various blocks of buildings, exceeded £881,000, or £381,000 more than the £500,000 originally bequeathed to the Trust by Mr. Peabody. The net income of the fund, arising from the balance of rents in excess of expenses, now considerably exceeds £20,000, and steadily increases from year to year; and as this net income is added to capital by reinvesting it by the provision of improved dwellings, there is practically no limit to the beneficial influence of the fund upon the housing of the poor in London. The buildings already in occupation at the end of last year contained nearly 5000 tenements, of which more than 3000 were tenements of but one or two rooms. The report states, moreover, that the average weekly earnings of the head of each family in residence at the close of the year was under 24*s*., and the average rent of each room very slightly exceeded 2*s*. These figures refute many of the objections that have been made from time to time against the management of the fund. With reference to the vital statistics of the population housed in the Peabody Buildings during last year, it appears that the birth-rate was equal to 45·2 per 1000, which was 12·7 in excess of the mean birth-rate in the whole of London. The death-rate, including the deaths in hospitals of inhabitants of the buildings, was 19·6, and was practically identical with the general London rate. The rate of infant mortality was 139 per 1000 of the registered births, and 9 below the average rate in London. The population of the Peabody Buildings is essentially a working-class population, and its mortality statistics have therefore special interest. For comparative purposes, however, it is necessary to bear in mind the age-constitution and other circumstances of the population, which materially affect its death-rate. It may be noted, as might be expected from the birth-rate, that the inhabitants of these buildings include an undue proportion of children—namely, 19 per cent. under five years of age, against 13 per cent. in London. On the other hand, only 3 per cent. of the Peabody population are of persons aged upwards of sixty years, whereas the proportion in the whole of London is 6 per cent. One other point should also be borne in mind. The statistics of the Peabody Buildings take no account of those residents who drift into the metropolitan workhouses, although nearly 13 per cent. of the total deaths in London last year occurred in workhouses. On the whole, however, after making allowance for these disturbing influences, the death-rate in these buildings last year affords evidence of satisfactory sanitary condition, although more detailed mortality statistics of this working-class population would possess especial interest.

UNSTRIATED MUSCLE IN THE KIDNEYS.

THE presence of a few scattered smooth muscular fibres in the kidneys has been noticed by several observers, and especially by Henle and Eberth; but Dr. Jardet of Vichy has, in a short memoir contributed to the *Archives de Physiologie* of February 15th, shown that there is a regular system of such fibres. Most of the text-books state that a layer of smooth muscular fibres is present in the pelvis and calyces, the origin of which is referred to the double muscular layer of the walls of the ureter. Henle describes a special muscular annulus, composed of longitudinal and circular fibres around each papilla, lying just beneath the membrana propria. The longitudinal layer ceases at the plane of the floor of the pelvis; the circular layer may be traced some distance into the renal substance. The function of these fibres is to drive the urine forwards from the papilla into the pelvis. Eberth found, in man, a plexus of unstriated muscular fibres with large meshes on the surface of the kidney. Some of these fibres dip into the cortical substance of the kidney. The system of fibres described by Dr. Jardet were first noticed by him in pathological specimens, but were afterwards found to be present in the normal kidney. The situation, when they came clearly into view, was in transverse and vertical sections of the pyramids of Malpighi. They occupied the perivascular conjunctival sheath of the vessels, and never extended far amongst the renal tubuli. The fibres are grouped into small fasciculi, which spring from the pelvis and run parallel to the larger arteries and veins, but do not constitute a complete sheath to any vessel. They become hypertrophied in lithiasis, in hydronephrosis, and in all chronic inflammations of the kidney.

ETHER AND OPIUM IN SMALL-POX.

DURING a recent meeting of the Medical Society of the Paris Hospitals, MM. Dreyfus-Brissac and Balzer mentioned that they had tried M. du Castel's ether and opium method of treating small-pox for a considerable time, and had convinced themselves of its efficacy. It consists in subcutaneous injections of ether, a daily dose of from fifteen to twenty centigrammes of opium being administered by the mouth. In severe and confluent cases the papules become abortive, suppuration is diminished, and the general improvement is rapid. M. Balzer prefers administering the ether as well as the opium by the mouth, but M. du Castel considers this less efficacious than the hypodermic method.

COMPLIMENTARY DINNER TO SIR W. ROBERTS.

ON Saturday, the 6th inst., the members of the medical profession of Manchester and the district gave a complimentary dinner to Sir William Roberts, in recognition of his great services to medical science, and to congratulate him upon the honour of knighthood recently conferred upon him. The dinner took place at the Queen's Hotel, Manchester, Dr. Henry Simpson presiding, and there were about sixty guests. All the hospitals of the district were well represented by the presence of members of their various staffs, and there were also a number of other gentlemen, most of whom had either been fellow-students of Sir William Roberts, or had been for many years intimately associated with him in Manchester. After dinner the President, having given the usual loyal toasts, proposed the health of Sir William Roberts, whom he had intimately known from the time when they were fellow-students at University College Hospital. He referred briefly to Sir William's fruitful professional career, from the publication of his first essay on "Wasting Palsy" onwards, alluding more especially to his "Urinary and Renal Diseases," and his more recent work on Digestion. In doing so he emphasised the care which Sir William had always taken to make his work of real and lasting value, and not to write so as merely to catch the ear of the ὁι πολλοι. The toast was drunk with the greatest enthusiasm. Sir William Roberts, in his reply, cordially thanked his friends for the welcome they had given him, and dwelt upon the good fellowship and unanimity of the members of the medical profession in Manchester. The President's health was given by Dr. Buchanan, of the Local Government Board, who related sundry amusing anecdotes of the days when Sir William Roberts, Dr. Simpson, Dr. Briggs, Mr. Smart, he himself, and many others present were fellow-students with Sir Henry Thompson, Sir William Jenner, and others whose names are of world-wide celebrity. Dr. Briggs then proposed the health of Mr. Lund, who briefly replied, after which the evening was concluded with songs from Dr. Simpson, Mr. Dowse, and Mr. Luckman. The necessity imposed upon many of the guests of catching trains to outlying towns caused a somewhat early termination to a most enjoyable evening.

A HIGHLY PRAISED DIURETIC.

THE treatment of dropsy with Apocynum Cannabinum (American Indian hemp), by no means to be confounded with cannabis indica, was lately the subject of an interesting paper read by Dr. Andrew H. Smith before the New York Academy of Medicine in the section of Materia Medica and Therapeutics. This plant is indigenous in America, and has long been used and prized for its diuretic properties. Dr. Rush called it "the vegetable trocar." Dr. Mott used it, but thought it too active for any but sthenic cases. In 1869 attention was re-directed to it by Dr. Harvey Jewett of Canandaigua, N.Y., who, "as a tonic and diuretic," regarded it as more efficient in the cure of general anasarca and in removing the accumulation from serous sacs than all other remedies known to the profession. In atonic cases he recommended small doses at short intervals. A rapid cure was the result in his hands, where there was not incurable organic disease. The drug has a place in the Pharmacopœia of the United States, in the form of powder of the root and a tincture prepared from this (see Martindale and Westcott's Pharmacopœia). But Dr. Jewett used a decoction made with one drachm of the bark of the fresh root to eight ounces of water; of this the dose was half an ounce every six hours. In 1875 Dr. Hutchins related a case of general anasarca, with pleuritic effusion and hydropericardium, extreme dyspnœa, and enormous distension, in which some of the drug gathered by and got from Jewett acted so that in forty-eight hours the man who had been so frightfully distended was reduced to a skeleton. Dr. Smith's cases were three in number. One was a failure, perhaps owing to a bad selection of the drug. In another—a case of renal disease, with scanty urine and threatening uræmia—the apocynum excited profuse diuresis, and danger was averted. The third case was one of general anasarca, ascites, and œdematous lungs, with extreme dyspnœa, face cyanotic, and mind wandering. All diuretics had failed, and it seemed unwise to annoy the patient with further treatment; but as a *dernier ressort* the apocynum was tried, and the quantity of urine was raised from between six and twelve to thirty ounces, and the urgent symptoms were relieved. The drug evidently deserves attention, and to have its action and uses defined.

THE ABUSE OF PROVIDENT DISPENSARIES IN MANCHESTER.

THE Manchester and Salford Provident Dispensaries scheme is a very large one, and ought to be worked upon very strict principles; but we have had occasion to question whether the dispensaries were not open to great abuse, chiefly on account of the abolition of the rule which prescribed a wage limit beyond which persons were not admissible as members. Very explicit confirmation of our views is supplied in a letter by a working man published in the *Manchester Guardian*, and which is so much to the point that we give it in full.

"Pendleton, Feb. 27th, 1886.

"DEAR SIR,—I would have answered your note sooner, but I have been working late and have not had an opportunity before now. While I sympathise to a certain extent with the object of the provident dispensary, yet I fear and know that it is largely taken advantage of by the improvident. I have known many members of above earning from 40*s.* to 60*s.* per week (piecework), able to lose and win heavy bets, stop days off work drinking, and otherwise squander their earnings, and yet take advantage of this and other charities. Of course it is a long-vexed question how to deal with such. Still I presume it is more of the well-to-do you want to know, and of these I do know some—one a family of five (wife, husband, and three children); husband 35*s.*, and children earning upwards of 30*s.* per week. I am not quite sure if they are all in, but I know the husband is a member and recently received benefit. I knew a young man (single), wages upwards of 36*s.* per week, who received considerable benefit. He has lately left Pendleton. Also I know a man (married, two children), wages over 40*s.* per week, who received benefit. He has lately left Pendleton. I have not the paper, but I think Mr. Harwood referred to some rule that applicants for membership were inquired into before being admitted. This is certainly not the case. I joined myself among upwards of a hundred more in the works some three years ago, and I think I am safe in saying not one case was inquired into if suitable; certainly mine was not, and the question of wages was not mentioned by the agent who came down to propagate the scheme.

"I am, &c., ——."

LYING-IN HOSPITAL MORTALITY.

THE reports of the mortality of lying-in hospitals form much pleasanter reading than it used to be. That of the General Lying-in Hospital, York-road, Lambeth, is before us. The medical report, by Dr. Williams and Dr. Champneys, is very satisfactory. There were 395 women confined in the hospital, of whom 4 died. As out-patients 850 women were confined, and 2 died. The cause of death of the two out-patients is not stated. At first sight the death of four in-patients looks unsatisfactory, but in a footnote it is explained that only one of these died of septicæmia. Two women were admitted in advanced consumption, and the fourth death was from chronic renal disease. The exclusion of such cases would improve the results, but they would reflect little credit on the humanity of the physicians.

Digitized by Google

A hospital exists, not for show tables of mortality, but for the accommodation of the afflicted. We have before alluded to the care with which antiseptic douches, ventilation, and cleanliness are practised in this institution, and to which, doubtless, the abeyance of septicæmia is largely due. In the last five years 1508 women have been delivered, of whom 11 have died, or 1 in 142; 218 nurses have been trained, and 52 midwives, of whom 42 have obtained the diploma of the Obstetrical Society. As regards the mortality, it is to be noticed that it is the total mortality from all causes, including diseases unconnected with childbirth. Cases leaving before recovery had taken place were traced, and the result is embodied. This care and candour are to be much commended. We have only one fault to find with the medical report, and that is its brevity. Short of mortality, what were the complications of parturition, and how were they dealt with? What was the average duration of labour? What the proportion of primiparæ? What the frequency of instrumental cases? What the defects or diseases of the infants born in the hospital (400), of whom 10 were stillborn and 12 died after birth. The last paragraph of the general report is devoted to a warm and well-earned acknowledgment of the services of Dr. Williams, whose other duties have compelled his resignation, but who leaves the hospital in a very different position from that in which he found it.

THE URINE IN PUERPERAL ECLAMPSIA.

M. DOLERIS has found that some specimens of the urine of patients with puerperal eclampsia give, on drying, crystals whose composition is at present undetermined, but which are slightly soluble in alcohol and soluble in acidulated water, and a somewhat concentrated solution of which injected into animals killed a rat and three sparrows, while comparative experiments made with a portion of solution containing no crystals produced no effect. M. Doleris found a normal amount of urea in the blood of two patients dead of the disease, but an increased amount in that of two others who were cured. In one case only were soluble and toxic ptomaines met with. He believes that puerperal eclampsia is of an infectious nature, for it is not only the kidney which is affected but other organs, the liver in particular presenting characters more or less allied to those noted in acute yellow atrophy.

THE PORT OF LONDON.

THE provision of a new steam launch has led to a large increase in the amount of inspection carried out by the officers of the Port Sanitary Authority of London, and as many as 12,663 vessels were thus dealt with during the latter half of 1885. This work tends steadily to improve a large amount of shipping of various nations, and thus to conduce to the general benefit of crews and passengers. During the past half year an unusual number of structural alterations have been made with a view of improving the hygienic condition of vessels, and many of these have been found necessary even in the case of perfectly new vessels. It would doubtless save much expense in the long run, if the medical officers of ports were consulted as to the sanitary aspects of the question whilst the ships were building, for it is of necessity a somewhat costly thing to alter forecastles when the vessels are finished, and Dr. Collingridge does well to point this out. Special precautions were taken to prevent the importation of articles of infected clothing belonging to persons who had died of cholera and other spreading diseases. As regards cholera itself, no case or suspected case appears to have entered the Thames; but the arrangements for isolation and disinfection, which are well devised and excellently carried out in the case of the other dangerous infectious diseases, were kept in readiness. During the month of August a large number of boys in the training ship *Warspite*, lying off Charlton, were attacked with diarrhœa, and after a very exhaustive inquiry into its possible causes, Dr. Collingridge finds himself compelled to attribute it to the foul state of the river. The boys were all seized in the night; and the worst nights, in point of numbers attacked, were those when the river was very bad; whereas when the river was less foul the disease subsided; and we feel that, so long as the Thames remains in its present state, the report is correct in describing so much of it as lies above Gravesend as an improper place for mooring such a vessel. The port hospital and its ambulance launch are kept in good order, nuisances are well controlled, and the enforcing of the provisions of the Canal Boats Acts, which has now been thrown upon the Port Sanitary Authority, has been commenced in a manner that gives good promise of efficient administration in this matter.

THE FUNCTIONS OF THE CORPUS STRIATUM.

HERRN BAGINSKY and Curt Lehmann brought before the Physiological Society of Berlin, at the meeting on Nov. 13th, 1885, the results of their researches on the functions of the corpus striatum. They remark that as these organs lie deeply embedded in the brain they cannot be reached without considerable damage being inflicted on other parts, and they took pains to adopt a method which should minimise this injury. They found the plan which gave the most exact and uniform results was to plunge a fine glass tube into the corpus striatum and place the other extremity of the tube in connexion with an exhausting syringe, by which the substance of the corpus striatum could be sucked out. The experiments were made on rabbits. If that part which projects into the ventricle were removed, the phenomena presented were that the fore and hind limbs of the opposite side were extended if the animal were previously in the sitting position. The extremities, and especially the anterior limbs, could easily be placed in anomalous positions, in which they remained till a stronger stimulus was applied. The movement of the extremities offered a certain resistance to the hand of the operator, which was greater than that of the opposite side. No motor defect was observed when the animal ran or made other voluntary movements. The temperature of the body remained normal, or only rose slightly and at a late period. The animal showed great excitability and much tendency to fear upon various sense impressions, making energetic efforts to escape by jumping from side to side. When the brain substance was removed down to the corpus striatum, without injury to that body, the same symptoms were observed, except that the rise of temperature was more common and greater. The authors of the memoir therefore arrive at the conclusion that the functions of the corpora striata do not differ materially from those of the superjacent brain substance.

ISOLATION ARRANGEMENTS AT DERBY.

WE are glad to find that the Corporation of Derby have at last decided to erect a permanent hospital for the isolation of infectious diseases. The experience of Derby in this respect has hitherto not been fortunate, except in so far as it has been useful in preventing the sanitary authorities of other districts from erecting temporary buildings under the influence of panic. Such buildings rarely answer the immediate purposes for which they are erected, and their after history is one which is full of warning, for the buildings are often allowed to decay, and they deter people from accepting the isolation offered them; or if they are kept in decent repair they are very costly. And, worse still, the

Digitized by Google

existence of these barn-like buildings prevents the erection of proper hospitals. Derby, after some thirteen years' experience of such a building, now intends to erect a proper hospital of thirty-two beds. The number of beds is by no means excessive, amounting as it does to one bed for every 2800 inhabitants; but the County Infirmary has a special fever pavilion, and the immediate isolation which may be expected to follow on the notification of infectious diseases which is compulsory in the borough may tend to make a larger amount of accommodation unnecessary. From the report before us we learn that no Isolation Pavilion has been provided for. We should counsel the authority to reconsider this matter, for if they do their work promptly and efficiently they will stand much more in need of a pavilion containing accommodation in separate small ward-rooms for one and two patients, than for large ward-buildings so designed that if a single patient suffering from one infectious fever is received into any one of them, no other case of a different disease can be taken into it. It has more than once happened that authorities with two large pavilions have been obliged to keep all their available accommodation in working order because they happened to have taken in two patients who were suffering from two different diseases. An isolation pavilion such as has been designed by the Local Government Board would, under these circumstances, have provided better and more suitable accommodation in two small rooms, and this at a minimum cost for maintenance and administration.

AN EXPERIMENTAL INQUIRY INTO THE NUTRITIVE VALUE OF BEEF EXTRACTS.

AT a recent meeting of the College of Physicians of Philadelphia Dr. Thos. J. Mays read an important paper, in which he described the results of a series of careful experiments made with various beef extracts upon the isolated frog's heart. An abstract of the paper appears in the *Medical News* of Philadelphia of Feb. 27th. Dr. Mays conducted his experiment as follows. The Kronecker-Bowditch heart apparatus was used, and was connected with a proper recording apparatus. By means of a double cannula it could be supplied with any desired material, and in order to keep it pulsating regularly, minimum shocks of one Daniell's cell through a Dubois sliding induction coil were employed every four seconds. The heart was first of all well washed out with a ·6 per cent. saline solution, after which it was allowed to work with the same until all its stored-up material was exhausted and its pulsations reduced to zero. Then a weak solution of the inorganic salts of the beef extract was tested, and found to fail in every instance to induce cardiac contractions; a solution of urea failed in the same manner. Solutions of various beef extracts diluted with the ·6 per cent. saline solution were then employed. Solutions of 1 in 100 and 1 in 500 failed to restore contractile power to the heart, but when the extracts were diluted in the proportion of 1 in 666 to 1 in 2000 the heart's action was revived and maintained. This having been ascertained, another series of comparative experiments was undertaken. A heart, having been prepared as before, was filled with a 2 per cent. solution of dried bullock's blood, and the number of times the heart beat was taken as a standard. The heart was then washed out with the saline solution and filled with one of the fluids to be tested, and the number of contractions counted. In this way the nutritive value of these solutions of beef extracts was compared with that of dried bullock's blood, which is stated to be one-third of fresh blood. Five beef extracts were thus tested, and their value was found to be very similar, for if the standard of dried bullock's blood be taken as 100, the contractions excited by these solutions were respectively 58, 59, 60, 61, and 62, which, allowing for errors in the experiment, may be taken as a uniform figure, 60. A mixture of beef extract with milk and gluten, sold under the name of beef peptonoids, ranged at 74. From these experiments Dr. Mays infers that solutions of beef extracts are absorbed and assimilated by the isolated frog's heart, that they contain material which has the power of inducing muscular contraction, and that they are entitled to be called nutrients in the full sense of that term. In a further series of similar experiments, Dr. Mays hopes to show which of the many organic constituents of these preparations really possess this power; but owing to the difficulty of isolating them this part of the investigation has not at present been completed. In view of the great diversity of opinion as to the nutritive value of beef-tea and meat extracts of all kinds, accurate scientific observations, such as those of Dr. Mays, are of considerable interest and of great practical value.

THE PASTEUR INSTITUTE.

THE institute that is to be named after M. Pasteur will stand as a monument of his great services in the cause of suffering humanity. International in its scope—for it is reckoned that the single establishment will be able to cope with the average annual number of cases of hydrophobia,—it is but right that the subscription list should be open to the world at large. The estimated cost of the edifice is 80,000 francs. Already a large sum has been contributed. Paris will add by this projected scheme one more claim to be regarded as the first city in the world.

SIMPLE CONTINUED FEVER.

PROBABLY no investigations in medicine are more directly responsible for the saving of human life than those which caused the three diseases—typhus, enteric, and relapsing fevers—to be distinguished from each other. They have enabled the etiology of these affections to be definitely studied, and have been the foundation upon which has been erected the whole superstructure of the means for their prevention. Clinically, these diseases differ from each other in so many important particulars that to those who study medicine at the present time there is almost a feeling of surprise that they were so long confounded with each other. But the knowledge which was required to enable them at first to be differentiated was not at once available. Observation was based upon previous observation, and many workers were required to add their contributions to the total sum necessary for the attainment of a definite decision. The work, however, which has already been done is not all that is required for a proper understanding of the acute febrile affections, which still cause loss of life in this country. During the decade 1871-80 as many as 25,643 deaths were registered in England and Wales from "simple continued fever." Under this heading is doubtless classed more than one disease, and before there is any possibility of the prevention of this vast mortality prolonged and patient work must enable each to be clearly understood. Fortunately the opportunities for their study have increased, and are still increasing year by year. Improved microscopical and biological methods add to the hope that by their means first one point and then another will be gained until the whole can eventually be trusted to teach lessons not less valuable to mankind than those which served to show that the conditions which give rise to typhus are altogether different from those producing enteric fever, and that both sets of conditions differ from those upon which relapsing fever is dependent. Such work as Mr. Alfred Lingard is now carrying out in connexion with disease caused by the air contents of sewers is especially of the kind likely to lead to definite gain, and the Grocers'

Digitized by Google

Company deserve the gratitude of all interested in the public health for the opportunity they have given for his researches. These have already been fruitful in their results, and the observations which are in progress will, we anticipate, be the beginning of a better understanding of those mysterious affections which we have been content as yet to class together as simple continued fever. The profession will gladly await the completion of these studies. The premature publication of investigations which are still in progress is to be deprecated, for it is above all things necessary that every observation should be fully substantiated.

THE HEALTH OF THE PREMIER.

WE learn that Sir Andrew Clark at his morning visit on Thursday found the Premier progressing favourably, but still needing to carefully keep his room. Mr. Gladstone is suffering from a feverish bronchial catarrh without complication. Obviously, in the present season, such an attack must not be neglected; but it is confidently expected that Mr. Gladstone will be able to be in his place next week.

MEDICAL SOCIETY OF LONDON.

A VERY successful dinner was held on Saturday last at the Holborn Restaurant, Dr. W. M. Ord, the retiring president, being in the chair. In responding to the toast of "The Army, Navy, and Reserve Forces," Sir Guyer Hunter, M.P., considered that the "capitation fee" for Volunteers was altogether inadequate. Dr. Broadbent proposed the toast of "The President," and spoke in feeling terms of their friendship and of the success that had attended the Society's meetings during the past year.

EFFECT OF LIGHT ON BACILLUS ANTHRACIS.

ACCORDING to M. Arloing, gas-light is slightly prejudicial to the growth of the bacillus anthracis. The sun-light of summer rapidly suppresses the vegetation of the spores if the rays of light can penetrate easily the fluid media that hold the bacillus in suspension. Sun-light also interferes with the growth of the mycelium, and is an agent as effective as heat for the attenuation of the virus of charbon. The effect of sun-light is due to the action of all its component rays; the effects are proportional to the intensity of the light and the transparency of the media.

CLASSICAL EDUCATION AND SOCIAL POSITION.

A SOMEWHAT long debate has taken place in the Bavarian Landtag on the question of the admission to the University faculties of medicine of students who have received their preliminary education in real gymnasia—that is to say, in institutions corresponding to the modern sides of our public schools, where Greek is not taught, but greater attention is paid to science and modern language than in purely classical schools. This proposal did not command the sympathy of the majority of the members, although it was admitted that a knowledge of Greek is by no means necessary to enable a student to become a first-rate scientific practitioner. The *Münchener Medicinische Wochenschrift*, referring to this subject, remarks that in many other countries a classical training is not required of medical students, but that the want of this is found to lower the social status of the profession in those countries—this being notably the case in England—"where even for the highest medical diploma, M.R.C.P., a knowledge of Greek is not compulsory. Nevertheless medicine in England has produced much valuable original work; but the profession is obliged to be content with a subordinate position, the highest circles of society to which the clergyman and the lawyer have access being closed to the doctor;" and in particular he is never raised to the dignity of the peerage, "the prejudice against the medical profession being doubtless due to the fact that the majority of English doctors are lacking in refined classical education" (!) With this sad example as a warning, let the profession in Germany "hold fast by the talisman which is its only security in claiming a position equal to that of the other learned professions—a classical training." Though it is much to be desired that as high a standard of preliminary education as possible should be insisted on, it can hardly be true that the cause of the "subordinate position" which the medical profession is said to hold is due to the want of a knowledge of Greek, which is probably far less usual amongst doctors than amongst military and naval men, whose profession of arms has certainly no reason to complain of any want of social consideration, and which leads pretty frequently to a seat in the House of Lords—a Chamber, too, which, fortunately perhaps for some of its hereditary members, does not close its portals to those destitute of a "refined classical education."

THE LATE PROFESSOR PANUM'S SUCCESSOR.

FOR the late Professor Panum's post of Professor of Physiology in the University of Copenhagen four candidates presented themselves before a committee of experts, one of whom, Professor Holmgren, had been specially invited from Upsala. Each candidate read papers on various topics, and the committee decided in favour of Dr. Chr. Bohr, who had been assistant to Professor Panum and had been specially recommended by him as his successor. The other candidates were Dr. Buntzen and Dr. Vogelius.

THE INCUBATION PERIOD OF SMALL-POX.

PROF. EICHHORST of Zurich has had an opportunity of accurately observing the incubation periods in three cases of small-pox occurring in a medical man and two medical students. They were very nearly alike, and much shorter than is commonly supposed, being respectively nine days eight hours, nine days eight hours, and nine days fourteen hours; whereas it is usually stated to be from twelve to fourteen days.

ON the 8th inst. the death occurred, at his residence in Salisbury, of Mr. R. W. Read, F.R.C.S., Deputy Inspector-General of Army Hospitals. Mr. Read studied medicine at St. George's Hospital, and became a Licentiate of the Society of Apothecaries and a Member of the Royal College of Surgeons in 1841, a Fellow of the Royal College of Surgeons of England in 1857, and a Fellow of the Royal College of Physicians of Edinburgh in 1859. He was appointed an assistant-surgeon in the Army Medical Department in 1844, became a surgeon in 1855, surgeon-major in 1864, Honorary Deputy Inspector-General in 1869, and was placed on half-pay in the same year. Mr. Read, who was a magistrate for the city of Salisbury, had contributed papers on "Revaccination in the Army" and "Radical Cure of Hydrocele," &c., to the columns of this journal.

THE Vienna Town Council on the 5th inst. discussed and rejected the proposal of the Princess Metternich that medical men should be sent from that town to Paris to learn M. Pasteur's method of treating hydrophobia; but a resolution was passed that the Government should be requested to take the matter into its own hands.

THE Countess of Dufferin has written for the April number of the *Asiatic Quarterly Review* a paper describing the objects of the Fund for supplying female medical aid to the women of India, which is identified with her name.

ON the 3rd inst. the death occurred at Rochester of Deputy Surgeon-General Alexander Guthrie, principal medical officer of the Chatham district. The deceased officer, who was in his fifty-fourth year, joined the Army Medical Service in 1854, and served in India during the mutiny, being present at the action at Cawnpore and the siege and capture of Lucknow; he served also in the Trans-Gogra campaign and the Afghan expedition of 1880.

AT an investiture held by Her Majesty at Windsor Castle on Tuesday last, George Edward Paget, Esq., M.D., with other Knights Commanders of the Order of the Bath, was introduced into the presence of the Sovereign, who conferred upon him the honour of knighthood, and invested him with the insignia of the Civil division in the Second Class of the Order.

ON the 10th inst. the death occurred of Dr. John Storrar, the representative of the University of London in the General Medical Council and late chairman of Convocation of that University. We hope in a future number to give some particulars of the services rendered by the deceased to the cause of medical education in this country.

THE Professorial Senate in Vienna have under discussion the question of establishing a dental school in connexion with the medical faculty. A committee has been appointed, consisting of Professors Albert and Billroth and Drs. Schiff and Sternberger, docents in odontology, to draw up a scheme for consideration.

THE outbreak of yellow fever on board H.M.S. *Urgent* at Port Royal which we mentioned in a recent issue still continues, and the vessel has been removed to the quarantine ground and thoroughly cleansed and fumigated. Amongst the latest deaths was that of Mr. Anderson, surgeon of H.M.S. *Tyne*.

DR. DUDGEON of Pekin, who is said to possess great influence with the leading statesmen of China, is writing a History of Opium. The work, which is partly in type in Pekin, will contain much novel information concerning the early history of the supply and its introduction into China.

IN an action brought by the governors of the London Hospital to recover possession of more than 100 houses in Whitechapel, judgment was given on the 9th inst. for the plaintiffs. The action was brought against the leaseholders on account of breach of covenant to repair.

WE understand that the Colleges of Physicians and Surgeons of Edinburgh and Glasgow have just decided to throw open to women their conjoint examinations and "triple qualification" in medicine, surgery, and midwifery.

TELEGRAMS from Venice received in Rome announce that a case of cholera has occurred on board a brigantine, which arrived there a few days ago from Greece. The vessel was immediately sent to the quarantine station.

DR. ROBERT SAUNDBY has been appointed consulting physician to the Birmingham and Midland Counties Hospital for Women, in succession to the late Dr. Heslop.

THE annual report and balance-sheet for 1885-86 of the Vaccination Officers' Association, which has just been published, is a highly satisfactory one.

THE ILLNESS OF THE LATE MR. COOPER FORSTER.

THREE possible causes for Mr. Cooper Forster's illness were discussed by his medical attendants, and the post-mortem did not satisfactorily determine which of them or any other was the efficient one. The deceased gentleman left London for Cannes on Jan. 21st, and stayed there about three weeks; he then proceeded to Nice, where he remained a few days, and then on to Mentone. He was here but a few hours, and then returned straight home, arriving on Feb. 24th. At the beginning of the latter month he felt unwell, and after that he gradually lost his appetite and strength so as to be unable to take his usual walks, such as he had accomplished on his first arrival at Cannes. During the last week of his sojourn abroad he ate scarcely anything, until his appetite at last entirely failed, and he at once resolved to return home. He was unable to secure a "coupé lit," and was obliged to take his seat in a crowded carriage, his fellow-passengers kindly affording him as much opportunity as possible for rest. He ate nothing during the journey, and when he arrived home his servant was struck by his deadly appearance and with difficulty got him to bed. When I saw him he had a most haggard look, spoke in a whisper, as if suffering from the most extreme exhaustion. After a few hours he became very feverish, his tongue parched and hard, and his temperature 103°. This temperature was reached each successive afternoon, falling two degrees in the morning. His loathing for food was extreme, and most of what he took he rejected. Dr. Habershon then saw him, and was unremitting in his attention until the end. No maculæ appeared and no diarrhœa. He passed a very restless night, and on the following day could still take but little food. Dr. Habershon suggested some effervescing quinine, but he refused a second dose. We were first in hopes that his loss of appetite from foreign living was the sole cause of his illness, but we subsequently believed that he must have been the victim of typhoid fever. Sir J. Paget and Mr. Hutchinson discovered no cause for blood-poisoning, but the latter thought that a chronic skin eruption from which the patient suffered might be important. There was a painful spot in the left arm, which he attributed to a sprain in fishing. On the third day he took his food, stimulants, and quinine better, and we believed we saw an improvement. On the fourth day he continued to take a fair amount of nourishment, but in the evening became more prostrate, pulse more feeble, and gradually sank.

Dr. James Anderson and Mr. J. Hutchinson, jun., made the post-mortem examination. They found the organs congested, as is usually the case in those dead of blood diseases, and they thought the kidneys were not quite sound. These organs acted most efficiently during life. There was no disease of the intestines. This fact excludes the question of typhoid—unless, indeed, it may exist without the usual phenomena in persons of advancing age. In these Peyer's patches are inactive or atrophied, a reason given by Dr. Tweedie why typhoid fever does not affect aged persons. If the theory be true that Peyer's glands first receive the germ and then develop it until they become the infective source of the disease, it might even then be a question whether the system would be completely proof against the effects of the typhoid poison, even if these glands no longer existed. If so, it might kill without the usual intestinal lesion, just as scarlatina may prove fatal without a rash, or variola without pustulation. In typhoid, however, the anatomical basis is supposed to lie in the intestines, and, with our present views, the possibility of its existence without this must be rejected.

As regards Mr. Forster's illness having been due to a subacute gastritis, brought about by unpalatable food, there is much to be said in its favour. The capability of this producing a febrile condition is set at rest by the observation of Sir J. Paget when we talked it over in consultation. Sir J. Paget had a relative, a clergyman, working hard in the East-end of London, and, forgetful of the necessity of eating good food, he became so much impoverished that he was obliged to desist from his labours, but by care and feeding soon regained his health. During the time of his illness the temperature of the body was much above normal. One is aware

Digitized by Google

that in children the fever accompanying gastro-intestinal disorder is very high, and to this complaint gastric fever was formerly appropriately given. The term is now discarded, as it was constantly substituted for the more specific term typhoid; nevertheless, there is much need of the expression, since the fever is the most marked symptom, and the gastric disturbance not sufficiently defined to allow of an anatomical name. Our patient might be said, then, to have a gastric fever, and brought about much in the same way as in children—by improper diet. He had not travelled during youth, and when of late years he had gone abroad he had on the two occasions suffered much from the living. I met him once at Cologne, and he was then ill, suffering from gastro-intestinal disturbance and looking very haggard. I prescribed for him, and he hurried home. On the other occasion, his son-in-law informs me, he became very ill and lost flesh. He was naturally a good feeder and liked good things; the foreign *cuisine* was not to his taste, and he could rarely obtain a meal to his order. Everyone must have known friends, if he has not suffered in his own person, affected by strange viands. In spite of the variety of dishes, the perpetual iteration of the same sauces to accompany what the *ménu* may please to call fish, flesh, or fowl, produces at last absolute disgust, until the appetite altogether fails, the tongue becomes coated, and a change of residence is absolutely necessary. In Mr. Forster's case there were two precedents exhibiting the ill effects of foreign diet. In the last and fatal instance he remained abroad until he absolutely ate nothing, fell into a state of inanition, and then took a journey of thirty-six hours in the bitterest weather. It may be remembered, too, that his character was such as was likely to make him suffer more than persons of a placid disposition. Although an amiable man and good-natured to an extreme, so that he was never so happy as when he was regaling his friends around him, he was imperious. In an English hotel his presence was soon known to host and waiters, and his dinner and wines were at his dictation and not theirs; or on a railway journey, station-master and guards soon found that they had a passenger to be respected. But in a foreign land he had to succumb. Often he could not get his meals *à la carte*, but was forced to sit down to the "filthy *table d'hôte*," and against his will be thrust into the last seat of a crowded railway carriage. He was thus liable to be in constant opposition, instead of accommodating himself to the novel surroundings. All these circumstances must be taken into consideration in discussing the cause of our friend's death. From what I knew of him, I believe the inanition caused by want of accustomed food and the annoyance of foreign manners were sufficient to account for his fatal illness.

SAMUEL WILKS.

MEMORANDA AS TO MR. COOPER FORSTER'S ILLNESS.

BY JONATHAN HUTCHINSON, F.R.C.S.

The death, after a very short illness of an obscure nature, of one so highly esteemed and widely friended as Mr. Cooper Forster has naturally excited much and painful interest in professional circles. I had written out the following memoranda for my own use, but am induced by Dr. Wilks to offer them, with a few modifications, as an appendix to his own more valuable report. Dr. Wilks saw much more of our mutual friend during his last week of life than I did, and the case was essentially a medical one. Anything that I can add must be taken as of value only in reference to the dermatological part of the case. It will be seen that, even with the negative light afforded by the necropsy, the illness remains one which it is difficult if not impossible to name. All will probably agree that, whatever the original malady was, the unfortunate journey home much hastened its fatal progress, but on other points opinions will doubtless differ widely. The case is in itself an important one, and, apart from the personality of its subject, deserves to be placed on record in detail.

On Wednesday evening, Feb. 24th, I received a telegram from my friend, asking what time he could see me in the morning, his message implying that he intended to call on me. I at once sent a reply to Grosvenor-street, saying that I would call on him if he would let me know when he reached home. To this I had no reply, and consequently I did not call to see him till the afternoon. He had never opened my letter, having felt too ill to do so. On Thursday, February 25th, I called and saw him in bed. (Dr. Wilks had seen him before I did on the same morning.) He told me that he had got an eruption. He took off his night-shirt and showed me an eruption of brown papules on his chest and back. They were from the size of split peas to that of sixpences, slightly raised, and well margined. Some of them were rather smooth in the middle, but none of them actually glossy. On the right shoulder was one larger than the rest, as big as a halfpenny, and considerably raised in the centre. Most of them were rather thicker in the middle than at the margins, and shelved down gradually. He had few or none on the abdomen and limbs. He told me that the eruption had first been noticed on his chest before he left home for Cannes. He had left home on Jan. 21st, so that this would have been about six weeks ago. He said that whilst at Cannes and Nice he had been losing flesh and strength, had had a poor appetite, and had been "dreadfully constipated." He had travelled home alone, and I understood that his motive was to get advice as to his eruption, about which he was very anxious. He said that he had suffered much on his journey home, and had not been able to take any food. He looked very ill, but was perfectly clear in his mind. He got out of bed for my inspection of the eruption. I examined his throat and found no sores on the tonsils, but was struck with the red colour of all parts of his mouth—tongue, cheeks, palate, and fauces. I thought that his mouth must feel sore, but he assured me that it did not. It was not at this time dry, but simply very red. Dr. Wilks afterwards told me that it had been dry in the morning. He had been standing out of bed for a few moments for my inspection. The light was very bad—a foggy afternoon and a chamber candle. I suggested that his eruption looked a little like lichen planus. To this he replied that he had felt sure that I should call it "lichen planus." It will be observed by dermatologists that it did not closely conform to that disorder. I asked him whether he had worn any new vests, and he told me that he had, and that when he first noticed the papules he thought they must be due to the irritation of his vest, and had it changed. The spots, however, did not disappear, but continued to come out. At the time of my visit he had not used the thermometer, and I had not one with me. His pulse was then 110, at which he expressed surprise, and said it had never before been more than 80, and that he had "had neither rigor nor fever, but only felt desperately weak." He promised to use the thermometer in the evening, when he expected a second visit from Dr. Wilks. I advised him that, as no diagnosis could be made, he had better do nothing but keep quietly in bed and take light food. He had had some soup, but said that he had not the least appetite. I was to see him again by better daylight next morning. On Friday morning it was a dense fog, and I deferred my visit till the afternoon. On calling then it was still very dark, and I arranged to meet Dr. Wilks next morning, and did not go upstairs. On Saturday morning I met Dr. Wilks and Dr. Habershon. They had just been in his room, and as they suspected fever, and as it was deemed desirable to let our patient rest as much as possible, we agreed that I should not trouble him by further examination then, but that we should all meet on the next morning. On Sunday morning Sir James Paget was kind enough to join Drs. Wilks and Habershon and myself in consultation. Mr. Forster was looking much worse than when I had last seen him on Thursday afternoon. He was much more prostrate, and his tongue and mouth were so dry that he could scarcely speak so as to be understood. Yet he was perfectly himself, and quite acute in his remarks. The eruption on his chest and back was less conspicuous, but essentially the same as on Thursday. Some of the smaller spots on the upper part of the abdomen had been suspected to be those of typhoid, but there was really no definite distinction between them and others on his chest of the kind already described. He had taken an aperient, which had acted. He had been sick once or twice. He was too ill for us to make any very minute examination of the skin. He complained of pain in the left arm, and appeared to be sensitive to the slightest pressure on the humerus, just above the insertion of the deltoid. The skin looked red, and the arm a little swollen, but there was nothing positive. He flinched whenever the bone was touched, but no enlargement of it could be distinguished. We did not examine it much on account of his great debility. Just as we were leaving he reminded us that we had not looked at his throat. His mouth was everywhere quite dry, and sticky mucus hung about the pillars of the fauces. We all thought him very ill, and likely to die, but there was no reason to expect

Digitized by Google

such a rapid termination as that which followed. After this consultation I did not see him again, as it was deemed a medical case, but he was visited two or three times daily by his friends and colleagues, Dr. Habershon and Dr. Wilks. From what they have told me, I believe that he got rapidly weaker in spite of the free use of brandy, quinine, and fluid food. His intellect remained quite clear. His temperature was never (excepting once 103°) more than 102°, and his pulse often not 100. His tongue remained dry. On Monday morning he looked more depressed, and the unfavourable prognosis which we had all formed on Sunday was strengthened. At the evening visit on Monday he was so weak that his pulse flickered, and Dr. Wilks made a hypodermic injection of brandy. He was now clearly sinking. He died about 4 o'clock the next morning.

The post-mortem (on Thursday) was chiefly of interest in that it quite put aside the suspicion as to typhoid. The small intestines were most carefully examined, and there was no trace of disease. The most conspicuous condition found was acute hæmorrhagic congestion of both kidneys. There was some serous fluid in both pleural cavities and congestion of the lower and posterior parts of the lungs. These conditions had probably developed during the last few hours of life. No jaundice had been noticed during life, but there was at the necropsy yellow staining of all the viscera, which suggested its commencement. The heart was healthy. I am sorry that I cannot give a more exact account of the eruption than I have done. My first inspection of it was by candle-light in a fog, and as I expected to have other opportunities I did not keep him long uncovered. I believe that there were a few spots on the forearms, and Dr. Habershon told me that he had noticed one which was scaling. The spots were certainly not the smooth glossy ones of lichen planus, nor did they observe the rule as to uniformity of size.

It seems certain that Mr. Forster was in his usual health when he left for the Continent. Of this I have been assured by several who saw him just before he started. Whilst away he failed in appetite and strength, and used to complain of being weary, and was occasionally sick. That he was not very ill even when he started on his return journey may be assumed from the fact that he elected to travel alone, and that he left his family there. His reason for hurrying home was not that he felt very ill, but that he was anxious about his eruption and did not wish to consult anyone abroad. That his journey did him great harm there can be no doubt. It was performed in extreme discomfort. He was unable to take food or to sleep, and the weather was very cold. When he reached his house he looked like "a man stricken for death," and could only just manage to get upstairs. The one only objective symptom up to this date had been the eruption on his chest and back. This had begun before he left England, but had increased during his stay at Cannes. I cannot escape the conviction that this eruption was an important part of his illness. It was a very peculiar one, almost limited to his chest and shoulders. I think there was none on his lower extremities, and very few, and very small, spots on his abdomen. It had developed slowly, and there had been no glandular swellings and no sore-throat. Next to the rash the most conspicuous condition was the red and dry mouth. His tongue (on Sunday) did not show, as is often seen, a dry streak in the middle, but was as dry as it could possibly be in every part, rough, and red. Yet he would not admit that his mouth was sore. His temperatures were never very high (102°). His pulse did not quicken or fail in power at first at all in keeping with his appearance of prostration. It was only within twelve hours of his death that his pulse materially failed. He had noticed this himself, and told me that it had never been more than 80. My impression is that the case was one in which a patient, in whom a condition allied to lichen planus was developing, was subjected to cold and fatigue in a long journey, with the result of inducing local congestions and of greatly intensifying the constitutional disturbance which now and then attends this disease. Hebra at first taught that lichen ruber was always fatal, and only changed his opinion when he found the good results which followed the use of arsenic. Death, however, occurred, not quickly, but after an illness of some months or a year, and after the skin had become very extensively involved. Some cases of pemphigus are attended from the first by great prostration, and many would end speedily in death were it not for the use of arsenic. In such cases, however, the extent of skin affected is always much greater than it was in Mr. Forster's case. The redness and dryness of the mouth suggested that acute stomatitis was about to develop, and that the case might be allied to certain rare affections in which a very sore mouth is coincident with a skin eruption, and there is a definite tendency to death by prostration. It may be suggested that some poison (fever or other) was received during his stay in France, but it must be replied that the eruption was undoubtedly present before he left home. As to the real cause of acute pemphigus or lichen planus we know nothing. That it probably concerns the nervous system rather than the blood may be inferred from the manner in which arsenic cures them. Of cases in which a sore mouth was coincident with a skin eruption, and either ended fatally or threatened to do so, I have seen five or six examples. Four were in men about Mr. Forster's age, and two of these died at the end of five months. The eruption on the skin of these was mixed, being like pemphigus in part, and in part papular, with tendency to papillary growth. In another case (which recovered) only a few papules showed themselves on the backs of the hands. If Mr. Forster's case be one of this class, it is to be noted that the eruption preceded the stomatitis, and that both were insignificant in comparison with the constitutional depression. Indeed, it cannot be said that Mr. Forster ever had stomatitis; his mouth was simply congested and dry. That the eruption was in some connexion with the constitutional disturbance is a conclusion favoured by the facts of his stay at Cannes. As early as Feb. 4th he had complained of weakness after a walk, and had vomited, and from this date he had lost flesh and strength. His eruption had begun to show itself before this, and was increasing as his loss in health increased.

The necropsy was made by Dr. James Anderson and my eldest son, none of Mr. Forster's more intimate friends feeling able to be present. They were not told more than that the case was supposed to be one of typhoid, and hence the omission to examine the arm. Excepting at the visit on Sunday, however, the arm had not attracted any attention, nor had any further complaint of pain in it or elsewhere been made. The following are notes of the post-mortem as written out at the time:—

"Body bile-stained; abdomen slightly distended; yellowish from decomposition. Subcutaneous fat considerable. Lungs extremely œdematous and congested; left base almost airless. Effusion of about 15 oz. into left pleural cavity; a few ounces into the right one. Heart-muscle fairly nourished. Valves healthy. No effusion into pericardial cavity. Endocardium very much bile-stained. Abdomen: Dense adhesions of omentum and of liver to anterior abdominal walls. Tag of omentum adherent to abdominal wall in front of cæcum not recent. Some old adhesion between parts of small intestine. Considerable old inflammation in neighbourhood of gall-duct, with some recent retro-peritoneal hæmorrhage. Foramen of Winslow closed. Nothing abnormal was found in the small or large intestine, except that the wall of the latter was much sodden, but showed no ulceration. Kidneys large; capsules stripped easily; surface showed irregular congestion, and hæmorrhages with a few cysts containing blood-stained fluid. On section the cortex was extremely soft, breaking down at points, and studded with numerous milary hæmorrhages and a few as large as a pea. Pyramids congested. Changes most marked in right kidney. Liver bile-stained and fatty; no hæmorrhage; no evidence of distension of ducts; no calculi in gall-bladder. Spleen large, dark, and of medium consistency.

(Signed) "JAMES ANDERSON, M.D.
"JONATHAN HUTCHINSON, JUN., F.R.C.S.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—At the thirty-seventh annual meeting of the governors of this institution on the 9th inst., it was reported that the number of in-patients treated during the past year amounted to 1908, as against 1899 in the preceding year; the number of out-patients was 11,778. The income amounted to £7150.

NEW MEDICAL SOCIETIES IN RUSSIA.—Two new Medical Societies have recently been started in Russia. One is for the study of syphilis and dermatology, and has already met several times, the president being Prof. B. Tarnovski, and the vice-president Prof. Polotebnoff. The other, devoted to ophthalmology, is in process of formation.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

River Tyne Port.—The reports from this port district afford an excellent example of systematic sanitary work, and of a state of preparedness for such emergencies as may arise in an important port. No less than 13,530 vessels were inspected, and structural improvements were ordered to be carried out in 330 cases. Amongst the vessels entering the port were 563 coming either directly or indirectly from ports infected or suspected of cholera, and exceptional care was exercised with regard to these, especially with reference to the question of water-supply. A new floating hospital is being erected in the port to replace the existing one, which is, by reason of old age and otherwise, becoming insufficient for the purposes of the district, and during 1885 eleven patients, all of whom recovered, were placed under isolation. On the whole Mr. Henry Armstrong's report is a very satisfactory one.

Bedford Urban District.—Notwithstanding a severe fatality from whooping-cough and from measles, the death-rate for this borough was slightly under 18 per 1000 during 1885; the deaths under one year being at the rate of 153 per 1000 registered births. The zymotic rate was heavy, reaching as it did 3·9 per 1000. Small-pox was introduced into the town, but by the aid of vaccination and isolation in hospital it was checked. Bedford is by no means free from the anti-vaccination movement, and hence Dr. Prior advises his readers to study the story told in the last report of the Medical Officer of the Local Government Board about the prevalence of small-pox in Kilmarnock in the last century. Such a study should suffice to show what small-pox was before the introduction of vaccination. He also refers to the experience of Leicester as inapplicable to Bedford, on the ground that in the former town the authorities go beyond the provisions of the law and quarantine all households in which a case of small-pox may appear. We may add to this that deaths from small-pox in the Leicester hospital are not registered as occurring in the borough, but in a totally different district, where the hospital is situated. Diphtheria, which has by no means given up its hold on this neighbourhood, caused ten deaths, and Dr. Prior promises to discuss the subject in a separate report. It is satisfactory to note that the phthisis death-rate was during 1885 the smallest recorded for twenty-five years. Considerable improvements are in progress in connexion with the public water service, and a large amount of valuable sanitary work continues to be carried out in the district.

Shipley Urban District.—Mr. Ellis reports that 22 isolated cases of scarlet fever occurred, and he points out that it is by no means an easy thing to prevent the spread of this disease in a district where so many children are massed together in public elementary schools. This we admit, especially where means of isolation are not resorted to, and it seems curious that the report proceeds to state that no cases of infectious disease arose necessitating removal to the Fever Hospital. But with the aid of the school authorities the results appear to have been fairly satisfactory. The general sanitary circumstances of the town are, according to Mr. Ellis, in a satisfactory state, the record of the inspector of nuisances is a good one, and the death-rate for 1885 was 16·2 per 1000 living.

Guisborough Combined District.—Small-pox was imported into Guisborough during the course of the year reported on, and no provision being made by the sanitary authority for the isolation of first cases of infectious diseases, the infection spread from three centres and became epidemic, no less than 42 houses and 130 persons being attacked. At Loftus, on the contrary, the same disease was at once isolated, and no spread resulted. The birth- and death-rates for 1885 were 35·0 and 17·7 respectively. The death-rate had varied from 13·9 in the Saltburn urban district to 19·0 in the Skelton and Britton district.

Ashton-in-Makerfield Urban District.—Scarlet fever was almost continuously present in this district during the past year, the disease having commenced in the previous year. The deaths which resulted were 24 in number, and Mr. Hannah states that the usual preventive measures were adopted. The only hospital then available seems to have been a temporary one, which stood in much need of repairs, and it is not stated whether it was used or not during the epidemic. We fear not, for in February, when scarlet fever was already fatally prevalent, we learn that the hospital was "dispensed with." But a new hospital is apparently approaching completion, and better success in the direction of prevention may therefore be anticipated in the future. The general death-rate was 21·6 per 1000.

Holsworthy Rural District.—This rural district has, in parts, an unnecessarily high death-rate, it being in excess of that for England and Wales, and that for Holsworthy parish reaches 25·6 per 1000. Mr. Linnington Ash has often advised the provision of means of isolation, and in pointing out how small-pox, when once imported, spread amongst a crowded aggregation of navvies, he disclaims all responsibility for the untoward result. Not even a barn could be procured for the isolation of the first case, and yet no provision was made in advance. Then a temporary hospital was erected, which, if precedent be followed, will prove all but useless for further emergencies. In all, the epidemic cost over £300. Further improvements have been carried out as regards the water-supply of the district, but in Holsworthy itself the supply available cannot be regarded as meeting the requirements of the place. A good deal of routine sanitary work is in progress, and the report is made very complete by the addition of a number of excellent statistical tables, which must have considerable local interest.

Stroud Rural District.—Enteric fever at Stonehouse is referred to in this report, and it is lamentable to read of the loss of valuable lives there, when all that was needed to prevent the loss was prompt action in the directions indicated by the medical officer of health. Mr. Partridge shows conclusively how great is the need of improved water-supplies in various portions of the district. That of Painswick is chiefly from polluted wells, although this has been reported before. At Horsley matters are much the same, whereas a good supply is allowed to run to waste. It seems, in short, evident that there is something very wrong in this matter of water-supply, and that risk of disease and death is in consequence imminent. If this further report fails to move the sanitary authority to energetic action, the case is one in which the inhabitants should consider whether they would not do wisely to make a definite complaint of default under Section 299 of the Public Health Act, 1875.

Thingoe Rural District.—From this report we gather that, both as regards the prevention and extension of disease and in the matter of providing permanent remedy for nuisances calculated to injure health, steady work is continuously carried out. Mr. Kilner is, however, very naturally not content with some of the means of drainage which lead to the pollution of the river, but a line of action tending to diminish the resulting evil has been adopted. The birth- and death-rates for 1885 were 27·2 and 15·2 per 1000 respectively.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5485 births and 4630 deaths were registered during the week ending March 6th. The annual death-rate in these towns, which had been equal to 24·4 and 24·2 per 1000 in the preceding two weeks, further rose last week to 26·6, and exceeded the rate recorded in any week since March, 1883. During the first nine weeks of the current quarter the death-rate in these towns averaged 23·5 per 1000, and was 1·0 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 17·9 in Brighton, 18·0 in Hull, and 20·4 in Oldham. The rates in the other towns ranged upwards to 34·0 in Preston, 34·6 in Wolverhampton, 35·4 in Plymouth, and 36·4 in Blackburn. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 425 and 385 in the previous two weeks, rose again last week to 403; they included 171 from whooping-cough, 101 from measles, 42 from diarrhœa, 31 from "fever" (principally enteric), 28 from scarlet fever, 27 from diphtheria, and 3 from small-pox. No death from any of these zymotic diseases was recorded last week in Wolverhampton; whereas they caused the highest death-rates in Portsmouth, Bolton, Plymouth, and Blackburn. Whooping-cough caused the greatest mortality in Plymouth, London, and Portsmouth;

Digitized by Google

measles in Bolton, Plymouth, and Blackburn; scarlet fever in Birkenhead; and "fever" in Cardiff. The 27 deaths from diphtheria in the twenty-eight towns included 19 in London and 5 in Liverpool. Small-pox caused 3 deaths among the residents of London, 2 in Liverpool, and 1 in Brighton, and not one in any of the twenty-five other large towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 10 and 15 on the preceding two Saturdays, had declined to 7 at the end of last week; and no new case was admitted to these hospitals during the week, the admissions in the preceding two weeks having been 2 and 7. The deaths referred to diseases of the respiratory organs in London, which had increased in the preceding six weeks from 477 to 677, further rose last week to 745, and exceeded the corrected weekly average by 294. The causes of 96, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Plymouth, Derby, and Birkenhead. The largest proportions of uncertified deaths were registered in Sheffield, Oldham, Halifax, and Bolton.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 22·3 and 23·5 per 1000 in the preceding two weeks, further rose to 24·9 in the week ending March 6th, but was 1·7 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 17·1 and 17·4 in Aberdeen and Dundee, to 25·2 in Paisley, 30·1 in Glasgow, and 31·1 in Perth. The 614 deaths in the eight towns showed a further increase of 34 upon the numbers in the previous two weeks, and included 19 which were referred to whooping-cough, 7 to "fever" (typhus, enteric, or simple), 7 to diarrhœa, 4 to scarlet fever, 3 to diphtheria, 3 to measles, and not one to small-pox; in all, 43 deaths resulted from these principal zymotic diseases, against 46 and 51 in the preceding two weeks. These 43 deaths were equal to an annual rate of 1·7 per 1000, which was 0·6 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 13 and 19 in the preceding two weeks, were again 19 last week, of which 17 occurred in Glasgow. The 7 deaths referred to "fever" showed a slight further increase upon the low numbers in recent weeks, and included 4 in Glasgow. Three of the 4 deaths from scarlet fever, 2 of the 3 from diphtheria, and all the 3 from measles, were returned in Glasgow. The 7 deaths attributed to diarrhœa, of which 3 occurred in Edinburgh and 2 in Glasgow, were 2 below the number in the corresponding week of last year. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had increased in the preceding four weeks from 135 to 159, further rose last week to 170, and exceeded the number in the corresponding week of last year by 51. The causes of 73, or more than 11 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 38·6, 31·8, and 30·4 per 1000 in the preceding three weeks, further declined to 30·1 in the week ending March 6th. During the first nine weeks of the current quarter the death-rate in the city averaged, however, no less than 32·0 per 1000; the mean rate during the same period did not exceed 23·9 in London and 18·3 in Edinburgh. The 204 deaths in Dublin last week showed a further decline of 2 from the numbers returned in the preceding three weeks, and included 15 which were referred to the principal zymotic diseases, against 26, 20, and 22 in the previous three weeks; 10 resulted from whooping-cough, 4 from "fever" (typhus, enteric, or simple), 1 from diarrhœa, and not one either from small-pox, measles, scarlet fever, or diphtheria. These 15 deaths were equal to an annual rate of 2·2 per 1000; the rates from the same diseases being 2·8 in London and 1·6 in Edinburgh. The fatal cases of whooping-cough, which had been 16 and 18 in the previous two weeks, declined last week to 10. The 4 deaths referred to "fever" showed an increase of 2 upon the number returned in each of the two previous weeks. Five inquest cases and 4 deaths from violence were registered, and 60, or nearly a third, of the deaths were recorded in public institutions. The deaths of infants showed a decline, whereas those of elderly persons were more numerous than in either of the preceding two weeks. The causes of 17, or more than 8 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon-Major Hopetoun Currie Collier is granted retired pay, with the honorary rank of Brigade Surgeon.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Inspector-General of Hospitals and Fleets Henry Fegan, C.B., M.D., has been placed on the retired list.

The following appointments have been made:—Fleet Surgeon Henry Hadlow, to the Royal Naval Hospital, Chatham; Surgeon Arthur W. Russell, to the *Hyacinth*; Surgeon Horatio S. R. Sparrow, to the *Polyphemus*; Surgeon Henry A. W. Richardson, to the *Osprey*; Surgeon Evan St. M. Nepean, to the *Triumph*; and Surgeon William W. Jacobs, to the *Royal Adelaide*.

RIFLE VOLUNTEERS.—1st Volunteer Battalion (the Duke of Cornwall's Light Infantry): Honorary Assistant-Surgeon Andrew Harvey resigns his commission.—2nd Renfrewshire: James Tomlins, Gent., to be Acting Surgeon.—3rd Volunteer Battalion (the South Staffordshire Regiment): Surgeon John Fraser, M.D., is granted the honorary rank of Surgeon-Major.

"Audi alteram partem."

DEATH FROM CHLOROFORM.

To the Editor of THE LANCET.

SIR,—I beg to forward you particulars of the recent death here from chloroform. The Lady Flora Wilmot, aged twenty-five years, had been under my care for various minor ailments during the last eighteen months. With the exception of a gouty tendency, her constitution was, I believe, sound. On Wednesday, Feb. 24th, I was asked to meet her at Mr. Scott's residence at Swansea (her dentist) for the purpose of administering an anæsthetic for the extraction of the right molar tooth. Nitrous oxide gas not being available, I gave chloroform in preference to bichloride of methylene or ether (both of which I had by me), because for the purpose I considered it the best anæsthetic, and also because her ladyship, having taken it two or three times before, expressed a preference for it. Everything about the chest being perfectly loose, and the patient sitting in the dentist's chair, less than a drachm was sprinkled on lint in an open inhaler, which the gag kept from closely fitting round the mouth and nose. A similar quantity of chloroform was added a second and third time before perfect anæsthesia occurred. The tooth was then removed, and recovery followed without a bad symptom. The patient had taken it capitally, and in all two drachms had been given. Five days afterwards (March 1st) I again administered chloroform for Mr. Scott (this time at the patient's residence) to remove the adjoining bicuspid tooth. The patient was seated in a low deep-backed well-pillowed easy chair, and was therefore more reclining than on the former occasion. The result of the chloroform before having been so satisfactory, I again administered it in the same way, and, as before, two drachms were given in all, with a similarly good result. The inhaler having been removed, Mr. Scott took out the tooth, cleaned his forceps, and stood by the patient's side. I remarked, "I hate giving chloroform for you dentists because you will have your patient sitting up." This led to a reply from Mr. Scott, who then poured out a tumblerful of water and asked the patient to rinse her mouth, as the gums were bleeding. No water was taken, and I observed she was not sufficiently conscious yet, and we still stood by the patient. I had during this time one finger on the temporal artery, whilst with the other hand I was raising the eyelid and watching the pupil, which, having been dilated during unconsciousness, had become normal and the conjunctiva sensitive. Suddenly the pupil became

Digitized by Google

again widely dilated, I could no longer feel the pulse, and the face became blanched. The chair was immediately turned back, the head lowered to the ground, and the body and limbs raised. Nitrite of amyl sprinkled on a handkerchief was applied to the nose, and, although the heart could not be felt beating, the breathing still continued for, I should say, at least two minutes. Artificial respiration, drawing out the tongue, and lifting the jaw forward, were of no avail—not the slightest sign of recovery followed. A post-mortem examination was refused. Yours obediently,

Swansea, March, 1886. J. FARRANT FRY.

THE ETIOLOGY OF PROSTATIC ENLARGEMENTS.

To the Editor of THE LANCET.

SIR,—In an interesting communication by Mr. Reginald Harrison upon the above subject in your issue of the 6th inst., we read that he believes a depressed trigone permits the accumulation of residual urine, induces the hypertrophy of the inter-ureteral bar, and thus is the immediate cause of prostatic hypertrophy. He states further that this hypertrophy is localised to the vesical floor, and contrasts its limited area with the general hypertrophy following stricture. I would ask, Is it physiological that a hollow muscular viscus under the control of one definite centre (Budge, Gianuzzi) can contract so often in a limited section of its small area so as to produce hypertrophy of that section, and of that alone? Again, I would submit that the inter-ureteral bar is mostly made up of muscle bundles derived from the sides and back of the bladder itself. Is it reasonable to suppose that one part of those bundles can hypertrophy without a similar change in the remainder of those bundles? I would mention that in an examination of over 400 fresh bladders I have never met with hypertrophy of the inter-ureteral bar either in prostatic enlargement, stone, or stricture, unless there was a coexisting and corresponding hypertrophy of the entire viscus. But a theory like that on which I thus venture to comment, emanating from one so well known as Mr. Reginald Harrison, upon a subject so controversial and so important, demands serious consideration and discussion. He would be conferring a real benefit upon his London *confrères* were he to bring forward his views, and the specimens upon which he mentions they are based, at the Pathological Society.—I remain, Sir, faithfully yours,

E. HURRY FENWICK.

George-street, Hanover-square, W., March, 1886.

INVERSION OF THE UTERUS.

To the Editor of THE LANCET.

SIR,—Dr. Barnes, in THE LANCET of Feb. 27th, appears to resent my remarks in a previous number, where I endeavoured to show that incision of the os previous to reducing an inverted uterus had been practised before 1868. Dr. Pratt, in the *Medical Times and Gazette*, thus writes in March, 1868, when speaking of the operation referred to above:—"This mode of treatment is not new, although not mentioned by Murphy, &c.....but Dr. Wassiege of Liège says that it is the only legitimate, as it is the most effective, plan." This, I think, proves that the operation must have had an established reputation abroad before 1868, the date of Dr. Barnes' first operation. Certainly, I had no wish, nor could I succeed if I had, to detract from Dr. Barnes' high merits, and I feel rather aggrieved that the "valuable" Digest should be described as referring chiefly to "three medical journals." Had it fallen to the fate of Dr. Barnes to keep up the Digest, week by week, month by month, and year by year, he would soon have discovered that it embraced, in addition to the "three principal medical journals," seven or eight others, which secures a reference to every subject, either in English or foreign literature, that is of practical value to the medical profession.

I am, Sir, yours faithfully,

RICHARD NEALE, M.D., Lond.

Boundary-road, N.W., March 3rd, 1886.

THE South Hornsey Local Board are endeavouring to obtain from the Ecclesiastical Commissioners their interests in Crissold Park, with a view to its preservation as an open space for the use of the public.

MANCHESTER.

(From our own Correspondent.)

OWENS COLLEGE.

AT the half-yearly meeting of the Court of Governors of the Owens College, held on the 2nd inst., it was reported that satisfactory progress was being made with the work of extension of the College buildings, which has been going on for the past two years, and that the Coupland-street block will be ready for use at the beginning of the session 1886-7, and the museums will be ready for the reception of the collections in natural history and geology in the spring of 1887, and thus be complete prior to the visit of the British Association in that year. The façade to Oxford-road presents an imposing appearance, and the tower, now almost completed, stands out a commanding landmark for a considerable distance round, while within the grounds the quadrangle which will be formed when the entire plans are carried out is complete on three of its sides. The report stated that there were at present a total of 1244 students in the various departments of the College. The Council had accepted with much regret the resignation of Sir Henry Roscoe as Professor of Chemistry, owing to his recent election as member of Parliament for the southern division of the city. It was resolved to establish an engineering laboratory in the College, at a cost of £6000.

SIR WILLIAM ROBERTS.

The meetings of the Medical Society are not often graced with the presence of Sir William Roberts, but on Wednesday last he gave a very interesting *resumé* of some experiments he had made upon the solubility of gouty deposits (the bi-urate of soda) in various solutions of soda, potash and lithia salts. As usual with him, the work was on the scientific side of medicine, and yet not without a direct bearing upon the practice of the same. Sir William has been much more before the public the last few days than is his wont; on Monday last he was presiding at the annual Welsh dinner held on St. David's Day, and on Saturday a complimentary dinner was given to him on the celebration of the honour of knighthood recently conferred upon him. Dr. H. Simpson was in the chair, and most of the leading members of the profession in the town and districts were present, amongst the visitors being Dr. Buchanan of the Local Government Board.

PROVIDENT DISPENSARIES.

At the annual meeting of the Provident Dispensaries it was stated by the chairman that 20,000 persons had joined these institutions, and thus had been rescued from going begging to medical charities, and also as a result of ten years' work the proportion of persons seeking gratuitous medical attendance at our hospitals who were in a position to pay for the same had been reduced from 42 per cent. to 12½. The subscriptions of members had amounted during the past year to £3560, of which £2000 had been paid to the medical staff. Thus much from the provident dispensaries' point of view; but there have been several communications during the past few days from medical men and others tending to show that, if they have been the means of preventing abuse of the hospitals, the dispensaries themselves are not altogether without reproach, seeing that no limit is placed upon the income of those entitled to join them; and that, as a matter of fact, many do join who are well able to pay the ordinary medical fees charged to the working classes, and thus great injustice is done to those members of the profession whose work is perhaps the heaviest, and certainly the worst paid.

LOCAL MEDICAL CHARITIES.

A very interesting little *brochure* has lately been printed by the Infirmary Committee relating to one of its allied branches — the Barnes Fever Hospital, — compiled by Dr. Renaud, formerly one of the physicians to the institution, and now consulting physician to the infirmary. He briefly traces its history, from the formation of the first fever house in 1796, through all its various changes down to the present time. Much of the history consists of personal reminiscences, and well deserves the permanent record thus given to it. The last additions to this hospital have but recently been finished, consisting of two new blocks of wards and a large nurses' home, the latter of sufficient size

Digitized by Google

to accommodate fifty inmates, the total cost of these extensions being something like £10,000, and still further outlay is, it is understood, shortly contemplated. At another branch of the infirmary—the asylum at Cheadle—the completion of the extensions of the buildings were celebrated on the 25th ult. by a fancy dress ball, at which, in addition to all those of the patients who were fit to mix together, a number of invited guests, including several members of the staff, were present. The dancing took place in the handsome new recreation-room, which was prettily decorated, and the whole scene was one of exceptional brilliancy. The Hospital for Consumption is advancing each year in importance and in the amount of work done by it. At the annual meeting, in common with all the other charities, the committee ask for increased support to meet additional expenses, and appeal for an increase of no less than £1000 per annum for working expenses. The committee has been fortunate in obtaining the services of Dr. Simpson and Mr. Hardie as physician and surgeon respectively in place of Dr. Gamgee and Mr. Young, who have resigned during the past twelve months. The total amounts received from the Hospital Saturday and Sunday Funds so far are £6751—a sum below last year's collections; but this may be increased considerably yet, as the whole of the contributions have not yet come in.

Manchester, March 8th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE CHILDREN'S HOSPITAL: MUNIFICENT OFFER.

THE annual meeting of the above hospital was held lately, under the presidency of Sir W. G. Armstrong, C.B. The report stated that the number of in-patients treated had been 138, as compared with 156 in 1884; the decrease in the number was due to the fact that the hospital had been twice cleared of its inmates during the year, on one occasion owing to an outbreak of measles, and once during the summer to allow of the repainting and cleaning of the whole building. The number of out-patients was 2483, as compared with 2087 in 1884. It was stated in the medical report that the 2483 out-patient cases involved 7000 separate consultations by the physicians or surgeons. Mr. John Fleming, a governor of the hospital and a solicitor in this city, in moving the adoption of the reports, referred to the unhealthy situation of the hospital, situated as it is in the midst of a very poor and overcrowded population; and as a convalescent home was an acknowledged want in connexion with the hospital for the perfect recovery of the children, he had thought it would save expense if a new hospital were to be built in an airy situation, and thus combine the advantages of hospital and convalescent home in one building. He further offered to purchase a site for the new hospital, and to build and furnish it complete; and, taking into consideration the growing requirements of the city and district, he thought the new hospital should be large enough to receive from sixty to eighty in-patients. Mr. Fleming wishes to build the hospital as a memorial of his late wife, and that its erection should be at once commenced, so that the next annual meeting might be held in the new building. Mr. Fleming's munificent offer was gratefully accepted, and in the discussion which followed it transpired that the present hospital building was freehold, and might be sold at an enhanced value for business purposes, and thus augment the income of the hospital. The Children's Hospital has been in operation here for about twenty-three years, and at first began on a very small scale. Dr. William Murray and Mr. Joseph Fife were the first medical attendants. The former is in active practice as a physician here, but the latter retired a few years ago. A good deal of the popularity of the hospital has been owing to the energy with which both these gentlemen undertook the duties. It had a good start, and has never flagged since. I regret that the medical founders were not mentioned at the meeting.

OPIUM AMONG MINERS' WIVES.

According to Dr. O'Hanlon of Spennymoor, the use of opium in the mining districts of the county of Durham would appear to be on the increase. At the last meeting of the local board, in his report for 1885, he referred to the excessive use of intoxicants as being a great source of disease in the town, likewise the chewing of tobacco and the use of narcotics in the form of opium and laudanum. "Few people," he said, "were aware of the enormous consumption of opium among miners' wives; they were left at home for a long time alone and taught each other the habit."

A FOURTEEN-YEAR-OLD MOTHER.

At the Stockton Police Court a man aged forty-four was charged, under the Criminal Law Amendment Act, with assaulting Clara Wilson, aged fourteen. Lately the girl gave birth to a child, and on being questioned she stated that the defendant (who was remanded) was the father.

Newcastle-on-Tyne, March 8th, 1886.

GLASGOW.

(From our own Correspondent.)

DISCUSSION ON CANCER.

THE most important event in this session of the Pathological and Clinical Society has been the discussion on cancer. It began with a demonstration of the various forms of malignant growth, illustrated by over a hundred microscopes and numerous casts, specimens and diagrams, so arranged as to show the structure and mode of extension of cancers. The discussion proper lasted for several nights, and was carried on not only by local pathologists and surgeons, but also by some from other parts of the country, amongst whom was Mr. Jonathan Hutchinson. It forms a notable contribution to the literature of the subject.

STUDENTS' UNION.

The students of Glasgow University are remarkably fortunate in their day and generation. A movement was set on foot among them at the beginning of last year for the establishment of a union, and a committee was appointed to further the scheme. Designs for a building, consisting of a hall capable of seating 400, with smaller rooms for the meetings of affiliated university societies, have already been prepared, the estimated cost being from £5000 to £6000. The main difficulty was want of funds. This has been got over, however, and the movement has received a great impetus through the announcement, recently made, that a gentleman, whose name is in the meantime withheld, a medical graduate of the university, has promised a sum of money sufficient to defray the cost of erecting the building. Generosity of this kind is as commendable as it is rare. One point which is much discussed among the students has reference to the site most appropriate for such a building. There is a pretty general feeling in favour of some situation more central than the university grounds, one nearer the localities where the majority of the students live, for the Scotch students, unlike English university students, do not reside in college.

DR. B. W. RICHARDSON'S VISIT.

Glasgow has recently been favoured with a visit from Dr. B. W. Richardson, made under the auspices of the British Medical Temperance Association. In the course of his visit he delievered two lectures. In the first of these, a public lecture, Dr. Richardson discoursed eloquently on the progress of sanitary science even during his own lifetime, and on the part which temperance played as a sanitary measure. The picture he drew of a town ideally perfect in sanitary matters, with its comparative freedom from disease, its low death rate (9 per 1000), and the long duration of life therein (105 years it ought to be), ended by a peaceful and painless process of euthanasia, were very striking; and no less striking was the picture he drew of the effect on such a community of the introduction of intemperance in the use of alcoholic liquors. His second lecture was to students, and dealt with the more scientific and medical aspects of the action of alcohol. While condemning the use of alcoholic liquors as beverages, he claimed and affirmed the right of the physician to use alcohol as occasion demanded in the treatment of disease.

Glasgow, March 9th, 1886.

THE first annual meeting of the subscribers to the Portsmouth Eye and Ear Infirmary was held on the 23rd ult., when a highly satisfactory report was presented by the committee.

IRELAND.

(From our own Correspondent.)

DUBLIN HOSPITALS COMMISSION.

LAST week Mr. Thomson, one of the surgical staff of the Richmond Hospital, gave some very valuable evidence before the Commissioners, bearing on the subject of the proposed amalgamation of certain of the Dublin hospitals. He stated that he was entirely in favour of the principle of amalgamation in Dublin, and considered that the Richmond, Whitworth, and Hardwicke ought to be amalgamated with Steevens's Hospital, and a new building erected in the neighbourhood of Christchurch-place. Dublin, he believed, had too many hospitals as compared with its population of 250,000, having ten general hospitals and 919 beds occupied. In Liverpool, with 552,000 inhabitants, there are only four general hospitals and 613 beds; in Manchester, with a population of 393,000, two hospitals, with 440 beds; in Birmingham, with a population of 400,000, two hospitals and 440 beds. On all the hospitals £85,000 a year is spent, including the special institutions, while only £27,400 of that money goes to the maintenance of the patients. It follows that Dublin is over-hospitalled and over-medical-officered. In Mercer's Hospital, for 45 beds there are three surgeons and two physicians, or 9 beds to each; in the Meath, with 85 beds, with a staff of eight, there is an average of 10½ beds each; in Jervis-street, with 25 beds, there are seven surgeons and two physicians, or less than 3 beds each, or, taking 150 beds for the latter institution, 15 beds to each medical officer. In the House of Industry Hospital, with 150 beds and a staff of eight, there is an average of 19 beds; and in the Mater Misericordiæ an average of 27. Mr. Thomson thought that 1200 beds divided over four hospitals would be ample, and was of opinion that the money would be got partly from the grant and partly from the public. He would put the Mater Misericordiæ on one side—it was a sectarian hospital, was not in debt, and should not receive a share of the grant, being managed in the interests of a particular church; he objected also to the nursing being in the hands of any sisterhood. No doubt the advantages of amalgamating certain of the Dublin hospitals is manifest; but with an over-officered medical staff as exists at present, the difficulty would be as to which of the medical officers in each institution amalgamated should retire, and whether they would be entitled to any compensation for the share of the students' fees they at present receive. The subject is a difficult one, and a solution of the matter would be desirable in the interests of all concerned.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

Some time since, the President of the College, Sir Charles Cameron, suggested that the College ought to elect some honorary Fellows from amongst distinguished surgeons, as the existing honorary Fellows were, with one or two exceptions, military or naval medical men. This suggestion has been carried out, for at the last meeting of the Council they unanimously elected as Honorary Fellows the following:—M. Pasteur of Paris, Sir James Paget, Bart., Sir Joseph Lister, and Professor Huxley. The President, I am informed, intends giving a banquet in the College on April 28th, on the occasion of the unveiling of the Dease statue and the opening of the Butcher Museum, and his Excellency the Lord-Lieutenant has accepted the President's invitation to the banquet. It is hoped that some of the newly elected Honorary Fellows will be able to be present on this interesting occasion. The Council will next week elect a Curator of the Museums of the College, at a salary of £250 per annum, in the vacancy caused by the retirement of Mr. Abraham.

ROYAL UNIVERSITY OF IRELAND.

A meeting of Convocation of the Royal University of Ireland will be held on the 6th prox. to elect a member of the Senate in the vacancy which will then occur. Mr. Farrelly, whose term of office expires, will, it is expected, be a candidate for re-election, and will be opposed by Mr. Wm. Thomson, surgeon to the Richmond Hospital.

STUDENTS' AMBULANCE CORPS, BELFAST.

The first general meeting of the members was held last week in Queen's College, Belfast. The chairman having explained the objects of the meeting—namely, to elect a committee and two secretaries *pro tem.*, to organise the corps and make all necessary arrangements,—an election was held for office-bearers. It is stated that upwards of 100 students of the College have joined, and it is expected that drill and training will commence early in the summer.

A life-size portrait of Sir Charles A. Cameron, M.D., the President of the Royal College of Surgeons in Ireland, was last week presented to the Grand Lodge of Ireland by the members of the Masonic Lodge 25, of which Sir Charles Cameron is the efficient secretary.

Deputy Surgeon-General John Madden died at his residence, Rutland-square, on the 8th inst.

Thomas Barker, M.D., of Castleview House, Carlingford, has been placed on the Commission of the Peace for the County Louth.

The late Mr. P. A. Smith bequeathed a sum of £200 to each of the following charitable institutions:—Mater Misericordiæ, Vincent's, Mercer's, Sir P. Dun's, Jervis-street, and Coombe Lying-in Hospitals. The City of Dublin Hospital has also received £100.

Dublin, March 8th.

PARIS.

(From our own Correspondent.)

PTOMAINES AND THE MICROBE THEORY.

AMONG the conclusions formulated by the various speakers who have taken part in the debate at the Academy of Medicine on the pathogeny of disease, those enunciated by Professor Verneuil seem to me the most admissible, as they are the most plausible. In response to the speakers who preceded him, M. Verneuil stated that he recognised two principal origins of general maladies: 1. The invasion by germs which penetrate into the organism from without, and which had their existence in cosmic media. 2. The contamination of the interior of the organism by waste tissues resulting from diminished, augmented, or perverted nutrition. In other words, the learned Professor adopts all which appears to him clearly demonstrated in the microbian theory, or in the theories borrowed from pathological physiology and biological chemistry. As regards the *rôle* of the organism itself in the manufacture of disease, no one perhaps more than M. Verneuil has directed attention to that subject—that is to say, the intimate connexion that exists between a disease-germ and the body which receives it, which is the constitutional states of pathologists. For diseases of physiological origin, the organism no doubt plays the principal *rôle*. For nosological or microbian diseases, the economy is reduced to accept, submit to, multiply or destroy, refuse or reject the germs, without being able of itself to create a single one at any time or in any condition whatsoever. Thus, Professor Verneuil does not in any case admit morbid spontaneity—that is, in the grammatical sense of the word,—as the alterations in *plus* or in *minus* of nutrition are never produced by themselves, which necessarily imply causes on the one hand and pathological specificity on the other; the latter would imply the existence in an absolute manner of beings altogether distinct from those which they invade, and this would lead to the conclusion that there cannot exist at the same time spontaneity and specificity.

DEATH OF DR. BOCHEFONTAINE.

I regret to have to report the death of Dr. Bochefontaine, chief of the laboratory of the Faculty of Medicine of Paris and of the Hôtel Dieu. His death is considered a great loss to science, as he was an indefatigable searcher for biological facts. He was an avowed adversary of the microbian theories, particularly those professed by Pasteur and Koch; and it will be remembered that he was so convinced of the non-contagiousness of cholera that during the epidemic of last year he swallowed a pill composed of the dejections of a cholera patient, and consequently some millions of the comma bacilli, from which he suffered no other inconvenience than a slight malaise. He was latterly engaged in some important researches respecting the real efficacy of M. Pasteur's anti-rabic inoculations, when death overtook him after an illness of three weeks. As he was a most daring experimenter, even upon his own person, it was bruited about that he had fallen a victim to some experiment. The fact is that he had been, as just stated, ill for

Digitized by Google

about three weeks, suffering from abscesses in the throat and jaws, resulting from decayed teeth, which ended in fatal periostitis. He was only forty-five years of age.

REPORT ON SUICIDES.

The official report on suicides for the Department of the Seine for the year 1885 gives the following results:—There were 642 suicides or attempts at suicide from January 1st to December 31st. During the preceding year there were 542. Firearms were the principal means adopted, of which there were 225 cases; of these there were 160 for Paris alone and 65 for the rest of the Department. There were 150 suicides by drowning, 88 by hanging, and 142 by asphyxia; the others were effected by precipitating themselves from windows, monuments, &c; 62 were effected by crushing or by poisoning. The principal causes assigned are reverse of fortune, failure in business, dissipated living, particularly when accompanied with the use of alcohol. Several cases of self-destruction occurred among youths, principally among collegians, and the causes given display a high degree of mental precocity or immoral training.

PROPOSED HEALTH EXHIBITION.

An exhibition of everything concerning hygiene is being organised by the Society of Public Medicine at Paris, and is to take place in the month of May next in a large building at the back of the Hôtel de Ville. This exhibition, exclusively of a scientific and technical character, will comprise all plans and models of constructions and of apparatus destined to ensure the salubrity of the ground floor, underground rooms of private habitations, of cheap houses, and public buildings, such as schools, hospitals, and asylums, theatres, meeting or lecture rooms, &c. The exhibition is placed under the patronage of the members of the institute, and of the Academies of Sciences and of Medicine, and also of the Government.

THE TREATMENT OF HYDROPHOBIA.

A commission appointed by the Academy of Sciences has decided upon the establishment of a *locale* in Paris for the treatment of persons bitten by mad dogs. It is to be called "Institut Pasteur," and is to be supported by public subscription. As it is intended to be international, subscriptions are solicited from all parts of the world.

Paris, March 10th, 1886.

NEW YORK.

(From our own Correspondent.)

QUARANTINE.

THE health officer of New York quarantine is paid by fees, the charge for each vessel being $6.50. The total fees per annum are believed to vary from $60,000 to $100,000. There is a movement in the Legislature to abolish the fee system and give him a salary of $10,000. The discussion has brought to light some interesting facts. In 1880, 7827 vessels entered this port, and the receipts of the health officer were $64,000, and of this sum $25,000 were paid for running expenses, leaving a net income of $39,000. In 1885, 5908 vessels arrived, being nearly 2000 less than in 1880, and making a diminution of over $12,000 in the emoluments of the office. If these statements are true, the office is not now so lucrative as has been supposed, for, being a political office, the party in power always lays the health officer under heavy contribution.

THE BOARD OF HEALTH.

The New York Board of Health has been one of the most reputable bodies in the Senate until recently, when its management fell into the hands of the politicians, and now its president is under indictment by the grand jury for receiving bribes for official acts. On his trial the jury stood eleven for conviction and one for acquittal. The effect of the change of administration is visible in every department of the service: officers have been multiplied, salaries incurred, and the duties have been performed with less and less vigour. Public confidence has been very much lessened by the scandal.

DR. ALFRED C. POST.

The death of Dr. Post, President of the Faculty of the University Medical College, at the age of eighty, removes from medical circles a most familiar figure. For half a century he was one of the most active surgeons of this city, and he did not relax in his work until the last week of his life. He seldom failed in his attendance at the meetings of the medical societies, and always took a very lively interest in subjects under discussion. He was as much gratified with every step in advance in surgery as the younger surgeons, and never grew old in the usual way of discarding without trial "new-fangled notions."

YELLOW FEVER INVESTIGATIONS.

A Bill has been introduced into Congress to provide for the appointment by the President of a Commission to proceed to Brazil to investigate the alleged discovery of a method of inoculating for yellow fever. Few physicians have any faith in the professions of Dr. Domingos Freire, and the Bill receives support only from medical officers of the southern quarantines, and especially that of New Orleans

SUDDEN DEATH OF EMINENT MEN.

There have been many sudden deaths of eminent men recently, and the subject is attracting the attention of medical men. Calfax, a former vice-president of the United States, fell dead in a railroad depôt while on a lecture tour. Hendricks, the Vice-President under the present administration, was recently found dead in his bed. And now comes the news of the death of John B. Gough, the temperance orator, who fell, with his arms raised, in the midst of a speech. General McClellan recently died suddenly, but he had been suffering occasionally from angina. Heart disease has proved to be the chief cause of these deaths.

New York, Feb. 22nd.

ROYAL COLLEGE OF PHYSICIANS.

AN extraordinary Comitia of the College was held on the 11th inst., Dr. J. W. Ogle, Vice-President, in the chair. Certificates in Hygiene were granted to Edgar English and John Frederick Williams, who had passed the required examination.

A report was read from the Council upon Dr. West's proposals to form Standing Committees of the College to deal with professional and public matters in which it was desirable that the College should take action. The Council advised the College not to assent to these proposals, the existing system of the appointment of Select Committees whenever occasion arise being quite adequate to the purpose. After a prolonged debate it was finally decided to adjourn the discussion to the next meeting.

A report was read from the Committee of Management of the Examining Board in England, advising: (1) The omission of Medical Botany from the curriculum; (2) an option to candidates of taking Materia Medica and Pharmacy either as part of the First or as part of the Second Examination, and the permission to candidates to avail themselves at once of these alterations. Considerable discussion arose upon this report, and the synopsis of Materia Medica and Pharmacy, but the report was finally accepted without alteration.

ROYAL COLLEGE OF SURGEONS.

AT an ordinary meeting of the Council of the College, held on the 11th inst. the minutes of the last meeting were confirmed. The death of Mr. Cooper Forster was announced to the Council, and a unanimous resolution of condolence with Mrs. Forster and her family was passed. A resolution was passed to inform William Turnbull of his removal from being a member of the College owing to his conviction for manslaughter, the usual notice to be sent to the Medical Council.

The report of the Committee on the mode of obtaining the Fellowship of the College was received, and the two methods proposed by them adopted.

"In one of these the Council would elect to the Fellowship, every year, a certain number, not exceeding ten, of Members of the College, of not less than twenty years' standing, who are distinguished by scientific or professional ability, or by good service rendered to the profession or the public, and who are recommended by ten Members of the College, of whom at least half shall be Fellows, none of the Fellows so recommending being members of the Council.

Digitized by Google

"In the other method, Members of not less than fifteen years' standing would be exempted from the First Professional Examination for the Fellowship—that, namely, in Anatomy and Physiology,—and would be required to pass only the Second Examination, as defined in the Regulations for the Fellowship."

The following was also adopted by the Council:—

"That the Council should acquire the power of electing two persons, who shall be considered and named Honorary Fellows of the College, and who, whether Members of the College or not, should be persons who have rendered distinguished service in the advancement of surgery or the sciences allied to surgery. The Honorary Fellows should be exempted from the payment of any fee, and should not have the right of voting for or becoming members of the Council."

The report from the Committee of Management of the two Colleges in reference to the alterations in the curriculum was read and adopted. (See report of the Royal College of Physicians, *supra*.)

The President reported the arrangements made for laying the foundation stone of the new Examination Hall on the 24th inst. The Colleges wish all branches of the profession to be represented; and after lots have been drawn for the seats at the disposal of the authorities, the tickets will be forwarded to the successful Fellows and Members; this will be the only notice of the result of the drawing. The guard of honour will be formed by the Volunteer Medical Ambulance Corps, with probably the Medical Company of the Artists' Volunteer Corps. A military band and the choir of the Savoy Chapel will be present. The Archbishop of Canterbury will open the proceedings, after which an address from the two Colleges will be delivered. Fuller details will be supplied in the programmes which will be distributed on the occasion.

The President of the College received the permission of the Council to give a conversazione in the museum during the coming summer.

Sir Joseph Lister was elected successor to the late Mr. Forster on the Committee of Management.

A letter was read from Dr. Collum, president of the Association of Members, forwarding a resolution of the Central Committee of the Association, expressive of the intention of the Association to resist the proposal to largely increase the number of Honorary Fellows.

The Council proceeded to the consideration of the motion brought forward by Mr. Macnamara on January 14th last, which had been postponed, and he moved his resolution in the following altered form:—

"That the Fellows be requested to state if in their opinion it is desirable to extend to Members of the Royal College of Surgeons the right to vote at the annual election of Fellows as members of the Council."

This was seconded by Mr. T. Smith, but lost by 16 to 4.

Mr. Marshall gave notice that he would propose a resolution at the next meeting of the Council, in reply to the resolution adopted by the Fellows and Members who were present at the meeting held on December 17th last.

MEDICAL NOTES IN PARLIAMENT.

Overhead Wires.

IN the House of Commons, on the 4th inst., in reply to Mr. M'Iver, Mr. J. Collings stated that the Local Government Board had no doubt that if a measure were brought in dealing with overhead wires, powers would be conferred on urban sanitary authorities to make bye-laws or regulations with respect to such wires for the protection of life and property.

Water-supply &c. Bill.

On the 5th inst., on the order for resuming the adjourned debate on the motion for the second reading of this Bill, Mr. Broadhurst stated that since the adjournment of the debate the hon. baronet (Sir J. McGarel Hogg) who was in charge of the Bill had agreed that he would in committee omit such portions of it as empowered the Board to take the initiative in legislation. The Bill would then only enable the Board to oppose measures which they might deem to be adverse to the interests of the metropolis. In these circumstances, Her Majesty's Government would not further oppose the second reading. The Bill was opposed by several members of the House, and after a lengthy debate was rejected by a majority of 54, the numbers being: for the second reading 76, against 130.

Lunatic Asylum Officers in Ireland.

On the 9th inst., in answer to Mr. Corbett, Mr. Morley stated that he believed as a matter of fact lunatic asylum officers are treated in respect of pension pretty much on the same footing as Her Majesty's judges, and far better than permanent Under-Secretaries of State. In Ireland these officers and servants are pensioned on the lines of the Civil Service Superannuation Act. In Scotland he understood they have no pension at all. He did not think it would be possible to induce Parliament to sanction again such terms as have been given in England. Looking to the analogy of the public service generally, it would be difficult to make a case that would satisfy the Treasury of the sufficiency of the claim that all appointments in lunatic asylums in Ireland should be treated exceptionally under the provisions of Clause 4 of the Superannuation Act. The Treasury contribution to public lunatic asylums both in England and Ireland is at the rate of 4*s*. per head per week.

Obituary.

JOHN COOPER FORSTER, M.B. LOND., F.R.C.S.

IT was with a feeling of melancholy surprise, mingled with sincere regret, that the profession received the unexpected announcement that Mr. Cooper Forster had passed away early on the morning of the 2nd inst. A man of magnificent physique, tall, well-grown, and handsome, with a vigour that many a junior might envy, he seemed marked out by nature for a successful career, to be followed by a long term of intellectual age. His professional work terminated only in July last, when he retired at the age of sixty-one from the highest position in his profession, that of President of the Royal College of Surgeons of England. From this time, being possessed of ample means, he determined to leave the field of surgery to his juniors and to spend the remainder of his days in the quiet enjoyment of his family circle. In January he left England with his wife and daughter for a tour on the Riviera. While at Nice he began to lose appetite, which he was inclined to attribute to the difference in diet, but as a feeling of weakness increased he determined to return to England. He travelled home without rest on the way, and arrived at Upper Grosvenor-street in a collapsed state on Wednesday evening, Feb. 24th. He was attended by his colleagues, Dr Habershon and Dr. Wilks, on whose advice his wife and family were communicated with by telegraph. They reached home on Saturday, and he died early on the following Tuesday

Mr. Cooper Forster was born in Lambeth, on Nov. 13th, 1823, and was the son of Mr. John Forster, who practised for many years in that neighbourhood. He was educated at King's College, and afterwards at Guy's Hospital, where he passed through a distinguished career as a student, being one of the first among consulting surgeons to avail himself of the University of London degree, in addition to the Fellowship of the Royal College of Surgeons. He graduated as Bachelor of Medicine in 1847, and was placed second in honours (with a gold medal) in Surgery, and also second in honours in Midwifery. In the following year he was placed eighth for a commission in the army, of which he did not take advantage. In 1856 he was appointed third assistant-surgeon to Guy's Hospital, two having sufficed for the duties up to that time. The following year he distinguished himself by performing the first gastrostomy in England upon a patient suffering from cancer of the œsophagus, under his colleague, Dr. Habershon. He continued to act as assistant surgeon until the retirement of Mr. Hilton in 1870, when he became surgeon to the hospital. In this position he found ample scope for his generous nature and surgical skill. His wards were always beautifully decorated with palms and ferns at his own expense, and his patients received almost paternal care and attention, whilst the sisters and nurses were devoted to his service. It was this which made him feel so acutely the proposals of Miss Burt when first appointed matron; one of which was that the nurses should be removed from ward to ward every

Digitized by Google

three months, and thus be detached from their sister and surgeon. Happily, owing to the protests of the staff, this rule was never carried out. Eventually all the new proposals were subjected to a joint committee of the governors and staff, and the retirement of Miss Burt and the appointment of an amiable successor brought this unfortunate dispute to a close. It is needless to revive the particulars of this bitter controversy, which a little tact and judgment on the part of the executive could so easily have prevented; but the circumstances immediately preceding Mr. Cooper Forster's retirement have never been published. It happened during the long vacation of 1881, when many of the staff were away on their holidays, that an important communication was received from the governors. To this an unfortunately worded reply was sent, and as so many of the staff were absent it was signed only by the senior physician and senior surgeon. The governors regarded this reply as a personal insult, imputing to them bad faith, and retorted by calling upon Dr. Habershon and Mr. Cooper Forster to resign. The staff, on reassembling in October, unanimously resolved to withdraw this note, at the same time (what is not generally known) they almost without exception placed their resignations in the hands of Dr. Habershon and Mr. Forster, to be used in case the governors failed to reinstate them, so that at this time the medical school of Guy's Hospital was on the very verge of being broken up. The governors, however, allowed the note to be withdrawn and reinstated their medical officers, who continued to attend the hospital and to lecture for six weeks longer. At the expiration of their clinical lectures, Dr. Habershon and Mr. Cooper Forster, finding their position intolerable, much to the regret of their colleagues, and without consultation with them, resolved to send in their resignations. In this way Mr. Forster's long connexion with his *alma mater* was abruptly severed. It was not, however, passed over without recognition by his former pupils and the profession generally, who subscribed a handsome testimonial for him and his colleague.

Mr. Forster was a man of strong opinions, vigorous in words and actions. He made firm friends, and, as must happen with men of character, an occasional enemy; but those with whom he differed recognised in him an honest, straightforward opponent. His friendship was of a kind which often extended to his friend's friends, and perhaps sometimes led him into opposition to his friend's enemies. If ever he showed weakness, the influence of someone whose friendship he desired to retain would always be found as the source of his hesitation; but indecision was never one of his characteristics. In his home he was the most hospitable and genial of hosts, affable, kindly, and generous. Fond of society, and possessing many tastes outside his profession, he was an amusing and entertaining companion; an affectionate husband and father, endeared to all alike; and his family was typical of the best features of an English home. In his student days he was much given to boating, and was a distinguished amateur oarsman, an exercise he continued to enjoy almost to the end. Of late years he often spent his leisure hours in fishing, another pastime to which he was warmly attached. He took great interest also in fern-culture, and possessed a very valuable and remarkable collection of filmy ferns, in the cultivation of which he was an acknowledged authority.

As a surgeon Mr. Forster was prompt and decided, and ever ready to test new methods, any good in which he would adopt with enthusiasm. In 1867, after a visit to Scotland, he returned fully impressed with the superiority of acupressure over the old silk suture for the arrest of arterial bleeding, and his opinions were published in the Guy's Hospital Reports for that year. In the next volume he has a paper on Torsion, and soon he had adopted this method to the exclusion of every other. When antiseptic surgery was in its infancy he was the first surgeon at Guy's Hospital to put it to the test, and though he did not afterwards follow the method in all its details, he fully recognised the greater safety which the Listerian system gave to operative surgery. Some years ago, when the temperance movement began to make way and some surgeons proclaimed that patients would recover more rapidly from operations if deprived of stimulants, he determined that at Guy's Hospital treatment without stimulants should have a fair trial, and for a time every patient operated on by him was allowed nothing stronger than milk. This he insisted on with his usual determination and exactitude, and it once led to a curious episode between him and a house-surgeon. One evening a patient was admitted with both legs crushed to the knees, and, as has always been the etiquette at Guy's Hospital, the surgeon, after having amputated one limb, allowed the house-surgeon to remove the other. After Mr. Forster had left, the patient was found to be pulseless, and the house-surgeon, sitting by his side, administered brandy at the rate of an ounce every hour until reaction took place. On the following day, when Mr. Forster arrived and discovered that a large quantity of stimulant had been given, his brow darkened, as he sternly inquired why the house-surgeon had acted contrary to his instructions, and it seemed likely that the junior would pass *un mauvais quart d'heure;* but when he had explained the circumstances, and pleaded that he only desired to give stimulants to the limb for which he himself was responsible, Mr. Forster frankly forgave him, and at once admitted that as one of the principals in the case, and on the spot, the house-surgeon had a perfect right to act on his own responsibility. This was very characteristic of him in his relation to juniors. A man who could defend his opinions was always regarded by Mr. Forster with respect, but one who was cringing and uncertain found with him but little favour. Nervous men, perhaps, did not always receive from him due consideration, as he was one of a school that regarded such as unsuited for the medical profession; but no student ever sought his advice or aid without finding in him an earnest and sincere friend.

Besides contributing numerous papers to the Guy's Hospital Reports and to the Societies, Mr. Forster was the author of a work on "Surgical Diseases of Children," founded largely on his experience at the Waterloo-road Hospital for Children and Women, to which he was attached for a long period. He lectured for many years on Anatomy in the medical school, and his lectures were always popular. Afterwards, on the death of Mr. Poland, he was appointed Lecturer on Surgery; but from this chair he retired on the resignation of Mr. Birkett.

Mr. Forster married, in 1850, Adela, the only daughter of Munden Hammond, Esq., of Kennington, by whom he had seven children, four of whom survive. His wife was an accomplished pianist, and many will remember the pleasant musical evenings at which Mr. and Mrs. Forster delighted to entertain their friends. His married life was of the happiest, but was once crossed by a terrible grief. In 1864 he lost two sons from diphtheria, and it was typical of his paternal solicitude and personal self-control that, when suffocation was imminent, he performed the operation of tracheotomy with his own hands.

Mr. Cooper Forster's commanding presence and handsome face will long be missed in the profession of which he was so distinguished an ornament, and a large circle of friends will mourn over the loss of a man of the highest integrity and moral worth.

JOHN CAWOOD WORDSWORTH, F.R.C.S.

IN the subject of our notice there has been lost to the profession a man who, in his quiet unassuming way, had done much for the advancement of its knowledge, and, firm in his honesty of purpose and freedom from the arts of those who "creep and climb into the fold," was to all who knew him intimately an admirable example of the genuine "dignity and reputation of the profession." With all the modesty of true merit, Mr. Wordsworth was unobtrusive almost to a fault; and overshadowed as his life had been for many years by a sense of physical weakness, and, of late especially, by a growing conviction that he also was to be removed prematurely by the like heart failure which had proved fatal to his two brothers, it happened, doubtless, that he was to some extent disqualified, both by his *morale* and by his *physique*, for attracting all the notice he deserved. Among those, however, with whom he was closely associated, his colleagues, contemporaries, and pupils in early days at the London Hospital, his colleagues in the East (when doing good service in Smyrna and in the Crimea), his colleagues and pupils at the Ophthalmic Hospital—among all these were well known the ability, accurate observation, sound judgment, practical skill, and, not least admirable of all in these our days, the honesty, the candour, and the loyalty to his professional brethren, which were his attributes. With his patients, and in private life, he was especially attractive by reason of his gentleness (how often mistaken nowadays for feebleness), his thoughtful con-

Digitized by Google

sideration for others, his sympathetic nature, his geniality, and withal his keen but quiet sense of humour qualities which always invited, and never disappointed, the fullest and most implicit confidence.

John Cawood Wordsworth was born in 1823, at Manchester, where his father, the Rev. William Wordsworth (sprung from a collateral branch of the poet's family in Yorkshire), was then a curate. In 1840 he was apprenticed to a well-known general practitioner of Manchester, Mr. John Jesse; and to the end of his days he never ceased to acknowledge the benefits he derived from his association with that gentleman, and to advocate the advantage to anyone intended for the medical profession of a well-ordered apprenticeship, with its early initiation in the routine and the (so-called) "little expedients" of general practice. Proceeding in due course to enter at the London Hospital, he became an earnest and diligent student, and presently, and for two years, acted as house-surgeon. So unremitting was he in his devotion to his duties that, not long after completing his qualifications, his health began to suffer, and his constitution (to quote a good expression of his father), not being "town-tempered," threatened to break down. Acting upon the advice of Dr. Pereira and some other of the authorities of the time, he determined to go to Madeira; but accident took him to the West Indies, where he settled himself down in St. Kitt's in practice. At the end of two or three years, however, his health being apparently thoroughly restored, he returned to London, and in 1849 was elected demonstrator of anatomy and assistant-surgeon to his old hospital, and became a little later one of the assistant-surgeons to the Royal London Ophthalmic Hospital in Moorfields.

In 1855, obtaining leave of absence from the governors of his hospital, Mr. Wordsworth answered to Mr. Sydney Herbert's call for volunteers in aid of the over-taxed military medical staff in the East, and went as surgeon to the Civil Hospital in Smyrna. Situated too far from the scene of active operations, the Smyrna Hospital offered but little opportunity for surgical practice, and he, together with some of his colleagues, proceeded to the Crimea, where he arrived just in time to render good service "in the front" to those wounded in the attack upon the Redan. For three months during the following winter he was attached to the Castle Hospital on the heights above Balaclava, and there his sound surgical knowledge, ready resource, and untiring devotion to duty found ample opening for exercise and ready and grateful recognition. The Crimean medal with Sebastopol clasp, and the Turkish medal, were awarded to him for these services at the termination of the campaign. Returning to Smyrna in the spring of 1856 he married a daughter of M. Chasseaud of that place, and came back to his old house in Finsbury-square. In 1859, wishing to devote himself especially to ophthalmic surgery at the West-end, he resigned his appointment at the London Hospital, "in compliance with the" (then existing) "regulations of that charity," and removed first to Queen Anne-street, and a few years later to Harley-street. As full surgeon to the Ophthalmic Hospital, he continued to utilise the vast (wellnigh overwhelming) material afforded by that institution, until, "compulsorily retired" by inexorable Time, he became consulting surgeon in 1883, having endeared himself during his thirty-one years' service to all who came in contact with him by his many lovable qualities. He was a vice-president of the Medical Society and of the Ophthalmological Society.

The expression employed above, "his health being apparently thoroughly restored" during his stay in the West Indies, was used advisedly. The improvement probably was more apparent than real. Some permanent defect in his blood-making power had, not unlikely, resulted from the lung mischief which at that time threatened his destruction, and was slowly, but surely, impairing his nutrition. It was not less than fifteen years ago that marked symptoms of a feeble heart first showed themselves, and these being aggravated (perhaps caused) by the effect of repeated attacks, more or less insidious and occasionally severe, of rheumatic gout, soon left but little room for doubt that he was to be the victim of cardiac muscular degeneration. And it was in this way that the end came, with frequently recurring paroxysms of angina pectoris, all borne "without one fretful word," and at the last, happily, with a painless pericardial effusion.

Mr. Wordsworth died on Feb. 22nd leaving a widow and one son, who is also a surgeon.

JOHN ARCHER, F.R.C.S.

ON Monday evening, the 8th inst., Mr. John Archer died, after a slight attack of angina pectoris, of which he had several severe seizures during the preceding week. He was seventy-seven, and had practised in Birmingham, his native town, upwards of fifty years. He was a good type of the general practitioner of the old school—honourable, hard-working, and successful. He was for some years one of the surgeons to the Birmingham Lying-in Hospital, and a director of the local Medical Benevolent Society. He was also a past president of the Birmingham Medical Institute, of which he had been uniformly a liberal supporter. A staunch Conservative and churchman, hospitable, and a good man of business, Mr. Archer held a much respected position.

Medical News.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on the 4th inst.:—

Andrews, Charles, M.R.C.S., Hammersmith-road.
Shaw, Arthur Orokat, Thorfolk-road.
Snow, Lionel Mason, King Henry's-road.
Soy, Edward, South Lambeth-road.
Vernon, Arthur Heygate, Macaulay-road, Clapham.

On the same day the following gentleman passed the Primary Examination:—

Priestley, Percy, Sheffield School of Medicine.

THE death is announced of Dr. E. Zillner, privat docent in forensic medicine in Vienna.

ON the 3rd inst. the wife of a horse breaker at Beverley gave birth to four girls, all of whom are living and doing well.

HERBERT PENNEL HAWKINS, B.A., of Pembroke College, has been elected to a Radcliffe Travelling Fellowship at the University of Oxford.

A DEPUTATION recently attended at the Local Government Board Offices to protest against the erection of a small-pox hospital at Darenth by the Metropolitan Asylums Board.

VACCINATION GRANT.—Mr. T. Palmer Stephens, of Emsworth, Hants, has received the Government grant for efficient vaccination in the Westbourne Union and the Havant Union respectively (sixth time).

AWARD FOR EXTRA MEDICAL SERVICES. — The guardians of the Havant Union have voted Mr. T. Palmer Stephens a cheque for £20 and their thanks for his extra services and attention to the poor during the epidemic of enteric fever at Emsworth, during the autumn of 1885.

AT a meeting of the City Commissioners of Sewers on the 9th inst., a committee was appointed for the purpose of considering the advisability of sinking wells for supplying the citizens of London with water. The experiment has, it was stated, been successfully carried out by more than one large City firm.

UNIVERSITY OF CAMBRIDGE.—The examinations for medical and surgical degrees will be held on the following days of the Easter term:—First examination for M.B. degree, June 5th; second examination, June 8th; third examination, part 1, May 11th, part 2, May 12th; Bachelor of Surgery, May 15th; Master of Surgery, May 14th.

WHILST Mr. Stowell, M.R.C.S., of Brighton, was driving down Marine-parade, Brighton, a day or two ago, his horse bolted and dashed through a large plate glass window of a shop in Castle-square. Mr. Stowell was so much injured that he had to be taken to the Sussex County Hospital, where he is expected to remain some days.

MEDICAL MAGISTRATES.—The Lord Chancellor has, on the recommendation of the Earl of Ducie, Lord Lieutenant, appointed Dr. Paine, F.R.C.P. Lond., of Stroud, to the Commission of the Peace for the county of Gloucester.—Dr. Frederick H. Daly of Amhurst-road, Hackney Downs, has been appointed a Justice of the Peace for the county of Middlesex, by the Lord Chancellor, on the recommendation of Lord Enfield, Lord-Lieutenant of the county.

PRESENTATION.—A beautifully illuminated address, framed in oak, with a pair of brass candlesticks and an inkstand, have been presented to Mr. Stenson Hooker, L.R.C.P. & L.R.C.S., on his leaving Midhurst, by the members of the Midhurst Literary Institute, of which he was the hon. secretary.

GLASGOW OPHTHALMIC INSTITUTION. — The seventeenth annual general meeting of the donors and subscribers to this institution was held on the 8th inst. The number of patients treated during the year was 3295, of whom 380 were received into the hospital. The income amounted to £1129, falling short of the expenditure by £120.

ASYLUM FOR CHILDREN WITH CHRONIC DISEASES.—Prince N. Usupoff has given 5000 roubles (£500) towards building an asylum for poor children in St. Petersburg who have been discharged from the hospital for children with chronic diseases. The example of the Russian prince might well be followed by many wealthy persons in this country.

ROYAL LONDON OPHTHALMIC HOSPITAL.—The annual general meeting of the governors of this hospital was held on the 9th inst. During the past year 2118 patients have been admitted to the wards, or 90 more than in 1884, and the number of out-patients was 25,863. The annual subscriptions amounted to £757, and the donations, including legacies, to £4473. The excess of expenditure over income was £303.

SMALL-POX HOSPITAL FOR BRADFORD.—At a meeting of the Bradford Town Council on the 9th inst., it was resolved to contribute the sum of £2000 towards the cost of providing a small-pox hospital in the event of the same being built by the commttee of management of the Bradford Fever Hospital on their land, according to plans to be approved by the corporation, and on condition that such small-pox hospital shall be used exclusively for the accommodation of persons residing in the borough.

ABERDEEN HOSPITAL FOR SICK CHILDREN.—The annual meeting of subscribers to this institution was held on the 3rd inst., when it was reported that the new buildings, affording accommodation for about sixty children as in-patients in the general wards, and eighteen in the infectious wards, were completed. The total number of patients who received benefit during the past twelve months was 1054. The total cost of the extension is estimated at £7154, to make up which a sum of £2275 is still needed. The income amounted to £711, and the expenditure to £717.

BRITISH LYING-IN HOSPITAL.—On the 5th inst., at the annual meeting of the governors of this charity, it was reported that out at a total of 822 cases treated during the past year, there had only been one death. The governors have sanctioned a system of admitting a few paying patients in order to utilise a portion of the hospital premises, but this will in no way encroach upon the funds of the institution or interfere with its benevolent work. The number of annual subscribers has lately suffered a diminution, and the committee appeal for further public support.

WESTMINSTER OHPTHALMIC HOSPITAL.—The annual meeting in connexion with this charity was held on the 5th inst., when a highly satisfactory report was presented by the committee. Since its foundation in 1816 to the 1st of January, 1886, 347,878 persons have availed themselves of the benefits conferred by the hospital. Of this number 12,097 have been admitted as in-patients, and operations have been performed in 25,308 cases. There is accommodation for fifty in-patients, but only fourteen free beds can now be occupied, owing to want of funds.

THE SANITATION OF CALCUTTA.—A most important memorial to the Lieutenant-Governor of Bengal on this subject is now in circulation. It has been signed by all classes of the population and by the entire body of local physicians, and states that since the year 1881 cholera has swept away more than 20,000 people in Calcutta and its suburbs, that in some suburban wards the death-rate has stood at 70 in the 1000, and that during the decade of 1875 to 1884 out of a population of 257,000 in the suburbs no fewer than half have perished. The memorial points out that this mortality is clearly traceable to defective sanitation. It expresses hearty concurrence with the Government policy of strenuous sanitary reform, and suggests certain legislative and other changes which the emergency renders necessary.

BY invitation of the Council a large party assembled on the 25th ult. to inspect the new wards which have recently been erected in connexion with the Royal Hospital for Diseases of the Chest, City-road, at a cost of about £12,000.

NORTH LONDON HOSPITAL FOR CONSUMPTION.—The annual report which was read at the meeting of the governors of this institution on the 10th inst., stated that, notwithstanding the commercial depression, there had been a steady improvement in the revenue of the hospital, and the number of annual subscribers had increased. The total receipts for 1885 had been £4837 11*s.* 2*d.*, against £3029 2*s.* 6*d.* for the previous year. The total liabilities had been reduced from £3610 19*s.* to £2406 4*s.* 3*d.*; but there was still a mortgage of £5000 on the hospital at Hampstead.

DEATHS AT VERY ADVANCED AGES.—Two deaths at very advanced ages are reported in the Russian journals. One is that of a Jew named Sribny, aged 117, in Pereyaslaff, in the province of Poltava, who seems to have retained all his faculties to the last, his eldest son, who is 82 years of age, being less active than his father was just before his death. The second case, which is more exceptional still, is that of a woman named Annah Kubova, who lately died in the province of Baku at the age of 130, and who, with the exception of failure of eyesight, retained her health and intellect to the end. Our authorities for these cases are respectively the *Kiefflyanin* and the *Kaspii*.

ROYAL SURREY COUNTY HOSPITAL.—On the 27th ult. it was reported at the annual meeting of the governors of this institution that 572 in-patients, 166 home patients, and 3279 out-patients had been treated during the past year. It is hoped that the new wing, intended for the reception of thirty additional patients, will be completed and ready for occupation by next winter. The total income amounted to £3769. After the report of the committee had been read and adopted, a lengthy discussion took place on the question of home visitation and the house-surgeon's duties. Many of those present joined in the debate, but no resolution was adopted, and the subject was allowed to drop.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BROWN, WILLIAM J., B.A., M.B., L.R.C.S.I., has been appointed Certifying Surgeon of Factories for the Chester-le-Street District.

CLEAVER, Mr. EDWARD L., has been appointed Public Analyst by the Fulham Vestry.

COLLINGRIDGE, WILLIAM, M.A., M.D., M.R.C.S., has been appointed by the Port Sanitary Committee Public Analyst to the Port of London.

EGAN, FRANCIS, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer of Health by the Fulham Vestry.

HANDFIELD-JONES, MONTAGU, M.B., M.R.C.P., has been elected by the Governors Physician to the British Lying-in Hospital.

HOPE, E. W., M.D.Ed., B.Sc., L.R.C.P.Lond., Assistant Medical Officer of Health for the City and Port, has been appointed to the Lectureship on Public Health at University College, Liverpool.

HYDE, JOHN K., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Earl's Barton District of the Wellingborough Union.

LEFTWICH, C. HARCOURT, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the West Deptford District of the Greenwich Union.

MALET, HENRY, M.D., M.A.Dub.Univ., has been appointed Honorary Physician to the Wolverhampton and Staffordshire General Hospital.

MOLONY, M. J., L.R.C.P., L.R.C.S., has been appointed Surgeon to the Parnell Quarries, Arklow.

POWELL, H. A., M.A.Oxon., M.R.C.S., &c., has been appointed Honorary Medical Officer to the All Saints' Home for Women and Children, Beckenham.

RIGG, JOHN, M.B., C.M.Ed., has been appointed Medical Officer for the Seventh District of the Preston Union.

ROBERTS, H. W., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the South Deptford District of the Greenwich Union.

SHAW, HARRY CHARLES COSTELLO, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer of Health for the Mildenhall Rural District; and Public Vaccinator for the Lakenheath District of the Mildenhall Union, Suffolk, vice W. T. Angove, M.R.C.S., L.S.A.Lond., resigned.

SHORLAND, WALTER E., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Third District of the Barton Regis Union.

WALKER, J. B., M.R.C.S., late Resident Obstetric Assistant to University College Hospital, has been appointed House-Surgeon to that Institution.

WILLIAMS, MUZIO, R., M.R.C.S., L.R.C.P., L.S.A.Lond., has been appointed Assistant Resident Medical Officer to the London Fever Hospital, vice O. Fowler, M.D., resigned.

Births, Marriages, and Deaths.

BIRTHS.

BLAKE.—On the 1st inst., at Blackfriars-road, London, the wife of Walter B. Blake, L.K.Q.C.P.I., L.R.C.S.I., of a daughter.

COATS.—On the 6th inst., at The Mount, Fleetwood, Lancashire, the wife of Surgeon-Major J. Coats, Army Medical Staff, of a daughter.

GARDNER.—On the 9th ult., at Bareilly, N.W.P., India, the wife of E. B. Gardner, M.R.C.S., L.R.C.P.Ed., Civil Surgeon, of a daughter.

HAYLE.—On the 7th inst., the wife of T. H. Hayle, M.B., of Rochdale, of a daughter.

NEALE.—On the 28th ult., at London-road, Leicester, the wife of J. Headley Neale, M.B., &c., of a daughter.

PLAYFAIR.—On the 1st inst., at Rutland-street, Edinburgh, the wife of John Playfair, M.B., F.R.C.P.E., of a daughter.

ROBERTS.—On the 2nd inst., at Dragonfield, Uxbridge, the wife of Charles Roberts, M.R.C.S., of a daughter.

ROBERTSON.—On the 4th inst., at Gonville House, Roehampton-park, S.W., the wife of A. Milne Robertson, M.D., of a daughter.

WARD.—On the 6th inst., at Casita, Northumberland-park, Tottenham, the wife of A. Ogier Ward, M.B., of a son.

MARRIAGES.

BLAMPIED—DE GARIS.—On the 3rd inst., at the Town Church, Jersey, John William Blampied, M.R.C.S., L.S.A.Lond., L.M., of West Grove, St. Lawrence, to Alice Mélanie, eldest daughter of Colonel De Garis, Commanding late 4th Royal Guernsey, of St. Saviour's, Guernsey.

EAST—GARMAN.—At St. Stephen's, North Bow, E., by the Rev. T. R. Lawrence, Vicar, Arthur James East, second son of Joseph East, Esq., of The Limes, East Ham, Essex, to Martha, second daughter of Dr. H. V. Garman, of Kent House, Bow-road.

GOULD—WOODRUFF.—On the 3rd inst., at the Parish Church, Leamington, Ernest Edward Gould, M.R.C.S., of Hailsham, Sussex, youngest son of John B. Gould, of Exeter, to Charlotte, eldest daughter of the late John Farrer Woodruff, of Leamington.

MACLEHOSE—MACMILLAN.—On the 6th inst., at Holy Trinity Church, Upper Tooting, Norman Macmillan MacLehose, M.B., of Sevenoaks, youngest son of the late James MacLehose, of Glasgow, to Olive, second daughter of Alexander Macmillan, of Knapdale, Upper Tooting.

PIGEON—GRINDLEY.—On the 9th inst., at St. Anne's, Highgate-rise, N., by the Rev. C. T. Ackland, M.A., assisted by the Rev. C. C. Buss, M.A., Henry Walter Pigeon, M.A., M.B., B.C., F.R.C.S., of Albion-street, Hull, son of Colonel Pigeon, of Bristol, to Nellizzie, second daughter of the late R. Dutton Grindley, Esq., of Highgate, N.

RANKIN—BEEDLE.—On the 23rd ult., L. K. Rankin, M.A., F.R.C.S., to E. Beedle.

SOUTAR—CLARK.—On the 3rd inst., at Barnwood, near Gloucester, James Greig Soutar, M.B., of Barnwood House, to Mary, daughter of the late Rev. J. P. Clark, M.A., Minor Canon and Precentor of Gloucester Cathedral.

THOMSON—WILLIS.—On the 3rd inst., at All Saints', Blackheath, George Lawson Thomson, M.D., of Wootton-hill Lodge, Newbury, to Emily, youngest daughter of the late Thomas Willis, M.D., M.A.Cantab.

WOOLFRYES—MACEWEN.—On the 9th inst., at St. Stephen's, Bayswater, Surgeon-General J. A. Woolfryes, M.D., C.B., C.M.G., to Ada Sophia, youngest daughter of Alexander Palmer MacEwen, of Woodend, Southsea, Hants.

DEATHS.

ARCHER.—On the 8th inst. (after a few days' illness), John Archer, F.R.C.S., of Carpenter-road, Edgbaston, aged 77.

BATTEN.—On the 27th ult., at Ty Gwyn, Brewood, Staffordshire, John Batten, L.R.C.P.Ed., L.F.P.S.Glas., eldest son of A. Batten, Esq., late of Aberdeen, aged 37.

BISHOP.—On the 6th inst., at the Hôtel des Anglais, Cannes, John Bishop, M.D., F.R.C.S.E., Assistant Surgeon to the Royal Infirmary, Edinburgh, aged 44.

BROWN.—On the 5th inst., at Milton Grange, Stourport, George Gwynn Brown, M.R.C.S., in his 76th year.

DOUGLAS.—On the 7th inst., at Woodside, Kelso (after a short illness), Surgeon-Major Francis Douglas, M.D., late of H.M. Bengal Army, in his 71st year.

GUTHRIE.—On the 3rd inst., at Fort Pitt House, Rochester, Alexander Guthrie, Deputy Surgeon-General, Medical Staff, aged 53.

O'CONNOR.—On the 3rd inst., at his residence, King's-terrace, Southsea, Jacob Robertson Headlam O'Connor, M.D., aged 44.

OXLEY.—On the 6th inst., at Wellington Villa, Portswood Lawn, Southampton, Thomas Oxley, M.D., M.R.C.P., formerly Chief of the Bengal Medical Staff, aged 80.

READ.—On the 8th inst., at The Close, Salisbury, Raphael Woolman Read, F.R.C.S.Eng., Deputy Inspector-General of Hospitals, aged 67.

STORRAR.—On the 10th inst., at the residence of his brother, Stratheden House, Blackheath, John Storrar, M.D., late Chairman of Convocation of the University of London, in his 75th year.

WATSON.—On the 4th inst., at Burnopefield House, co. Durham, Henry William Watson, F.R.C.S., aged 66.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, March 15.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Frederick Treves: On the Anatomy of the Intestinal Canal and Peritoneum in the Mammalia.
SOCIETY OF ARTS.—8 P.M. Mr. Boverton Redwood; Petroleum and its Products (Cantor Lecture).
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. The following cases will be shown. Mr. Edmund Owen: Boy with Reproduction of Upper End of Femur after Furneaux Jordan's Amputation.—Mr. Startin: (1) Case of General Xanthelioma; (2) Diffuse Scleroderma; (3) Angioma. Dr. C. T. Williams: A case of Mediastinal Tumour. Other cases and specimens.

Tuesday, March 16.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee: The Function of Circulation.
PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Drs. Goodhart and Hale White: Trabeculated Skull in an Infant.—Dr. Percy Kidd: Diffused Symmetrical Cirrhosis of Lungs.—Dr. Hadden: (1) Tumour of Stomach; (2) Single Cyst of Liver (card).—Sir W. Mac Cormac: Tumour of Palate.—Mr. R. Williams: Acute Nephritis in Lambs.—Dr. Handford (Nottingham): (1) Unusual case of Ante-mortem Digestion of Stomach; (2) Right-sided Ulcerative Endocarditis (card); (3) Acute Intestinal Obstruction due to a Band (card); (4) Thrombosis of Left Posterior Cerebral Artery (card); (5) (for Mr. E. Powell) Congenital (?) Atrophy of Right Kidney (card).—Mr. F. T. Paul (Liverpool): (1) Congenital Adeno-sarcoma of Kidney; (2) Calcification of Arteries.—Dr. G. N. Pitt: Hydatid of Liver Embedded in a Syphilitic Deposit.—Dr. Sainsbury: Pyonephrosis from Valvular Obstruction of Ureter.—Dr. Pasteur: Aortic Aneurysm with Mitral Stenosis (card); Mr. Fenwick: Post-trigonal Pouch containing Stone (card).—Mr. Shattock: Lumbo-sacral Meningo-myocele cured by Morton's treatment (card).—Mr. Ballance: Fracture of Thyroid Cartilage (card).

Wednesday, March 17.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Frederick Treves: On the Anatomy of the Intestinal Canal and Peritoneum in the Mammalia.
SOCIETY OF ARTS.—8 P.M. Mr. Vincent Robinson: Eastern Carpets.

Thursday, March 18.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. W. Boyd Dawkins: The Ancient Geography of Britain.
ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Mr. S. J. Sharkey: On Spasm in Chronic Nerve Disease (Gulstonian Lecture).
PARKES MUSEUM OF HYGIENE.—8 P.M. Captain M. P. Wolff: The Rational Alimentation of the Labouring Classes.
HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Mr. G. R. Turner: A case of Compound Fracture of the Patella.—Mr. Edmund Owen: Sprained Joints.

Friday, March 19.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

HYDROPHOBIA, ITS PREVENTION AND TREATMENT.

Dr. Illingworth (Clayton-le-Moors) writes to suggest that the biniodide of mercury should be used in the treatment of hydrophobia, and also as a prophylactic in cases of dog-bite, in view of its well-known and powerful action in destroying the germs of syphilitic poison in the blood. Of course, local measures should not be neglected.

Twenty Years' Subscriber.—Certainly not. The prescription is the property of the patient.

Inquirer (Leeds) should consult his ordinary medical attendant.

"SCARLET HOSIERY."

To the Editor of THE LANCET.

SIR,—Permit me to ask through the means of your valuable journal in what way Mr. Woodland's friend suffered from wearing scarlet socks and stockings. Did he suffer from that troublesome and obstinate form of eczema known as arsenical eczema, or from induction by local contact, occurring on the dorsum of the foot, and more particularly on the anterior and lateral aspects of the leg?—or did he suffer from some of the forms of skin disease produced when arsenic is absorbed into the system, with the production of a variety of furunculi or yellow pigmentation of the body or other concomitant symptoms and signs connected with the lower part of the alimentary tract, which are some of the expressions of chronic arsenical poisoning? So far as my experience extends, wearing scarlet hosiery next the skin produces an obstinate form of eczema to treat and not the other conditions mentioned herein, unless the poison has been imbibed per orem for a lengthened period. But it would be interesting to know if any of the above-mentioned conditions or something new has supervened, provided there be exclusion of the use of arsenic as a remedial agent. I have seen, from wearing merino pants of a reddish tint, eczema of the thighs in patients who are addicted to sweat more than the ordinary. The eczema here, as in that from socks, &c., was of an obstinate nature to cure. I have also qualitatively tested bits from pants which produced eczema and found them to contain arsenic.

I am, Sir, yours truly,

March 2nd, 1886. W. A. HOLMES, M.B., &c.

"SYMPATHETIC IRRITATION OF THE PNEUMOGASTRIC."

To the Editor of THE LANCET.

SIR,—Allow me, in answer to Dr. Towers-Smith's request for information upon this subject, to state that I have found great benefit to be derived in these cases from the administration of valerianate of soda in three-grain doses. Valerian, besides being a direct tonic stimulant to the nervous system, undoubtedly has a powerful anæsthetic effect upon the nerve terminals of the vagus in the stomach.

I am, Sir, yours faithfully,

GEORGE HERSCHELL, M.D. Lond.

Moorgate-street, E.C., March 2nd, 1886.

MEDICAL EVIDENCE IN COURTS OF LAW.

Walter Weir, M.B.—We have many times replied to the question our correspondent submits to us. A medical witness is not bound to give evidence as to his opinions; but the difficulty—and it is almost an insuperable one—of determining what constitutes opinion and what mere fact always arises. What is commonly regarded as a "simple fact"—a circumstance grasped and understood at once by the ordinary observer—is in reality an inference, and to draw an inference practically means expressing an opinion. Moreover, if a witness has been examined in a public court, and has stated the result of his observations and the conclusions he drew from them, he can be made to repeat the substance of his depositions when the case is brought before a jury or is otherwise tried; for he has merely to be asked if he spoke the truth on the occasion when he was before the magistrate to give all that is required of him. In civil cases there is no fear of his being deprived of the just reward of his services; for if his clients refuse to pay the fee beforehand, he has only to say that his evidence may or may not be to their advantage. This is a sufficient inducement to secure payment of the "shekels." After all, there are but few instances in which solicitors are mean enough to commit a breach of faith. If our correspondent cannot afford to attend a court for the remuneration specified, he should avoid being a witness of fact, and then he cannot be a witness of opinion.

H. Campbell is referred to the last balance-sheet of the company, to a copy of which every policy-holder is entitled.

Sig. L. Corazza (Verona).—We have unfortunately no recollection of the article mentioned.

SPECIALISTS.

To the Editor of THE LANCET.

SIR,—Your opinion, or that of the profession, upon the following matter will greatly oblige.

I have acted as medical adviser to a family for about two years. Lately I have been treating one of their children. Some time ago, without my knowledge, the parents took this child to Dr. A. He said that he did not treat children, and advised them to go to Dr. B. They went, and when there—the mother of the child tells me—asked Dr. B. if he would meet me in consultation. He said it would be better to continue to bring the child to him. I understand the child was taken several times to his office. Some time ago this same child became ill. The parents requested Dr. B. to call. This he did, and continued to call. Some days ago the child had an attack of convulsions. I was sent for, when the mother made the above statement. At this visit she also told me that Dr. B. had spoken to her concerning the valuable experience he had, owing to the fact that he was connected with a children's hospital. He also added that he not only saw the children during life, but also after death, and that sometimes he had detected "little lumps" on their brain (the parents thought the child had some brain disease).

Now, Sir, I wish to know if Dr. B. acted a professional part in refusing to meet me in consultation when requested to do so; also, was it not his duty—even supposing the parents wished his opinion—to refer them back to me, and for me to arrange for a consultation. I may add that I care not a penny piece for any patient, but my experience has taught me that there is a certain class of doctors who dub themselves "specialist" or "consultant." In this way they induce one's patients to their office, dilate to them on the advantages of hospital experience and specialism, and the next event is—they have added that patient and the family to their general practice.

May I, at the same time, ask you if a doctor has any right to call himself a "consultant"? Mr. Justice Hawkins some time ago ruled that a consultation can take place only between two or more members of the medical profession. He made this remark when a doctor in court said of himself, "I am a consultant." I am, Sir, yours obediently,

March, 1886. M.D.

*** As represented above, the consultant's conduct is quite indefensible. We agree that a consultant is one who consults with his professional brethren.—ED. L.

KISSING THE BOOK.

To the Editor of THE LANCET.

SIR,—I took an opportunity which was offered to me last Thursday, in Mr. Justice Butt's divorce court, to raise a protest against the present manner of administering the oath to witnesses. Two notorious prostitutes had kissed the New Testament a short time previously, and I held that there was in consequence a risk of contagion. Apparently my protest amused the learned judge and many of the barristers, while others expressed their approval of the course which I had taken. Mr. Justice Butt met (as he thought) my objection by asking me to kiss the opened book, and the example may be followed by the diseased and healthy alike. But this does not meet the natural objection of a medical man to *handle* an unclean article. In a divorce court prostitutes will ever be called upon to give evidence, and will probably appear at every sitting; and, for aught I know, the cherished heirlooms which are called New Testaments may have been kissed and handled by generations of diseased individuals. I mentioned the fact in court that an article upon the subject had appeared in THE LANCET.

I am, Sir, yours faithfully,

Derby, March 6th, 1886. THOMAS HARKNESS.

EYE DISEASES AMONGST RUSSIAN SOLDIERS.

AMONGST the various communications made to the recent Russian Medical Congress on the subject of the prevalence of eye diseases in Russia was one by Dr. Tikhomaroff on the character of the regimental ophthalmic cases in the St. Petersburg district. These cases numbered in 1884 11·63 per cent. of the strength. The most frequent were conjunctival affections. Trachoma, too, was common. In one district hemeralopia occurred very often, the cause not being as yet clearly understood.

Inquirer.—General antisyphilitic treatment with cod-liver oil, and a lotion composed of tinct. cantharidis (ʒ ii.), with spirits of wine (ʒ ii.), lin. saponis (ʒ vi.), and ol. rosmarini (ɱ v.). If alopecia supervene in the secondary stage, it is generally amenable to treatment, but very difficult to cure later on.

LEAD-POISONING FROM MINCING MACHINES.

To the Editor of THE LANCET.

SIR,—Twenty years or so spent for the most part in examining the teeth and gums of all sorts and conditions of men ought, one would think, to render a man perfectly familiar with any appearance that these parts of the human frame can possibly present under any conceivable conditions of health or disease. Yet, strange to say, the phenomena I am about to describe, though in my experience far from uncommon, seem almost entirely to have escaped notice, or, if they have been recognised, to have been attributed to other causes than the true one. In examining the mouths of persons applying to me for professional advice, I have often been surprised by the presence of the blue line on the gums so well known as characteristic of lead-poisoning, and with it the less definite, but to the eye of an expert scarcely less striking, unhealthy appearance of the tongue and palate. I say I have been surprised, for my patients were not of the class one meets in hospital and dispensary practice, men working in lead and not paying too much attention to their personal habits; on the contrary, it was among those patients who were the most intelligent, careful, and well-to-do, those who best appreciated the importance of a thorough comminution of the food as a consideration of its proper exposure to the action of the saliva—it was among such that I most often met the "blue lead line." It was not industrial poisoning, that was certain, and I was eventually led to conclude that it must be from some habit or practice to which all my patients alike had been led by some motive common to themselves but not to others—i.e., to their families. This one condition, then, could be no other than the absence of teeth and inability to masticate, and the consequent practice of employing some mechanical substitute for mastication in preference to bolting their food, as less careful individuals of the variety *homo edentulus* do. In fact, in every case of a blue line on the gums of persons who had lost the majority of their teeth I found on inquiry that the individual constantly employed a mincing machine, and that his meat was cut up by it for him, whereas the other members of the family used it only on the comparatively rare occasions when all partook of mincemeat or sausage. I next proceeded to examine a number of the machines in question at the houses of friends, in the shops, and at one of the exhibitions at the Agricultural Hall, and found that in all the mill was formed by a number of small wheel-like segments strung on a rectangular axis, and each bearing three rudely-cut, oblique teeth, working between a series of fixed plates or blades. The latter were of steel; but the former, I found to my surprise, were of pure lead, so soft as to be easily cut with a knife or scratched with the thumb-nail, and leaving a black line when drawn along a sheet of paper; should they be pressed against one of the fixed blades, a thin film or shaving of lead would be worked off, and since meat when raw has always a slightly acid reaction from the presence of lactic acid, a certain amount of the lead must be liable to solution in the juice. Fats, too, though not containing any free acid, act in the same way on lead. Many obscure forms of dyspepsia may be traced to chronic lead-poisoning too mild to exhibit the commonly recognised symptoms. At any rate, the use of lead in contact with moist and acidulous articles of food in a machine involving a considerable amount of friction cannot but be a source of danger to health, though it is only in the case of persons who use such machines daily that unmistakable symptoms are produced; and I think that some substitute of a harmless metal or a hard wood ought to be insisted on.

I am, Sir, yours faithfully,

February, 1886. CHODWICK BROWN.

THE CASE OF H. P. FREUND.

To the Editor of THE LANCET.

SIR,—Seeing Dr. Mears' letter in your issue of the 27th ult. (p. 430) concerning Herbert Percy Freund, I should be glad if you would kindly give me space to say a few words upon the subject. I feel sure that there are many good, kind-hearted men at St. Thomas's Hospital who would be willing to subscribe to a fund for so sad a case, if someone would volunteer to open one. I, for one, would be pleased to give my small contribution. I cannot refrain from asking why the London University men (especially as they consider themselves A 1 in every respect) have not taken up the case long ago, and not left it to our northern university to broach the subject. Is it that Durham men have more sympathy? Be that as it may, I am very glad that Dr. Mears has proposed a relief fund.—I am, Sir, yours truly,

A. J. HELM MONTAGUE, M.R.C.S., &c.,
March, 1886. Durham University and St. Thomas's Hospital.

EASY-THREADING SEWING-MACHINE NEEDLES.

MR. R. BARLOW, M.R.C.S., with the object of saving trouble and avoiding injurious straining of the eyesight, has introduced a sewing-machine needle which, by the provision of a diagonal gap cut in the eye, may be easily threaded by any part in the length of the cotton. The value and convenience of the device will no doubt be appreciated by those accustomed to use sewing machines.

THE USE OF COCAINE IN OPERATIONS FOR PILES.

To the Editor of THE LANCET.

SIR,—The value of cocaine as a local anæsthetic has certainly not been over-estimated. I am not aware that it has yet been used by anyone but myself in the operation for piles; but a perfectly painless and, I believe, very safe operation may be performed by its use. Some three or four weeks ago I was requested to operate upon a gentleman (a chemist), who suggested its use in preference to chloroform. The operation was performed in the following manner. The pile being first bathed with warm water, the dry hydrochlorate of cocaine was dusted over it, which immediately became dissolved in the moisture, and in about ten minutes a grain of the hydrochlorate dissolved in eight minims of distilled water was injected into the base of the pile with the hypodermic syringe, the introduction of which was not felt by the patient. In another ten minutes the pile was enclosed in a very powerful clamp (invented, I believe, by Dr. Downes), which, when screwed down tightly, crushed the base so completely that when the pile was cut away the use of the cautery was hardly necessary. The operation was performed in the evening, and the patient would not consent to remain in bed the next day, but went about his business as usual. He declares that he felt no pain whatever at the time of the operation, and no appreciable pain or inconvenience afterwards. Since then I have performed the same operation, and with equally satisfactory results.

I think the first contribution to THE LANCET on the hypodermic use of cocaine was a letter of mine in your issue of Dec. 27th, 1884, on its use in circumcision. Since then I have used it six times for the same operation, and found it in every case most satisfactory. In one curious instance, nearly twelve months ago, I removed a large Hunterian chancre bodily away with the foreskin, and was naturally curious to see how the parts would heal. The operation was, however, in every way as successful as the rest. I also felt some anxiety about the development of the secondary symptoms, which, however, made their appearance quite in the ordinary way, but disappeared again with remarkable rapidity under ordinary treatment; and although the patient neglects medicine and leads a very irregular life, he does not appear to have suffered from any syphilitic symptoms for some months past. In circumcision I now dust the cocaine on the under surface of the foreskin first, and, the hypodermic syringe being introduced through this surface, even the pain usually caused by its introduction is avoided. I have also used cocaine in many other minor operations, such as amputation of fingers (through a joint); but, of course, in such cases it is impossible to prevent the pain caused by the hypodermic syringe.

I am, Sir, yours faithfully,

Southwick-street, W., Feb. 23rd, 1886. OWEN PRITCHARD, M.D.

PLACENTA PRÆVIA WITH TWINS.

To the Editor of THE LANCET.

SIR,—Mr. Chas. J. S. Digges relates in your issue of Feb. 20th, p. 383, a case of placenta prævia with twins, and regards it as unique. I think I have previously referred to a case of mine that happened about twenty years ago, the circumstances of which I still well remember. Having been from home for some hours, and returning about midnight, I learned that my assistant was engaged with three distinct cases, one being placenta prævia, and finding a note requesting me to come at once, I hastened to his assistance. The woman was very blanched, the flooding being very great. I found the case to be one of complete placental presentation. The os being soft and sufficiently dilated, I lost no time in delivering one child, and on further examination I discovered that there was a second, which was also speedily delivered, accompanied by a severe loss. The uterus, however, quickly contracted, and with a good pad and well-adjusted bandage after the placenta had been removed, all further loss seemed to be at an end, and warmth appeared gradually to return to the surface. I then left the patient in charge of my assistant, as I had to go to one of the other cases, but giving strict directions that he should remain with her until my return. He, thinking her apparently out of danger, left in about an hour. On my return, at about 6 A.M., I found that she had sustained a further slight loss just before my arrival, and had succumbed. Both children were alive, but whether they survived long I do not now remember. This being the only case of placenta prævia I had ever directly lost, it made a strong impression on my mind of the necessity when the exhaustion is great of remaining for some time after delivery.

I am, Sir, yours truly,

Feb. 27th, 1886. GEO. MUNDIE, M.D.

COLOUR-BLINDNESS AMONG MEDICAL MEN.

To the Editor of THE LANCET.

SIR,—I should like to ask through your journal whether colour-blindness is likely to be a bar to success in practice in the medical profession. The defect might not be without importance in the diagnosis of such conditions as iritis, the exanthemata, or in medico-legal inquiries where the practitioner happened to be called upon to give evidence as to colour of hair, eyes, &c., or of clothing worn by an individual. Are candidates for the naval and military medical services examined as to perfect vision for colours? This topic is suggested to me through my having recently discovered that a medical student whom I was teaching in elementary chemistry was unable to distinguish solutions of cobalt and nickel. This led me to experiment further, though in a rough-and-ready way, with various coloured solutions, the result satisfying me that he is certainly very blind for red and green. He has passed his "first," including chemistry, at Edinburgh. If there is any practical analytical work included in that examination, he must have been fortunate in not getting coloured solutions, nor needing to use flame-colour tests. I am, Sir, yours faithfully,

CHARLES H. PIESSE, M.R.C.S.,
Strand, W.C., March, 1886. Fellow of the Institute of Chemistry.

H. W. G.—Some account will be found in the "Book of Health," in an article by Dr. Herman Weber. Such experience as we have of individual phthisical patients has led us to think exceedingly well of the high tableland of the Darling Downs in Queensland. We believe that the opportunities for medical practice are not good; the population is very sparse, and the towns where practice is more promising are mostly situated on the coast, where the climate is much less suited to such cases.

An Earnest Enquirer.—We do not prescribe.

"PITYRIASIS CAPITIS."

To the Editor of THE LANCET.

SIR,—In reply to Dr. Caldwell's inquiry, in your issue of the 6th inst., p. 476, I beg to say that I have invariably found an application of equal parts of ung. hyd. rub. and vaseline most successful, attending to the general health, especially looking out for a gouty diathesis, avoiding brushing the head too frequently, and always using a fine comb or very soft hair-brush. I am, Sir, yours faithfully,

Leamington, March 8th, 1886. CHARLES MARRIOTT, M.D.

To the Editor of THE LANCET.

SIR,—I would advise Dr. Caldwell to try the following simple treatment:—Direct his patient to wash the head with soap-and-water to which has been added half a drachm to a drachm of sublimed sulphur. I think the best plan is to work the sulphur into a thin cream with the lather and wash thoroughly. If Dr. Caldwell will adopt this treatment I think he will be well satisfied with the result.

I am, Sir, yours truly,

Stony Stratford, March 9th, 1886. J. ANDERSON, L.S.A.

Enquirer (Surgeon) may use daily some hair wash, such as one compounded of liquor ammoniæ fort, ℥j.; ol. amygdal. dulc., ℥j; spiritus rosmarini, ℥iv.; and aqua mellis, ℥ij. Or a lotion containing an ounce of tincture of cantharides to six ounces of water, and made agreeable by the addition of rosemary spirit. We should, however, advise our correspondent to take the first opportunity of consulting some authority, who no doubt would be very glad to give a brother advice.

Sigma.—The case might very well be accommodated in the infirmary or insane wards of a workhouse. It does not certainly appear to be one for an asylum.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Spender, Bath; Dr. Brookhouse, Nottingham; Mr. Stephen Paget, London; Dr. Saundby, Birmingham; Dr. Maunsell, Woolwich; Dr. Hughes Bennett, London; Mr. F. Treves,; Dr. Illingworth, Clyaton-le-Moors; Mr. Montague, London; Mr. Laffan, Cashel; Dr. Tremaine, New York; Mr. S. J. A Lecture
ON
FLAT-FOOT AND THE CONSTRUCTION OF THE PLANTAR ARCH.

Delivered at Cambridge.

BY PROFESSOR HUMPHRY, F.R.S.

GENTLEMEN,—Frequent as is the occurrence of flat-foot, we seldom have an opportunity of making a dissection of the part. Such an opportunity having recently been obtained here, I will give you a short account of what we found. But before doing so I will make a few remarks upon the mechanism of the foot, and more particularly of the plantar arch.

The astragalus may be regarded as the key-bone of this arch, being the highest bone and transmitting the weight, which it receives upon its trochlear surface from the tibia, to the two pillars of the arch. Of these pillars, the hinder one, composed of the os calcis only, is short, thick, very oblique, slightly curved, with the concavity inwards, and having little elasticity. The anterior pillar, composed of the scaphoid, three cuneiform and three inner metatarsal bones, is longer, less oblique, and more yielding or elastic. Hence in descending from a height, as from a chair or in walking downstairs, we alight upon the balls of the toes. If we alight upon the heel—for instance, if we walk downstairs upon the heels—we find it an uncomfortable and rather jarring procedure. In walking and jumping, it is true, the heel comes first in contact with the ground, but the weight then falls obliquely upon it and is not fully borne by the foot till the toes also are upon the ground. Though obviously the key-bone of the plantar arch, the astragalus differs in several respects from the key-stone of an ordinary arch. It is not, as a key-stone usually is, wedge-shaped, and so placed between the two pillars as to support and receive support from them, and thus to complete and give stability to the arch. The fore part of the astragalus, it is true, may be said in some measure to fulfil these requirements by the apposition of its ball-like anterior surface to the concave hinder surface of the scaphoid bone; but, posteriorly, the astragalus quite overlies and rests upon, without at all supporting, the os calcis. Hence the configuration of the bones has to be supplemented, and the arch is in great measure sustained, by the soft parts. Thus the os calcis, or hinder pillar, is held up to (not supported by) the astragalus by means of the interosseous ligament passing between and binding together the two bones. Secondly, the arch is braced underneath, and the two pillars are held together, by the strong calcaneo-scaphoid ligaments passing from the under and fore part of the heel-bone to the under and hinder part of the scaphoid bone; and these ligaments also directly support the head of the astragalus. Thirdly, the arch is supported on the outer side by a secondary or subsidiary arch continuous with it, which is formed by the outer part of the os calcis, the cuboid bone, and the outer two metatarsal bones; and this subsidiary arch is, in turn, held up by the calcaneo-cuboid ligaments. Fourthly, the plantar fascia extends between, and acts as a tie-beam to, the extremities of the pillars of the arch. There is the additional important difference from an ordinary arch that equilibrium is seldom long maintained, the line of weight which falls upon the astragalus being liable to continual shifting by the raising of one or other of the pillars of the arch during progression. In the ordinary "standing" position, no doubt, the weight is distributed to the two pillars of the arch directly from the astragalus, and indirectly from the calcaneo-scaphoid ligament which receives a part of the weight directly from the astragalus; and the weight is borne about equally by the two pillars. In the third stage of the step, however, when the hinder pillar of the arch is raised by the calf-muscle, which, through the tendo Achillis, acts in the plane of movement of the ankle—a plane that is passing through the os calcis, the middle of the ankle-joint, and the space between the two inner metatarsal bones,—the weight is thrown more forwards, through the head of the astragalus, upon the calcaneo-scaphoid ligament; and that ligament is now severely tried, being thus subjected to much pressure and at the same time to much tension through the pull upon the heel. At this juncture the muscles of the sole come to its relief. Especially so does the tibialis posticus, which, by its strong tendon underlying the ligament and the head of the astragalus and attached to the scaphoid tubercle, the three cuneiform, the cuboid, and the three middle metatarsal bones, assists to support the astragalus and braces the arch and the calcaneo-scaphoid ligament at the very moment when it is co-operating with the calf-muscle in raising the ankle, and throwing the weight upon the ligament. The action of this muscle is therefore very important in contributing to lessen the strain upon, and in giving support to, the calcaneo-scaphoid ligament, at the same time that by raising the ankle it is causing the strain and increasing the weight. The peroneus brevis and peroneus longus have a similar effect in raising the outer ankle and strengthening and steadying the ankle-joint and the plantar arch. The former, through the medium of the leverage afforded by the projecting proximal process of the fifth metatarsal bone, resists the inward tendency of the balls of the toes; and the latter, attached to a similar process of the first metatarsal, braces the under part of the sole, while it throws the weight over the ball of the great toe in the final stage of the step.

A further complication, and an important difference from the ordinary construction of an arch, and a source of weakness in the foot, is the mobility of the bones upon one another, the mobility being greatest between the scaphoid and astragalus, where, as we have just seen, the strain is greatest. The provisions for this movement necessitate the presence here of a ball-and-socket joint, which is ill adapted to bear weight, and which throws the work of resistance to displacement mainly upon the subtending calcaneo-scaphoid ligament. There is probably no structure of its kind in the body which has more arduous duty than this ligament, a duty associated with the high development of the human foot, and the perfect fulfilment of which is requisite for the steady and complete accomplishment of the step in walking. Some mechanical advantage is derived from the slight *out*ward curve of the inner border of the foot between the point of the heel and the head of the first metatarsal bone. This has relation to the direction of the line of weight from the leg upon the foot, which is slightly *in*wards as well as downwards and forwards when the foot is planted upon the ground; and a further resistance to this inward pressure is furnished by the coalescence of the anterior fibres of the deltoid ligament with the inner part of the calcaneo-scaphoid ligament.

The astragalo-scaphoid joint, being a ball-and-socket joint, would permit movement in any direction, but the movements are limited and determined by the ligaments and by the form of the articular surfaces of the calcaneo-cuboid joint with which it is associated, the two forming practically one joint, resembling a hinge-joint; and the movements are thus reduced to flexion and extension, which take place upon an oblique axis, passing from within downwards and outwards through the middle of the ball of the astragalus and the fore part of the os calcis. When the foot is raised from the ground this joint is flexed, and the two curves in the sole which have been mentioned—that with the concavity downwards and the slighter one, along the inner side of the foot, with the concavity outwards—are deepened. When the foot is placed on the ground the opposite condition is produced: the joint is extended, and both curves are lessened—that is to say, the foot is in some degree flattened along the plantar aspect and also along the inner side. The extent to which this takes place depends upon the weight which is thrown upon the astragalus from the leg and the measure of resistance offered by the subtending ligaments and muscles. During these movements of flexion and extension at the middle tarsal joint, associated with the raising of the foot from the ground and the placing it upon the ground, the fore part of the os calcis as well as the proximal or hinder part of the anterior pillar, consisting of the scaphoid and cuneiform bones, rise and fall; and the joints between the astragalus and the os calcis permit the latter bone to move a little obliquely beneath the former, this being requisite for the maintenance of the proper level of the trochlea of the astragalus. Now, if the flexion of this mid-tarsal joint be abnormally excessive or persistent, the double curves are preternaturally increased, and we have the

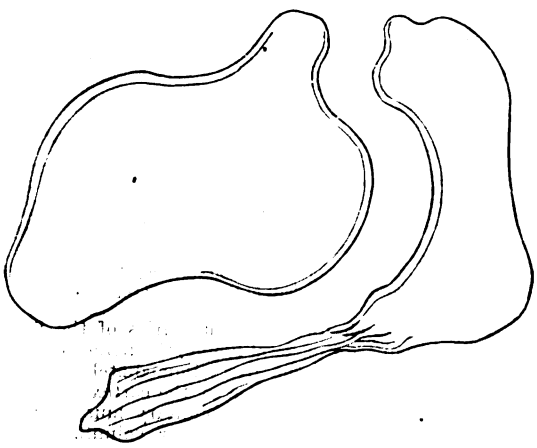
Digitized by Google

condition called "talipes cavus." If, on the contrary, the extension be exaggerated and persistent, the curves are lost, the sole is flattened beneath and is also flattened or bulged on its inner side, and the condition called "talipes valgus" or "flat-foot" is produced.

It may be further remarked that as in the variations upwards and downwards of the chief plantar curve the proximal parts of the plantar arch take their part, and the joints between the astragalus and the os calcis minister to this, so in like manner are the pillars of the arch affected and the calcaneo-astragalar joints concerned in the slighter lateral variations of the lesser or *out*wardly-directed plantar curve. Hence in the bulging of this curve inwards, which occurs in flat-foot, the os calcis and the components of the anterior pillar are inclined inwards, and the astragalus is carried inwards, in many cases so much that the trochlear surface is placed quite internal to the plane of traction of the tendo Achillis, instead of having its middle point in that plane. It is obvious how great a source of weakness this must be.

The interest, therefore, in the mechanism of the foot concentrates itself about the head of the astragalus, and the manner in which, in different positions, it is supported by the calcaneo-scaphoid ligament and the tendon of the tibialis posticus. This part bears a large amount of weight in standing, and has the chief weight thrown upon it in the several stages of the step in walking, more particularly when the foot is planted on the ground and when the heel is being raised from the ground; and the line of weight, especially if the toes be directed outwards, is *in*wards, as well as downwards and forwards. Hence in prolonged walking or standing, when the muscles have become fatigued and the tibialis posticus fails to afford its wonted support and brace, and the strained ligaments yield, the head of the astragalus, and with it of course the entire astragalus, gradually inclines more and more in the direction downwards, inwards, and forwards, the sustentaculum tali and the scaphoid bone are separated and descend, and the tarsal arch is lowered and bowed inwards. Further—and this is a very important change in a mechanical point of view—the trochlear or weight-receiving surface of the astragalus, instead of being in the plane of action of the calf-muscle and tendo Achillis—viz., in a line between the point of the heel and the interval between the inner two metatarsal bones—comes to occupy a position internal to that plane.[1] The dropping of the arch, being attended with a distancing of the two points of support, will cause slight lengthening of the foot, which will be somewhat lessened by the bowing of the arch inwards. Here let it be remarked that this change is peculiarly likely to occur during the growing period, when the structures are imperfectly shaped and formed, and when, inasmuch as shape is continually altering, they are ill fitted to bear any one position if prolonged, and especially if they are weighted in that position. The free-and-easy movements, the restlessness or fidgetiness, indeed, of the young is a provision against this source of deformity in the several parts of the body. Unfortunately, owing to the long-continued sitting posture enforced by the usages of civilisation, this provision is too often lost to the spine of the school-girl; and in the enforced standing of young persons in service or shops it is too often lost to the foot of growing boys and girls, to say nothing of the additional trials by weight-carrying and fatigue to which this ill-used part is subjected in errand-boys and many others. No wonder that not simply do the ligaments yield, but that the bones of the foot become deformed, as we find to be the case in the spine in lateral curvature and in the femur, if not in the tibia, in knock-knee.

If now we examine the specimen before us, we see that the middle part of the arch is lowered and bowed inwards. The whole of the key-bone, or astragalus, and the adjacent parts of the pillars—viz., the fore part of the os calcis and the scaphoid with the cuneiform bones—are below their proper level, and form a marked convexity on the inner side of the foot. The heel-bone slants from behind, not, as in the normal condition, obliquely upwards and a little *out*wards, but *in*wards and only slightly upwards. Hence the sustentaculum tali, the head of the astragalus, and the scaphoid tubercle, which should be scarcely seen from behind, form marked prominences on the inner side. The os calcis is moreover inclined over to the inner side—that is to say, has undergone a certain amount of super-pronation,—so that the outer tubercle at the heel is at some distance from the ground. The extremity of the fibula is nearly in contact with the upper surface of the os calcis, but does not actually touch it; and the calcaneo-cuboid joint is in a state of forced extension. With regard to ligaments, the fibres that have undergone most change are those that form the inner part of the calcaneo-scaphoid with the adjacent or continous portion of the deltoid. These are much stretched over the bulging head of the astragalus in the enlarged space between the inner malleolus and the sustentaculum tali behind and the scaphoid tubercle in front. The under and outer part of the calcaneo-scaphoid ligament is somewhat stretched and thinned, but otherwise little altered. The remainder of the deltoid ligament, the three parts of the external lateral ligament, the interosseous ligament between the os calcis and the astragalus, and the calcaneo-cuboid ligaments are all rather thin, but not much altered.



Removing the tibia and fibula, we notice that the trochlear surface of the astragalus, the facet for the internal malleolus, and that for the external malleolus, are all somewhat restricted from before backwards, indicating that the movements of the ankle-joint, which consist only of flexion and extension, were rather limited. This is particularly marked in the case of the facet for the fibula, which is devoid of cartilage in its anterior third. It is also observable that the outer margin of the trochlea does not rise so high as usual, which explains the circumstance, before difficult to understand, that the vertical line of the leg-bones upon the astragalus and the foot was maintained, although the heel-bone was, as just stated, rolled over to the inner side, or super-pronated. This subsidence of the outer edge of the trochlea appears to be due to a hyper-rotation of the astragalus upon the os calcis, an excess of that movement upon a vertical axis, or rather upon a slightly oblique backward and downward axis, whereby, as I have mentioned, the astragalus and the os calcis are accommodated to one another during the variations of the plantar arches. The effect of this hyper-rotation has been to turn the hinder margin of the astragalus slightly outwards, the anterior part or ball a little inwards, and the outer process—"processus fibularis," as it has been called—somewhat downwards and forwards upon the upper surface of the os calcis, or rather upon the outer part of the interosseous ligament, which normally intervenes between the os calcis and this process. In other words, there is a persistent condition, in an excessive degree, of the position which the astragalus assumes towards the os calcis when the foot is placed upon the ground and the plantar arches yield under the superincumbent weight. I say *persistent* condition, because the rotation in the opposite direction (that which in the normal state occurs when the foot is taken off the ground or is relieved of weight) was in this case abnormally restricted, the proper form of the part not having been resumable for a long time, probably for years. There is a well-marked articular facet upon the fore part of the processus fibularis, where it came into contact with the os calcis and the interosseous ligament. A facet in this situation is, however, not uncommonly present in the natural state of the parts. The articular surfaces between the astragalus and the os calcis presented nothing obviously abnormal. The greatest changes, however, are in the articular surfaces of the astragalo-scaphoid joint, in the ball or convex fore part and neck of the astragalus, and in the socket or concave part of the scaphoid bone. This joint had long been maintained in an over-extended position, and very little movement could be effected in it. The uppermost part of the convex surface of the astragalus, which is usually very pronounced, has been thrown back—pressed back—towards the trochlea, and raised into an eminence by some heaping up of bone on the adjacent portion of the neck; and it presents in front a small flat, or slightly concave, articular surface, upon which a corresponding facet on the upper part of the scaphoid impinged. The convex anterior part of the astragalus below this rested in a preternaturally deep concavity of the scaphoid; and the inferior and inner part, thinly and unevenly covered with cartilage, was in contact with the expanded calcaneo-scaphoid and deltoid ligaments. By these changes in the form of the articular surfaces the ball-and-socket between the astragalus and scaphoid is deepened and lessened in area, and is surmounted by and continued into a flat or arthrodial portion, which restricts, and indeed almost prevents, movement between the two bones. This is the only deviation from the natural conformation in the bones of the foot which is worthy of notice; and I think there can be little doubt that it is a

[1] On this and other points relating to the subject see a valuable paper on "Acquired Flat-foot," by J. Symington, M.B., in the Journal of Anatomy and Physiology, xix., 53.

Digitized by Google

consequence, and not a cause, of the deformity, being due to an alteration in the direction of pressure induced by the lowering of the plantar arch which resulted from a yielding of the ligaments. It may be observed, indeed, that the alteration in the bones is of such a kind as to prevent rather than favour a further increase of the deformity. At the same time it would have been an obstacle to the return to the natural position, which in so advanced and long-standing a case, and with such alteration in the articular surfaces, could not have been effected without osteotomy, if at all.

Flat-foot is sometimes spoken of as a condition of *hyper-pronation*, but not quite correctly, for it is not that necessarily, or indeed essentially; at least, that is not the main feature of the deformity, the inner edge of the foot and the great toe not being usually turned down as they would be in hyper-pronation. It really consists, as I have shown you, and as you may judge for yourselves in almost any case, in a persistent, over-extended, and incurved condition of the middle and chief joint of the tarsus; and it is due to a wearying of the muscles, more particularly the tibialis posticus, and a stretching of the ligaments, more particularly of the inner part of the calcaneo-scaphoid, with the confluent fore part of the deltoid and the calcaneo-cuboid. The altered direction of the pillars of the tarsus and the pronation of the heel-bone are, as we have seen, necessary sequences, or rather accompaniments; and the lowering and incurvation of the arch, together with the passage of the astragalus internal to the plane of action of the calf-muscle, seriously weaken the foot, and

lessen the ability to complete that important stage of the step which consists in using the ball of the great toe as a fulcrum for the action of muscles whose function it is to raise the heel and the ankle. Alteration in the form of the bones may follow from continued undue pressure upon certain parts, as in the upper part of the ball of the astragalus in the specimen before us. (See engraving.) But this cannot, usually at least, be an early feature; for in incipient stages of the condition the parts readily assume their natural relations when the weight is removed, which could not be the case if the bones had undergone a change of form. In the early stages relief from weight and muscular exercise of the foot will effect a cure. In the later stages, especially if such bone-deformity as we have witnessed have taken place, nothing short of an osteotomy will do good.

There is another point in the pathology of flat-foot I would mention. It has relation to the muscles which fall into opposite conditions on the two aspects of the foot, both of which conditions add to the difficulty of relieving the deformity; and the one is apparently, to a considerable extent if not entirely, induced by the other. The muscles on the tibial and flexor aspect of the foot become relaxed and enfeebled, so that they fail to exert their proper contractile power and cease to afford their proper support and to effect the normal movements of flexion and incurvation. Hence the antagonistic muscles—the extensors and the peronei,—not being duly stretched or extended, fall into a contracted and irritable condition, which in no small degree aggravates the deformity and the discomfort arising from it; and the condition is further increased, or it may in some cases be excited, by the demand made on them to steady and brace the tarsus when the foot is placed on the ground and the weight of the body is thrown over it. Their state is similar to that of the muscles on the outer side of the knee in cases of knock-knee, and of those occupying the concavities of the spine in cases of lateral curvature; and it is analogous to that of the flexor muscles in cases of disease of the knee and other joints. This state is relieved by rest, especially if the rest is combined with extension by means of a well-applied splint; but it soon returns unless the treatment is continued for a sufficient period.

Gulstonian Lectures

ON

SPASM IN CHRONIC NERVE DISEASE.

Delivered at the Royal College of Physicians of London, March, 1886.

BY SEYMOUR J. SHARKEY, M.B., F.R.C.P.,

ASSISTANT-PHYSICIAN AND JOINT-LECTURER ON PATHOLOGY AT ST. THOMAS'S HOSPITAL.

LECTURE I.

MR. PRESIDENT AND GENTLEMEN,—When I was informed that I had been nominated to fill the honourable position of Gulstonian lecturer for 1886 I consulted the records of the College in order that I might acquaint myself with the conditions attaching to the lectureship. I found that they were few in number, and that the main object which Dr. Gulston had in view was to secure, not only an annual dissertation on certain diseases, but also a practical demonstration of their pathological anatomy. It seemed to be incumbent, therefore, upon the lecturer to choose a subject which he could illustrate, however imperfectly, from his own experience, and I selected that class of chronic diseases which have this at least in common, that they are associated with muscular spasm. To you, who know the wide range of knowledge and the ample experience which would be required to treat such a subject exhaustively, this proposal must appear pretentious to the last degree. I am fully aware, however, that the limited time at my disposal, and still more the limited knowledge I possess, make an exhaustive consideration of it impossible. I merely propose to take a general view of chronic nerve disease in its association with muscular spasm, and to consider how far our present knowledge of pathology enables us to understand the phenomena which present themselves.[1]

By spasm is meant excessive muscular contraction; and, if we confine our attention to those muscles which are under the control of the will, excessive contraction is that which occurs in defiance of the will, or which, although commencing as a voluntary act, transgresses the limits which the will would impose upon it.

There is great variety in the spasmodic affections which have been observed in man, and to which descriptive names have been given. Thus, "tonic" spasm indicates persistent muscular contraction, a tetanic condition of a muscle or of groups of muscles, in which the individual waves of contraction overtake each other and are fused into one. "Clonic" spasm is a term applied to conditions in which the individual waves succeed each other less rapidly and often quite irregularly, giving rise to a great variety of intermittent spasms. The "coördinated spasms" form another class, in which groups of muscles are the seat of clonic contractions, which are coördinated in such a manner as to produce some regularly recurring though involuntary movement. It is unnecessary to proceed further in explanation of the many forms of pathological contraction of muscle which are embraced under the term "spasm"; they will be referred to again in connexion with the diseases which they accompany.

[1] I am indebted to my friend, Dr. Theodore Acland, for many of the microscopic preparations from which drawings have been made, and Mr. Shattock, Mr. Burgess, and Mr. Lapidge for most of the drawi

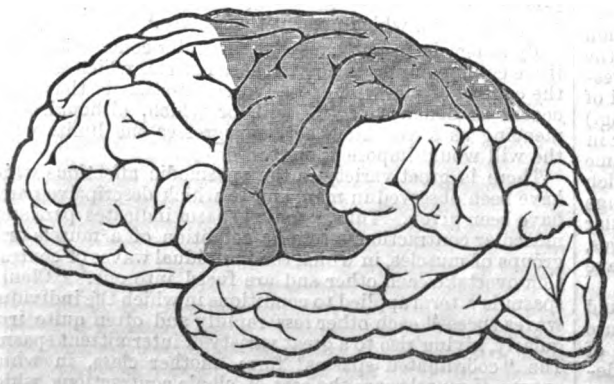
In health, as a rule, contraction of striated muscles depends on impulses transmitted to them through the nervous system and travelling down motor nerves; and the same may be said of that which is the product of disease; so that the motor nervous mechanisms afford a suitable basis, in connexion with which we may survey our present knowledge of the conditions which give rise to spasm. It is convenient, and I might almost venture to say scientific, to divide the motor mechanisms into a cerebral system and a spinal system; the latter forming a groundwork on which the former is superposed, comparatively late in the history of the development of the individual, and probably of the species. It might be thought that, considering the importance of the cortical centres of the hemispheres, of the central ganglia, and of the cerebellum, the term "cerebral systems" would be more appropriate than "cerebral system." But it is better, at any rate in considering spasmodic diseases, to embrace them all under one head; for our present knowledge of anatomy, physiology, and pathology does not justify us in concluding that there is any efferent motor connexion between the brain and the spinal cord except the pyramidal tract, direct and crossed, diseases of which give rise to muscular chronic spasm. Evidence in support of this view will appear in the course of these lectures.

The terms "cerebral system" and "spinal system" are intended to be anatomically exhaustive, and to comprehend all possible nerve mechanisms by which spasm is produced. There should be no room for any further division of the subject. But our ignorance, especially of the finer molecular changes which accompany not only abnormal but normal neuro-muscular conditions, during action and inaction, necessitates some reference to those spasms which are called functional, and which will, we may hope, with advancing knowledge, become amenable to a more accurate classification. The divisions of the subject, then, as now proposed are—(1) spasm in connexion with cerebral motor mechanisms; (2) in connexion with spinal mechanisms; (3) functional spasm.

1. SPASM IN CONNEXION WITH CEREBRAL MOTOR MECHANISMS.

The nerve fibres, which bring the voluntary muscles of the body under the control of the will, originate, so far as we know, in the central portions of the cortex. Experiments on living animals first yielded the clue to this discovery in man, and pathological evidence has abundantly corroborated

FIG. 1.



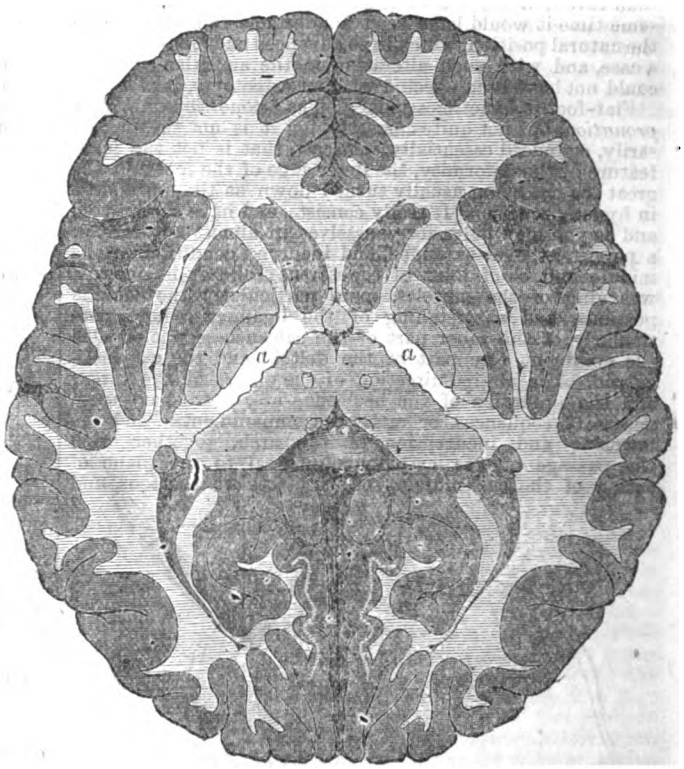


Diagram showing the position of the motor area of the cortex on the external surface of the brain.

the facts derived from this source. On an occasion like the present, it will not be thought a presumption if I refer to my own observations upon this point. In a paper published in THE LANCET of Sept. 29th and Oct. 6th and 13th, 1883, I recorded six cases of cortical lesions, all occupying the region in question, and all accompanied by motor paralysis, which occupied the face, arm, and leg, according to the localisation of the disease. It is unnecessary at present to enter into much detail on this subject. The two ascending convolutions which form the boundaries of the fissure of Rolando, the superior parietal lobule, the paracentral lobule, and probably some of the parts immediately adjacent to these, constitute the motor area of the cortex (Fig. 1). All we know about it, as regards voluntary muscular acts, is that the "way out" of the cortex for voluntary impulses passes through it. Some of the motor fibres are connected with processes of large ganglionic cells, which form a very striking feature of this region of the brain, and which resemble the cells of the anterior cornua of the spinal cord. The centres which are in connexion with the leg occupy the upper part, those which are in connexion with the arm the middle, while the lower portions, near the fissure of Sylvius, preside over the muscles of the face and tongue. During a part of the very long course which the fibres coming from the motor area pursue, the bundles on their way to the spinal centres for the face, arm, and leg remain distinct. Thus, passing from the cortex through the white substance of the hemispheres, they converge to the internal capsule, and occupy the knee and anterior two-thirds of its posterior segment, which lie between the optic thalamus and the lenticular nucleus (Fig. 2). In the capsule, the nerves for the face and tongue centres occupy the knee, the fibres for the arm come next, and those for the leg lie posteriorly. The knowledge of their relative positions in the internal capsule, which is a somewhat recent acquirement, is of great interest, because it probably affords at least part of the explanation of a long-observed clinical fact—namely, that in hemiplegia in connexion with disease of the central ganglia the arm is usually more paralysed than the leg. For hæmorrhages from the branches of the lenticulo-striate and lenticulo-optic arteries would from their position press more upon the anterior than upon the posterior division of the motor segment of the capsule.

Leaving the internal capsule, the fibres under consideration pass to the superficial part (basis) of the crus (Fig. 3), and there occupy its median portion, and are so placed that

FIG. 2.

Digitized by Google

the fibres presiding over the face are situated internally, those over the leg externally, and those in connexion with the arm centrally.

Arrived at the pyramids in the medulla oblongata, the fibres going to the spinal motor centres for the body and limbs decussate, those for the face and tongue having already done so a little higher up. It has been estimated that about 91 to 97 per cent. decussate; but the number probably varies within wide limits, so much so that there is good reason for thinking that in some cases complete decussation, in others none at all, takes place. Flechsig has also shown that in the same spinal cord the two sides may

FIG. 3.

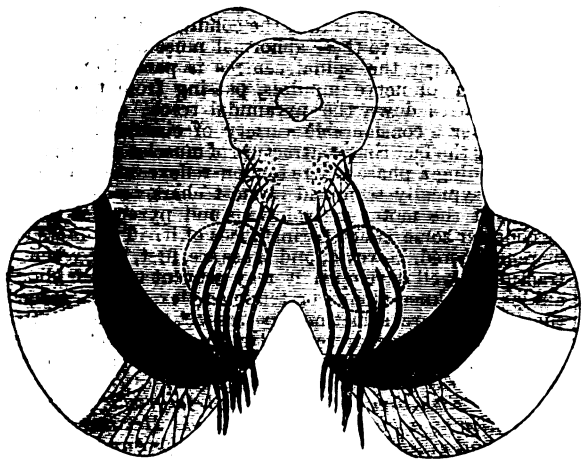

Diagram representing a vertical section through the crura cerebri. *a a* (unshaded area) show the position of the motor fibres from the motor area of the cortex.

be unsymmetrical in this respect. Some observers suppose that decussation of fibres of the pyramidal tract occurs in the cord, but nothing is known for certain with reference to this point. That part of the pyramidal tract which crosses at the decussation of the pyramids (the crossed pyramidal tract) occupies the posterior part of the opposite lateral column in the cord, being separated from the surface of the latter by the direct cerebellar tract. The fibres which do not decussate (direct pyramidal tract) pass down the cord on the same side, occupying a narrow strip along the margin of the anterior fissure (Fig. 4). The fibres of the

FIG. 4.

pyramidal tract finally form connexions with the multipolar cells in the anterior cornua of the cord, either directly or through the intermediation of other nerve cells.

It is a well-known fact that nerve fibres in general depend for their integrity upon connexions with ganglionic cells, and that when these are severed the fibres degenerate. Thus, the motor fibres of the cord depend upon the cells in the anterior cornua; the sensory fibres upon cells in the ganglia on the posterior spinal roots; while the healthy nutrition of the fibres of the pyramidal tract is dependent upon the cells in the motor convolutions. If their connexion with the latter be anywhere interrupted, or if the cells themselves be destroyed, degeneration occurs in the whole tract below. When this has taken place, tonic spasm supervenes in the muscles, which are, in health, under the control of these fibres. But between fully developed spasm and the earlier slighter indications of its presence there are many gradations. Taking, for instance, what is perhaps the commonest condition which gives rise to these events—namely, destruction by a sudden hæmorrhage of the motor portion of the internal capsule—it is often some months before well-marked spasm is observed; but in the meantime there are phenomena which foretell its coming. The most striking and frequent of these is the increased knee-jerk which a tap on the patellar tendon elicits. The knee-jerk may be diminished for some time after the apoplectic attack; but, if the fibres of the pyramidal tract have been interrupted, it soon becomes exaggerated. What are termed ankle-clonus and knee-clonus (phenomena which it is unnecessary to describe before an assembly like the present) soon appear, or may do so; for they are not necessarily present where the disease is slight. Charcot reports a case where ankle-clonus appeared eight days after the hemiplegic attack, and late rigidity began within three weeks; and another, in which it set in in one month, and late rigidity in two. Pitres gives cases in which clonus was observed in from eleven to fifteen hours. But in any case it may be said that increased tendon-reflexes and clonus precede rigidity; and, in many cases of chronic disease of the lateral columns of the cord, they are to be found a very long time before rigidity, or the latter may not set in at all before death occurs. Sometimes one tap on the patellar tendon gives rise to a succession of knee-jerks, and like phenomena may appear in the other limb, or in muscles still further removed. Brissaud asserts that even the non-paralysed side is not healthy, but presents in a certain degree these phenomena, which he terms "latent contracture." To what cause are these increased tendon reflexes to be referred?

Muscular tone is that condition of tension in healthy muscle which is, no doubt, due to nerve impulses proceeding from the cells in the anterior cornua of the spinal cord. A certain number of observers have come to the conclusion that the knee-jerk and other tendon contractions are local phenomena, due to direct contraction of the muscle, which is temporarily put upon the stretch by tapping its tendon. Its increase is due to the increased tension which results from severance of the spinal centres from the cerebral motor centres, which exercise a controlling power over those below, this severance producing increased muscular irritability. But for the tendon phenomena to take place at all the reflex arc producing tension must be intact.

Other authorities have convinced themselves, by equally careful observations, that the tendon phenomena are true reflex neuro-muscular acts. The objection to this conclusion, which appears insuperable to their opponents, is that the latent period is much too short for a reflex act. But surely it is not legitimate to bind all reflex acts by the exact laws which appear to govern skin reflexes. It is probable that conduction in nerves does not take place at precisely the same rate in every reflex arc in the body, nor even that the time required to reflect the afferent impulse on to the efferent nerve is uniformly the same. This will depend upon the purpose for which the muscular act is excited, and the speed with which it needs to follow upon the stimulus which evokes it. Now there are, as has been proved, nerve-endings in muscles and tendons; and it is not improbable that the slight stretching of the latter, which is produced by the action of antagonists, gives rise by means of a reflex act to the steadying action, which is always aroused by the contraction of opponents. This would require great sensitiveness on the part of the reflex arc; for, considering the suddenness of many muscular acts, the steadying contraction of the muscles not directly producing the movement would require to be almost equally sudden. If the muscular act which follows a tap on the patellar tendon be a purely local phenomenon, due to "myotatic irritability," it is difficult to explain those cases in which contraction of muscles in the opposite leg, or even in the arm, occurs. Gowers states that the latent interval for the knee-jerk is $\frac{1}{15}$ to $\frac{1}{30}$ sec., and that physiological data require that it should be $\frac{1}{75}$ sec. if it be a true reflex. But what will be said of the following equally legitimate argument? The interval for the knee-jerk is $\frac{1}{75}$ sec. Dr. de Watteville and Dr. Waller have found the interval for the jaw-jerk to be $\frac{1}{30}$ sec., which is only half the interval required for the knee-jerk. Therefore, the phenomena are not produced in a similar manner. Dr. de Watteville says

Digitized by Google

that Dr. Waller has determined the latency of the closure of the eyelids to the stimulus of a strong light to be $\frac{1}{20}$ sec., the shortest true reflex known. This differs much less from the interval for the knee-jerk ($\frac{1}{15}$ to $\frac{1}{10}$ sec.) than the latter differs from the jaw-jerk ($\frac{1}{10}$ sec.).

We know too little about the various reflexes which occur in the body to consider it as proved whether tendon phenomena are reflex or not; but it is at any rate satisfactory to feel that, for all practical purposes at the bedside, either theory is equally applicable; for the keynote to both is integrity of the reflex arc, and changes in the latter are necessarily accompanied by changes in the tendon phenomena.

Let us assume, provisionally, that the knee-jerk and other allied contractions are reflex. Why are they increased in disease which interrupts the continuity of the pyramidal tract, or destroys the motor cells in which its fibres originate? Probably the reason is, not that the descending sclerosis produces irritability of the cells in the anterior cornu, but, as Hughlings Jackson says, that the suppression of the functions of the pyramidal tract gives rise to "permitted hyperphysiological activity," the spinal centres being "let go." This view is strongly supported by those cases of congenital absence of the whole or a part of the motor centres in the brain which are accompanied by contracture of the limbs similar to that which occurs in lesions of the pyramidal tract resulting from disease, for in these cases the pyramidal tract has been proved to be deficient. This was the condition found by me in a case which I shall relate presently. The pyramidal tract is not developed until very late, and is not even complete at birth; and in the cases of congenital disease referred to it is not developed at all, or only in part. Even in disease which occurs in adult life and produces descending sclerosis, if the cord be examined after many years, the process of atrophy has long been completed, the nerve-fibres have disappeared, and nothing remains but a quiescent cicatrix. This was so in another case which I shall relate. In such conditions, no active process is going on to produce contracture; there is merely destruction of the pyramidal strands. Again, the exhaustion following upon the motor discharge in epilepsy may give rise to temporary increase in the knee-jerk or to ankle-clonus; and the same may be said of that suppression of function produced by the slighter degrees of chloroform narcosis. In short, the excessive tendon reflexes and contractions which result from descending sclerosis are merely evidences of abolition of the function of the cerebellar motor tract, which in health controls the action of the spinal ganglia.

Objections have been made to this view on the ground that sudden disease, such as cerebral hæmorrhage, which destroys the fibres of the internal capsule, does not give rise to the phenomena in question immediately, but only after the lapse of a certain time. The cases recorded by Pitres, in which ankle-clonus was observed to supervene in a few hours, prove that this delay is not an invariable rule; and even if it were, it would not be unreasonable to suppose that cells which have long been under the control of others should require a certain time before they learn to exert a power to which they have hitherto been unaccustomed. We may therefore look upon increased tendon reflexes, clonus, and contracture as degrees of independent neuro-muscular action, originating in the spinal centres, which have run riot owing to the diminution or annihilation of the inhibitory functions of the pyramidal tract.

But it may be further asked, Does the appearance of one or all of these phenomena prove that there is gross and tangible disease of the cerebral motor cells or fibres? The answer is, Decidedly not. In THE LANCET of Nov. 7th, 1885, Dr. Angel Money records his experience of "Reflex Actions, Knee-jerks, and Muscular Irritability in Typhoid Fever, Phthisis, and other Continuous Fevers"; and he shows that all the phenomena, except tonic spasms, are found in these conditions. But even contracture may occur in fevers. I have myself seen it in typhoid fever, and Dr. Murchison mentions its occurrence in typhus and relapsing fevers as well. Speaking of the former, he remarks: "Contraction and rigidity of certain muscles are observed more rarely, and only in severe cases. The fingers may be tightly clenched, or the forearm flexed, or, in rare cases, there is trismus or strabismus. In twelve cases I have observed tonic spasms of many different muscles. Twice I have seen the legs and thighs so bent that the knees almost touched the chin." A man, suffering from extreme debility and anæmia, came lately to my out-patient room, and the house-physician called my attention to the fact that he had not only very excessive knee-jerks, but as marked knee- and ankle-clonus as I ever saw. He was sent into the hospital, and after two days' rest in bed I was unable to elicit even the slightest clonus. Such cases as these, together with others in which recovery has occurred, justify the verdict which Dr. Donkin gives in *Brain* (October, 1885). "It seems clear," he says, "at present that we must bear in mind that we have not done with spastic paraplegia by calling it lateral sclerosis, remembering the cases which recover, whether they are quite obviously functional or not, but must believe with Friedreich, Wilks, and others, that the symptoms may occur under various forms of disorder or disease of the nervous system."

My own impression is that the condition which most frequently gives rise to these abnormal muscular conditions in connexion with the spinal centres is partial or complete suppression of nerve impulses, passing from the cerebral motor centres down the pyramidal tract; and this may occur under a considerable variety of circumstances. But accepting the fact that contracture of muscles accompanying or succeeding a phase where tendon-reflexes are exaggerated is most typically seen and is most characteristic in gross disease of the motor convolutions and pyramidal tract, let us consider some concrete instances of it. Two facts must be remembered, however, and these are, first, that when contracture is well developed it may prevent us from eliciting ankle- and knee-clonus or tendon-reflexes; and, secondly, that contracture sometimes passes off, the muscles at the same time undergoing rapid atrophy and the reflexes being abolished. This occurs when disease of the lateral column extends to the cells of the anterior cornu.

Case of Embolism of the Sylvian Artery, which resulted in Absorption of a large part of the Right Hemisphere of the Brain, and which was followed by Paralysis and Rigidity of Limbs.—The complete history of the patient's illness and of the post-mortem examination is recorded in the Transactions of the Royal Medical and Chirurgical Society for 1884, and I shall not enter into much detail now. The case is an instance of extensive destruction of the cortex and central ganglia on one side, producing descending degeneration in the cord, together with the symptoms which are characteristic of that condition. E. J——, aged thirty-four, was admitted into Guy's Hospital on March 8th, 1876, under the care of Dr. Pavy. She had never had any serious illness, and, though married ten years, had had no children. Suddenly she was attacked with giddiness, faintness, and sickness, and had an epileptiform seizure. After four days she recovered consciousness, and found that she was paralysed on the left side, and had no sensation on that side of her body. On admission she was found to have ordinary complete hemiplegia and hemianæsthesia on the left side. She had, in addition, a systolic murmur, audible all over the cardiac area. About four months after the commencement of her illness she left Guy's Hospital with the left arm almost useless, but with very fair power in the leg. She had completely recovered from the hemianæsthesia. Seven years later, on March 7th, 1883, the patient, aged forty-one, was admitted into St. Thomas's Hospital, under the care of Dr. John Harley, with aortic disease and bronchitis. Dr. Hadden, the registrar, made the following note. "The fingers of the left hand are partially flexed on the palm, and decidedly stiff. The skin over the backs of the fingers is whiter and more glistening than it is on the right hand. The grasp on the left is feeble, and there is rigidity of the flexors of the forearm and arm. The tendon-reflexes are very brisk in the left, but are hardly obtainable in the right arm. The left leg is somewhat rigid, the patellar-tendon reflex brisk, and there is slight ankle-clonus. The tongue is protruded straight. Slight paresis is observed in the muscles on the left side of the face. There is no loss of sensation. On casual examination at the bedside, the left eye appears to be sound, and there is no hemianopia or colour-blindness. Tested with a watch, hearing is found to be sharp, and equal on the two sides." The patient died somewhat suddenly on May 17th. The husband informed me that from the period of her attack, seven years before her death, she had been weak-minded and queer, doing unaccountable things, such as she had never done before, but that she remained a good-tempered, hard-working, and affectionate wife. On post-mortem examination, marked aortic disease (ulcerative endocarditis) was found, and there was great cardiac hypertrophy, the heart weighing 17½ oz. The lungs were hyper-

Digitized by Google

semic and œdematous at the base, and the lower portion of the right was semi-solid. The liver showed slight congestion in the centres of the lobules ("nutmeg"). The kidneys weighed 11 oz.; the capsule was thick and adherent, the substance very firm, and the surface granular. The spleen was hard and its capsule thick. In the right hemisphere of the brain the parts supplied by the middle cerebral artery were extremely wasted, and many of the convolutions had entirely disappeared. The central ganglia, too, were so much affected that the measurement from their intra-ventricular aspect to the outer surface of the convolutions of the island of Reil on the right, was not much more than one-third of that on the left. Descending degeneration of the lateral column, and also of the column of Türck, could be seen in the spinal cord; and the alteration in both these strands of fibres was situated on the side opposite the diseased hemisphere.

This case, the brain of which is now shown, together with drawings of microscopic sections of the spinal cord (Figs. 5, 6, 7), is of interest, not only because of the long time the patient lived after such extensive destruction of one hemisphere, but also because it is an instance of total decussation of the pyramidal tract. It will be seen on examination of the sections of the cord that the left half is very much smaller than the right, and that the white substance bordering on the anterior fissure, the column of Türck, is decidedly smaller on the left than on the right; that is to say, there is no direct pyramidal tract, but the whole of the fibres from the right hemisphere appear to have crossed, and to have gone, some into the left lateral column, some into the left column of Türck. On microscopic examination of the sclerosed tracts, there is seen simply diminution in the number of white fibres, and increase in the density of the neuroglia in the affected lateral column. Apart from the irregularity which exists in the columns of Türck, there is very little structural difference to be made out in them. The softening, which produced hemiplegia and subsequent rigidity in this instance, involved the cortex, central ganglia, and internal capsule.

Lesions need not, however, be so extensive in order to give rise to paralysis with rigidity. Destruction of a portion of the motor convolutions, or of the subcortical fibres connected with them, or of that part of the internal capsule through which the motor strands pass, produces the same phenomena. Cases of softening of portions of the cerebral cortex of long standing do not often come under the observation of pathologists in the post-mortem rooms of general hospitals; or, if they do, I have been singularly unfortunate in not meeting with them. A girl about eleven years of age, who was under my care as an out-patient at St. Thomas's Hospital, had had a very severe burn on the right side of the head when she was two years old. The scar occupied the greater part of the parietal region, and it was perfectly destitute of hair. I got no very clear details of the symptoms which succeeded this accident, except that she lost power all down the left side, a condition from which she had never recovered. Since then she had been subject to epileptic fits, in which the left side was convulsed; but she did not lose consciousness. The arm when I saw her was rigidly contracted, the leg being much less affected, and the deep reflexes were excessive all down the left side. Now, although the actual state of things was not demonstrated by a post-mortem examination, it is pretty certain that the burn caused superficial disease of the parts situated immediately below and within the cranium, and destruction of a portion of the motor cortex, with descending degeneration of the pyramid of the tract, was the result.

Case of Perforating Tuberculosis of the Skull, with Cerebral Symptoms.—In *Brain* (April, 1885) Dr. Edmunds describes a case which affords a good instance of descending degeneration and rigidity from a limited cortical lesion. The patient was a boy of fourteen, of a delicate family. Eighteen months before admission into St. Thomas's Home he had suffered from what was supposed to be tubercular peritonitis, and at the same time an abscess, accompanied by much headache, formed in the region of the left parietal bone. About six months later he complained occasionally of numbness in the right arm and hand, and two days before admission he had his first fit. He felt giddy, fell, became unconscious, foamed at the mouth, bit his tongue, and passed urine involuntarily. Both legs were convulsed, the right arm flexed, and the right hand clenched. He was admitted into St. Thomas's Home on Sept. 3rd, 1884. An abscess was found situated over the left parietal bone. The grasp of the right hand was much weaker than that of the left, and there was very slightly deficient power in the right leg and right side of the face. Sensation was everywhere normal, but double optic neuritis was present. I saw the patient with Dr. Edmunds at this time, and subsequently the abscess was laid freely open and a piece of dead bone removed, so that the dura mater was exposed and the pulsations of the brain could be seen. After this he had two fits, much like the one already mentioned. The discharge from the opening in the skull gradually diminished and the scalp covered over the edges of the wound, so that when he left the hospital there was a defect in the skull and scalp, through which the dura mater could be seen. A silver plate was made to protect this. On Feb. 4th, 1885, he left the Home, the chief symptom of disease which he presented being partial paralysis of the right arm and hand; when tested with the dynamometer, the right hand only marked twenty, the left seventy.

(To be concluded.)

ON SOME

MODERN REMEDIES IN HEART DISEASE.[1]

BY A. ERNEST SANSOM, M.D. LOND., F.R.C.P.,

PHYSICIAN TO THE LONDON HOSPITAL, CONSULTING PHYSICIAN TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN, LECTURER ON MEDICAL JURISPRUDENCE AND PUBLIC HEALTH AT THE LONDON HOSPITAL MEDICAL COLLEGE, ETC.

THE purpose of this communication is distinctly practical. It is not to discuss the probable therapeutic position of agents of quite recent introduction, but to apply the test of practical experience to some remedies which have not come into general employment in the treatment of diseases of the heart but which have been, in my opinion, sufficiently investigated for the formulation of some valuable lessons. I propose to consider the two agents caffeine and convallaria majalis, and to place on record as succinctly as possible my experience of their effects in cases of mitral disease. We all know that it is dangerous in therapeutics to be too positive, and that in investigation it is impossible to be too careful. We cannot have mathematical precision, because it is impracticable to group similars. I have, however, distinctly divided the cases of mitral stenosis from those of mitral regurgitation, and the importance of such separation will presently be seen.

I.—MITRAL REGURGITATION.

We will first consider the conditions and the nature of the cases with which we have had to deal. We must all be convinced that though structural disease has rendered the closure of the mitral orifice in systole imperfect, such a state of things may be quite harmless and unattended with symptoms. It is true that an extra strain is put upon all the muscular chambers of the heart, but we know from cases which have been quiescent and symptomless for many years that the lesion can be balanced by an increased development and some enhanced energy of the cardiac muscle. The cases do not present themselves till compensation is disturbed or some new phenomena have arisen. Such disturbance is manifested in different modes in different patients. In one there will be palpitation, irregularities of heart's action, oppression at præcordium, heaving impulse or troubles directly referred to the heart itself; in another difficulties of breathing, variable, but increased by exertion; in another dyspeptic ailments and the results of venous congestion of viscera; in a third the gradual oncome of dropsy. Or the failure of compensation may be first evidenced by an acute attack of inflammation of the lung. We find in such a patient pyrexia, dyspnœa, and the physical signs of a limited pneumonia. On examining the heart we obtain evidence of mitral regurgitation. Then the clinical history teaches us that the pneumonia presents characters which differentiate it from the forms which we observe in those who are not the subjects of cardiac disease. The outline of percussion dulness is clearly defined, often wedge-shaped; the signs indicate the density of a lung affected with croupous pneumonia, but not the extent of area involved in such a case. The sputum differs from the rusty viscid

[1] Read before the Harveian Society, February 18th.

Digitized by Google

material of ordinary pneumonia; it is frothy, and in many cases, having continued thus for a day or two, is suddenly found to be bright with florid blood. These signs indicate infarction of a branch of the pulmonary artery, and they may be the first sign which demonstrates to us the failure of compensation in cases of mitral regurgitation. In the enfeebled right heart coagula have formed, which, projected into the pulmonic arterioles, have given rise to the symptoms I have mentioned and to the appearances which, when discovered at the necropsy, have been in some cases designated pulmonary apoplexy. These, then, are among the signs which, when met with in a given case, announce to us that compensation is disturbed. We may have opportunities of watching the downward course: how the left ventricle becomes more and more dilated, how the right chambers yield also, and the venous system becomes engorged—a lesson, perhaps, pointed by the increasing size of the liver, as well as by distressing signs of dyspepsia; and then, how the over-dilated right ventricle permits regurgitation through the tricuspid orifice. This is a slight sketch of the occurrences when a heart affected with an imperfect mitral valve, permitting regurgitation through the mitral orifice, begins and continues to fail on account of the inadequacy of its muscle to overcome the difficulties. But these are by no means all the circumstances with which we may have to deal in any given case. There may be engrafted difficulties: the fires of the old endocarditis may be relighted, pericarditis may be manifested, and in both these conditions, I consider, myocarditis, which of course tends extremely to enfeeble the muscle, is in some degree an almost constant concomitant; or pleurisy, a frequent association with cardiac cases, may occur; or affections of other organs, especially the kidneys, may increase the dangers. Such are the difficulties which we are called upon to endeavour to overcome by treatment. Now, leaving all questions of general management, what are the special drugs on which we can rely?

1. *Digitalis.*—This is our first resource, and nearly all our patients are treated by it when faults of compensation are announced to us. There is yet some lingering of the old timidity which, regarding digitalis as a sedative and depressant of the heart, would withhold it when the heart is weak. Accurate investigation has shown that digitalis increases the force of the cardiac muscle and tends to cause the arterioles to contract, by a combination of these actions raising the blood-pressure within the arteries.[2] In a large majority of cases the careful administration of digitalis, combined with measures to promote a good general nutrition, when the early signs of imperfect compensation present themselves in cases of mitral regurgitation, is followed by such good results that it is unnecessary to seek for another agent. After a short period compensation may be restored, and then only general tonics and good dietary and management may suffice to maintain it. In a very considerable number of cases of mitral regurgitation, however, small doses of digitalis may be continued for long periods. My experience quite agrees with that of Dr. Broadbent, who says: "In mitral incompetence digitalis may be given almost indefinitely, and patients often take it for years with obvious advantage."[3] It is quite otherwise in mitral stenosis, as we shall see hereafter. What, then, are the drawbacks to digitalis? They are manifest even in the early stages of failing compensation in a minority of the cases of mitral regurgitation. With some patients the drug does not agree and cannot be made to agree. It may induce faintness and sickness. In children sometimes vomiting is induced, and it cannot be persevered with. In other cases, though these symptoms be not manifested, the drug, instead of increasing the force and decreasing the rate of the pulse, actually increases the feebleness and the rapidity. In some the drug, instead of acting as a diuretic, diminishes the quantity of urine excreted, and in a few instances there may be insomnia, restlessness, and nervous disturbance. These signs of intolerance of digitalis in cases of mitral regurgitation are rare, but they are sufficient to make us cautious. It is, I think, a good rule, and one that I always adopt, never to give an adult a larger dose than five minims of the tincture (or its equivalent in infusion or the powdered leaves) three times a day for a longer period than a week without my observation. Then, if tolerance is assured, the patient may continue to take the drug, or the dose may be continuously increased. It is to be remembered that the effects of digitalis may last longer than the period of its administration. Mr. Raven of Broadstairs has recorded the case of a woman aged sixty-seven, with dilatation of the left ventricle and anasarca, in whom fifteen minims of tincture of digitalis administered every four hours for five days induced diuresis and the relief of the anasarca, but symptoms of intolerance (nausea and vomiting) showing themselves, it was omitted, effervescing salines being substituted. The pulse, which had been quick, weak, and irregular, became slower, and ten days after the suspension of the digitalis it had fallen to 40 per minute.[4] It is in the later stages, however, that the failure of digitalis is most marked. Its power of increasing the force of the left ventricle seems to be gone; the right cavities continue to dilate, dropsy may be manifestly increasing, and yet the agent in all combinations with ordinary diuretics fails to increase the outflow of urine. Then we turn perforce to other agents, such as

2. *Caffeine.*—This is the highly nitrogenised crystalline principle, occurring in colourless silky needles, obtained from coffee, tea, or guarana, and existing in other vegetable products—e.g., the kola-nut. Caffeine is said to be a stimulant of the medulla and cardiac centres, to quicken the pulse and respiration, and to raise the blood-pressure when given in moderate doses. It may induce irregularity and intermittency of pulse; it is classed as a stimulant of the cardiac muscle. It acts as a diuretic, though not invariably so.[5] A large number of observers have testified to the beneficial effects of caffeine in various forms of cardiac disease, but there has been by no means a consensus as to its value and as to its mode of action. Francotte found that whilst caffeine increased neither the water nor the urea excreted in the urine in health, it had a pronounced diuretic action in cases of cardiac disease. Riegel of Giessen concluded that it produces the best effects of digitalis upon the circulation, that it is more rapid than digitalis in its action, is not cumulative, and may be administered to the feeblest person.[6] The following is the recent utterance of Professor Jaccoud. The effects of caffeine "are identical with those of digitalis; slowing of the heart pulsations; augmentation of its force of contraction; diuresis; no nauseous effects; no cumulative action. This drug, therefore, does not necessitate an incessant watchfulness. You can employ it in cardiac cases where the kidneys are affected."[7]

As to mode of administration. Pure caffeine is soluble in from 80 to 100 parts of water: its solubility is increased by acids. I have generally employed the citrate, which is freely soluble. It has been objected that this is a doubtful salt, but this objection is of small importance if the proportions of caffeine and citric acid used in its manufacture are definite, the only important function of the acid being to render the salt easy of solution. I employ it in from three-grain to five-grain doses, dissolved in the ordinary saline mixture—diluted liq. ammoniæ acetatis. The dose is generally administered three times in the day, but in some cases once only. Instead of the citrate, the pure caffeine may be employed, dissolved in solutions of benzoate or salicylate of sodium; in these it dissolves freely, and thus a concentrated solution may be made for hypodermic injection. The following is a good formula for internal administration: Pure caffeine and benzoate of sodium, of each one drachm; distilled water, six fluid ounces. Half an ounce contains five grains of pure caffeine.

LEEDS GENERAL INFIRMARY.—The annual meeting of the governors of and subscribers to this institution was held on the 1st inst. The number of in-patients admitted during the year was 4154, against 3807 in the preceding year, showing an increase of 347. The daily number of beds occupied was 250, against 230 in the preceding year, and the average duration of treatment of each patient was twenty-one days. The rate of mortality was 4·93 per cent., but, deducting forty-seven patients who died within forty-eight hours after admission, the percentage is reduced to 3·90. During the previous year the rates were 5·34 and 4·18 respectively. The number of out-patients admitted was 19,106, against 16,730 in the preceding year, showing an increase of 2376. The total amount of expenditure was £16,510.

SAVING CONDEMNED LIMBS.

BY SAMPSON GAMGEE, F.R.S.E.,
PRESIDENT OF THE BIRMINGHAM MEDICAL INSTITUTE.

A SURGEON'S responsibilities are probably never more delicate and weighty than when he is called upon to review a decision to amputate a limb. To the cases elsewhere published,[1] in which, from inability to coincide with proposed amputations, I have successfully adopted measures to save limbs, brief notes of a more recent case may be added preliminary to comment.

In compliance with an urgent call into the country I visited a patient whose leg was to be amputated next day. I gathered from the medical attendant that a fracture through the right ankle had occurred about a fortnight previously; great swelling having supervened, a considerable number of leeches were applied, and then padded wooden splints. When these were removed, after four or five days' intense suffering, a large wound was exposed on the inner aspect of the limb, which was much swollen. Splints were then discontinued, carbolic acid lotion applied, and amputation advised after consultation with a hospital surgeon.

I found the limb from foot to knee greatly swollen and tense, of deep red colour, and exquisitely sensitive to the slightest touch. The skin, to the extent of several square inches over the tendo Achillis and on the outer part of the leg, threatened disorganisation; and on the inner side of the ankle was an irregularly shaped deeply excavated wound, measuring from side to side five inches and five-eighths, from above downwards three inches and seven-eighths, and seemingly penetrating in its depressed centre into the ankle-joint. The patient's constitutional state was sound, but pain and want of sleep had produced considerable exhaustion. Unable to concur in the proposed amputation, I advised twenty-four hours' delay to test the effect of the treatment which I proceeded to carry out. Carefully supporting the limb, I raised the foot and placed on the outer side, from the lower third of the thigh downwards, a double millboard splint, gummed, and padded three inches thick with dry absorbent gauze and cotton tissue. The splint embraced the sole of the foot which, as well as the whole inner side of the limb, was padded with equally thick and perfectly smooth folds of the tissue. The whole was now smoothly bandaged with long spirals and without reverses, and with equable but decided pressure. Four six yard bandages were used. The limb was then placed on the outer side in a swing, and I visited the patient with the medical attendant the next day. Pain had been much less, and the loosened bandages denoted great subsidence in the swelling. Taking the limb out of the swing, the bandages on the inner aspect were cut, and the absorbent tissue, soaked with a great quantity of matter, removed; but the millboard splint on the *outer* side was not touched for some days. The skin was paler and much less sensitive and tense. The same dressing was repeated on the following three days. The improvement locally and constitutionally was then so marked that the question of amputation was not reopened; and henceforward the dressing was only renewed every other day. A considerable slough separated from over the tendo Achillis and the outer part of the leg, and the absorbent tissue before application was lightly sprinkled with some of the following lotion: Four grains of sulphate of zinc, half an ounce of methylated spirits of wine, one ounce of glycerine, and one ounce of water. The wound surface was occasionally touched with solid sulphate of copper. The dense deposit in the leg above the wound softened and gave evidence of subcutaneous pus, which was carried off by drainage-tubes, one of which was passed several inches up the inner side of the leg, by corkscrew movement, from beneath the upper edge of the wound. Another tube was introduced through a small incision just outside the middle of the tibia. The outer ends of the drainage-tubes were made to project out of the dressings into a tin tray containing dry earth, which could be changed whenever necessary. The more perfectly to immobilise the foot and ankle, a bracket millboard splint was secured on the outer side, so as to embrace the leg just below the calf, and also the outer edge of the foot. Later on, gummed millboard splints were placed on the inner and posterior aspects; and it may give some idea of the amount of padding to state that at each dressing half a pound of the absorbent gauze and cotton tissue was used. For the first six weeks the dressing was renewed every other day, after that on Mondays and Thursdays. The patient left her bed for the couch at the end of two months; in another fortnight she removed downstairs, and then the wound on the inner side of the ankle was solidly healed, with fair and steadily improving movement in the joint.

The recovery of the limb was due to a variety of agencies, chief amongst which were immobility, position, pressure, infrequent and dry dressings, with drainage by absorbent tissue glycerine and tubes. It was remarkable how the very tender limb, which at first could scarcely bear the lightest touch, became comfortable under equable elastic pressure, physiological position, and absolute rest. I have elsewhere[2] recorded a case in which a patient with a tender swollen leg, similarly treated, spontaneously expressed himself in these words: "It is wonderful how I can bear the limb handled now, and I could not stand a feather touching it last night." Glycerine in such cases acts as an antiputrescent, and by its great affinity for water powerfully aids absorbent tissues in securing perfect surface drainage, and keeping parts clean and sweet without the use of water. The plan of wound treatment, based on physiological principles, which I have enjoyed the frequent privilege of illustrating in these columns, was strikingly exemplified in the case above related. The limb was in such a condition that it was impossible to foretell its recovery with certainty, and it was only by the utmost care at every dressing that the result was attained. But I was from the first hopeful. In a large proportion of cases in hospital and private practice in which I have been called upon to amputate, I have not touched the knife and have spared the limb. A clear conception of physical and physiological principles, unprejudiced application and combination of therapeutic resources according to the circumstances of particular cases, gentle yet firm, painstaking yet not meddlesome, manipulation, are very powerful agencies in saving condemned limbs.

Birmingham.

ON A CAUSE OF UTERINE DISPLACEMENT, NOT HITHERTO MENTIONED, CONTRA-INDICATING THE USE OF PESSARIES.

BY J. BRAXTON HICKS, M.D. LOND., F.R.S., F.R.C.P.,
CONSULTING OBSTETRIC PHYSICIAN TO GUY'S HOSPITAL, ETC.

I WRITE subject to correction, but I believe the cause about to be mentioned of uterine displacement and flexion has not been remarked upon, and yet it is not so very rare. Briefly stated, the concavity of the abdominal walls, noticeable in many spare women, will not permit the uterus to take its proper position in the pelvis, but, acting chiefly through the agency of the bladder more or less upon its fundus, pushes this portion back towards the promontory of the sacrum in a much more marked manner than occurs in a normal state, ending in flexion if the uterus be soft and its attachments to the front of the pelvis fairly firm. Again, if the uterus be tied by adhesions, or be already anteverted more than usual, then this condition is still more increased, and the bladder, unable wholly to rise above the uterus, expands by one arm of its Y-shaped cavity in its empty state above it, thus pressing the fundus down, and the other arm distending beneath the uterus tends to increase the anteversion, pushing up the lower end, thus increasing in two ways the anteversion. So that if the catheter be passed the fundus will be found projecting into the back of the bladder and closely opposite to the sphincter, preventing it easily entering, while it readily passes above and below to the full extent, and thus the functions of the bladder are materially interfered with. As most of these cases occur in single women, the uterus is generally held to the pubic segment of the pelvic floor

[2] Wounds and Fractures, p. 187.

Digitized by Google

fairly firmly; but in those who have been delivered the laxity of these front attachments permits the bladder to push the uterus backwards and downwards, so as to bring the back of the uterus in close contact with the anterior wall of the rectum.

In books of anatomy and obstetrics it is stated that the fundus of the uterus reaches to the level of the upper edge of the pubes. This may be taken as generally correct, though from clinical observation I should be inclined to say that it not infrequently rises a little above the plane of the conjugate. The abdominal walls, springing from the edge of the pubes, curve rather forward, and thus do not interfere with the distension of the bladder, at least not to any great extent; nor in the empty state of the bladder with the position of the uterus of normal anteversion; though when the bladder is full it retroposes the uterus towards the sacral promontory. In the condition, however, of the abdomen walls above alluded to, and described in my paper on Abdominal Tension[1]—namely, of extreme retraction,—the walls become concave and are in close contact with the brim nearly throughout, in some cases resting nearly closely on the anterior surface of the iliacus and psoas, pressing to a not unimportant extent the viscera, &c. And thus it will readily be understood how that, as the bladder is being distended, unable to rise upwards, it pushes the uterus back to a degree to be measured by the difference of distance between the present incurved line of the inner surface of the walls and their former normal state. The uterus thus in course of time assumes a position with its axis approaching that of the conjugate of the middle of the pelvic cavity, the os in the retroposed position being somewhat apparently elevated, but pointing forwards, except when, to a certain extent, it becomes flexed. There is not much space between the rectum and the back of the uterus, and when fæces accumulate, as they are apt to do in this starved state of the system, they are more or less closely in contact. As I have pointed out, the pressure the walls exert is considerable—some of it due, as it appears to me, to a kind of permanent contraction of the muscles. This retraction of the walls could not take place without the absence of gas in the intestines; possibly the more solid contact of the inner face of the walls against the firm structures behind sets up a kind of chronic spasmodic state.

I am inclined to think that the uterine dartoid-like attachments are in a state of irritability also. That they are at times capable of this action I have no doubt, and this serves to explain the varying opinions of those who have seen the same case at different times, and it has its parallel in the action of the homologous dartoid tissue which causes retraction of the testicle. That all this can occur without some sort of uneasiness would be wonderful, and this it is which leads the patient to seek medical aid. Generally the patient is of a neurotic temperament, ill nourished, badly feeding, and much complaining; nor is this perhaps to be wondered at, seeing that owing to this incurved state and pressure the abdominal viscera are displaced and interfered with in their movements and functions, thus producing uneasiness, often visible on the face. Accordingly the medical attendant necessarily finds it a difficult task to determine whether the ailment had originated in the uterus, as a cause of reflex bad appetite and nausea, or not. If the pelvic region is much complained of, or if the medical man is over-intent on uterine maladies, he would very possibly be led to examine the uterus, and, finding the organ out of place, might be led to think this the prime cause, and to attempt to correct the displacements by mechanical means. Again, if the digestive organs were most complained of, the cause of the pelvic distress might be overlooked, or attributed to ovarian irritation, or to the constipation, to neuroses, or to fancy. Supposing, then, that in the course of treatment attempts are made by the medical man to correct the position of the uterus by pessaries, the same forces which pushed the uterus into that position he will find now to resist his efforts, and although he may be able to restore the organ in part and get the pessary into place, he will find it will not—as it cannot, indeed—properly act, and that the patient, instead of being relieved, is more uncomfortable.

The same remarks apply to both conditions whether retroversion or anteversion: so long as the abdominal walls remain in the same incurved state above described, it is difficult in most cases to elevate permanently the fundus; indeed, all attempts generally increase the distress, and the uterus shortly regains its former position.[2] In this retracted condition of the walls, the ovaries also along with the uterus suffer from the pressure and restraint of free movement, without which none of the viscera can work painlessly and perfectly; but when pessaries are employed, these are almost certain to be brought in contact with the ovaries, and consequently much distress is felt; and this is naturally most severe when rigid pessaries are used, such as are made of vulcanite, coralline, or metal—the kinds most likely to be used in these difficult cases. In some of these cases, it is probable that the uterus was already retroposed or anteposed—i.e., before the retracted state of the walls occurred; but the clinical aspect of the case is the same whatever the order of arrival. From a survey of this state of things I think it will be conceded that the uterus has assumed the position of neutrality to the forces existing about it, and that the treatment should rather be directed to remove these abnormal forces than to drive the uterus in antagonism to them, and thus place it, as it were, between the upper and nether millstone.

SEPARATION OF THE EPIPHYSIS OF THE CAPUT FEMORIS.

BY NOBLE SMITH, F.R.C.S. EDIN.,
SURGEON TO THE ALL SAINTS CHILDREN'S HOSPITAL.

THIS accident is doubtless extremely rare; in fact, the symptoms that were present in the few supposed cases that have been recorded were not sufficiently characteristic to be accepted as absolute proof of the nature of the cases. The subject is referred to in the third edition of Holmes's System of Surgery thus:—"Several supposed examples of this accident," writes Mr. Henry Morris, "have been recorded, but I agree with Mr. Holmes in thinking that they are not conclusive as to the real existence of this lesion." Mr. Morris refers to two cases.[3] Hamilton describes these and two other supposed cases, but does not consider any of them as proved.[4] The following, I believe, will be considered a clear instance of this lesion.

A delicate young lady, aged seventeen, nearly fell while walking on wet board boards, the right leg slipping outwards and forwards. She recovered herself, but felt severe pain, chiefly in the knee, but also in the region of the hip-joint. There was intense pain at the back of the knee-joint, which afterwards became more general. The pain in the hip soon decreased. A provincial surgeon of considerable experience, who saw the case, could detect no shortening of the limb, but the toes inclined outwards at about 30° from the vertical. The pain was referred to a spot just below Poupart's ligament. With perfect rest in bed the pain continued to lessen, and the patient was able to make some voluntary movements of the limb. The surgeon diagnosed "severe strain" of the femoral muscles from violent external rotation of the limb, with probably some rupture of the capsular ligament. About five weeks before this accident, the patient strained the right knee in walking quickly. With rest, this strain had apparently been recovered from, but it had probably left the muscles weak, and had thus contributed to the second and more severe accident.

When I saw the case on October 9th, 1885, eleven weeks had elapsed since the second accident. She had remained at rest in bed for three weeks, when, as the pain had ceased, she endeavoured to get up, but it was found that the right leg was quite useless. I found the leg measured in its length an inch and a quarter shorter than the other. Measured from the top of the trochanter to Bryant's line (a plan more convenient than Nélaton's for such a purpose), the same difference existed between the two sides. The right trochanter was slightly prominent laterally to an extent not greater than a quarter of an inch. The foot was rotated outwards to the extent of 50°; whilst in the recumbent position she could flex the thigh to an angle of 45° with the straight line of the body, without moving the pelvis. The leg was utterly useless to her for standing.

[2] It may be wise in some cases of anteversion to try if any benefit may be derived from retroposing the uterus; but this should be done by a sound rather than by a pessary.

Digitized by Google

as it would support no weight in this position. When the patient was placed on her side she could extend the thigh almost completely. When I attempted to rotate the thigh inwards, the toes could be turned an inch towards the vertical, but no further rotation could be effected without moving the pelvis. There was complete absence of pain in the hip when these movements were made.

The opinion which I formed of the case was as follows:—The first slight accident caused a sprain of the muscles surrounding the hip-joint, leaving them somewhat weak and favouring injury to the joint. At the time of the second accident, when the patient stumbled, the leg slipped outwards and forwards. Upon this latter occasion I believe the epiphysis was separated from the shaft, but was kept in position by the capsule, as occurs in intra-capsular fracture, and subsequently the bone became displaced by muscular action. It will not, I think, be doubted that the head of the bone was separated from the shaft. The trochanter being an inch and a quarter higher than that of the opposite limb, and the two trochanters on the same level with the front of the body, although the right one was rotated out while the left was held with the foot vertical, indicated one of two conditions: either the head of the femur must have been dislocated from the acetabulum, or, if it remained in its place, it must have been separated from the shaft. If it had been dislocated the head must have been discovered in the displaced position. In rotation outwards of a thigh the trochanter is naturally carried backwards, but here the trochanter was level with the other, and therefore the head of the bone would have been very prominent had there been dislocation. There was no sign of it. Assuming that the head of the bone was separated from the shaft, its production by disease of the joint was contra-indicated by the history, the symptoms, and the result of treatment.

Treatment.—The patient being placed under the influence of ether, I was able to flex the thigh upon the body nearly to a right angle. The movement of the joint in all directions was more free than before. While in a flexed position I applied manual traction to the thigh, rotated inwards, and brought the limb down to a straight line with the body. Very moderate force was required; a cartilaginous grating was felt to occur in the joint as the leg was brought down. It was thus placed in a position which was perfectly natural, except a very slight degree of shortening, certainly less than a quarter of an inch. The limb was fixed with a Liston's long splint, and kept so for six weeks. The joint was then found to be firm, but very restricted in movement—one may, in fact, call it anchylosed. The patient was allowed to move about with crutches for twenty-five days, using the foot slightly. She then discarded the crutches, and has since walked about comfortably. A mechanical support from the boot to the thigh and pelvis has been worn, and will be continued for a few months longer. The fixation of the joint might probably be relieved by forced movements; but I have thought it prudent to defer any such attempt until ample time has been allowed for repair to take place.

As an example of a rare if not unique accident, this case must be of interest. The result of treatment will also probably be considered fortunate, for the leg had been a useless appendage for eleven weeks before the reduction was effected.

Queen Anne-street, W.

A CASE OF PROLONGED RIGOR IN AN EPILEPTIC.

WITH REMARKS.

BY J. HARRINGTON DOUTY,

DEPUTY MEDICAL SUPERINTENDENT, WORCESTER COUNTY ASYLUM.

H. B——, aged seventy-five; epileptic since an apoplexy two years and a half ago; dementia. I was called the other day to see this patient, who was said by the charge nurse of the hospital ward to be in a rigor. The following note describes briefly the symptoms which presented themselves:—She was shivering from head to foot, like one who was in the early stage of an acute febrile illness; her teeth chattered violently; the skin was pale and in a state of "cutis anserina"; her face wore an expression of distress and anxiety; she groaned at times and complained of violent pain "down the back," and said now and then in a stammering way, "Oh, so cold, so cold!" It was impossible to count her pulse or hear her heart-sounds. Respirations were 36. As each breath was drawn the shivering became more violent up to the end of inspiration; the inspiration was noisy, and ended prematurely with a jerky closure of the vocal cords; during each expiration there was a slight but distinct quieting down of the convulsions. The temperature, taken carefully in the axilla, was 98·4°. She was as conscious as she ever is, and, though in a slow stammering way, answered one's questions pretty well. The rigor went on without intermission, the spasmodic muscular contractions which constituted the shivering becoming gradually more severe, and the skin colder and of a blue tint. Twenty-five minutes from the onset of the rigor the patient became unconscious, and a violent epileptic "fit" occurred, the tonic stage of which was absent; a comatose condition followed lasting for twenty minutes, after which the patient resumed her usual state, though of course she was much prostrated. The temperature throughout was at the normal.

Remarks.—Amongst the almost innumerable phenomena which usher in epileptic seizures, an aura such as this, presenting all the subjective and objective symptoms (excepting pyrexia) of an ordinary rigor would seem to be rare. In this case the stage of "contraction of the facial," which usually precedes that of the "cerebral vessels," seems to have been exaggerated; the spasm spread over the whole cutaneous vascular system, and hence the subjective "cold" and the complete rigor. It was interesting to note that the tonic stage of the fit was absent; probably the muscles were too much exhausted by the twenty-five minutes' duration of the rigor to develop any strong tonic spasm. The "fit," however, was distinctly separable from the rigor, the patient suddenly becoming unconscious, and the spasms of the rigor developing into clonic convulsions of a very severe type. The case is of some interest, too, when viewed in the light of a further testimony to the close pathological analogy between the two phenomena ordinarily distinguished by the names "rigor" and "convulsion."

WESTMINSTER HOSPITAL.

SMALL-CELLED SARCOMA OF THE FEMUR; AMPUTATION AT THE HIP-JOINT; RECOVERY.

(Under the care of Mr. G. COWELL.)

THE following case would appear to be one in which a sarcoma of the femur developed after, and apparently as the result of, a slight injury to the thigh, forming an example of what has been described as "acute traumatic malignancy." In THE LANCET for 1885, vol. ii., p. 1035, there is an excellent paper by Mr. Pearce Gould on "Sarcoma of Bone rapidly following Injury," and we would refer our readers to that for information on the subject, which is ably discussed. It would hardly be possible to get a better result than was obtained in this case by the employment of Davy's lever, the amount of blood lost during the operation being excessively small. The author of the paper to which we have referred prefers a modification of Furneaux Jordau's operation in such cases, performing a circular amputation of the thigh, securing the vessels, and then completing the operation by an incision along the outer side, through which the bone is disarticulated.

The following notes are furnished by Mr. Walter Arthur, surgical registrar.

H. H——, aged ten years, a schoolboy, was admitted on Oct. 21st, 1885, into Northumberland ward. The patient was a well-nourished boy, but of strumous appearance. He had had no previous illness. Both his grandparents are living and healthy; his father, who is a painter, is suffering

Digitized by Google

from lead palsy; his mother is in good health. The boy has two brothers and one sister living, all of whom are strong and well; two brothers died young, but the cause of their death cannot be ascertained. On May 25th last the patient was sliding down some steps, when he fell down the last two, hurting the outer side of his left leg, about the middle, the skin being abraded. The following week a swelling was noticed at the lower and inner part of the left thigh. It became hot and painful, and rapidly increased in size.

On admission, a large tumour was found occupying the lower third of the inner side of the left thigh. It was rounded, smooth, and semi-elastic, and the skin covering it was tense. It was quite immovable, and seemed firmly attached to the bone, and was hot and at times painful. The knee-joint was not involved, and contained no effusion. There was no enlargement of the lymphatic glands.

On October 27th the patient was put under the influence of chloroform, and amputation at the hip-joint performed. The vessels were ligatured, and the well-rounded anterior and posterior flaps were brought together with silver wire sutures. The operation was strictly antiseptic. The external iliac artery was controlled by Mr. Richard Davy with his rectal lever, the patient losing only three ounces of blood.

Oct 28th.—The patient passed a fairly good night after the operation. There is some pain in the stump and slight headache. Pulse 110; temperature 101°.

29th.—The stump was dressed, on account of some signs of the discharge having come through. The wound looked quite healthy. The patient's general condition was good. The temperature ranged between 98·4° and 102°.

Nov. 4th.—The wound is healthy and healing, and there is little discharge. The drainage-tube was removed on the 2nd. The patient's appetite is good, and he is otherwise progressing favourably. Since the last note the temperature has ranged between 98·4° and 101·4°.

7th.—The boy is improving and the wound healing; there is rather more discharge to-day, but it is quite sweet. The temperature is normal.

16th.—The wound has nearly healed, and the patient is convalescent.

Mr. Cowell described the case as one of rapidly-growing sarcoma of the femur after injury, and called attention to the frequency with which this disease occurs in children from apparently trivial injuries. Removal of the whole of the implicated bone was necessary for the eradication of the disease. On subsequently examining the growth, it was found to be firmly attached to the bone and encapsuled by the periosteum. Nodules of the disease were found in the medulla of the bone through the whole of the diaphysis; the epiphyses were not involved. The microscopic examination showed a small-celled sarcoma.

ROYAL ALBERT EDWARD INFIRMARY, WIGAN.

TRAUMATIC RUPTURE OF URETHRA; PERINEAL SECTION; COMPLETE RECOVERY; REMARKS.

(Under the care of Mr. W. C. BARNISH.)

FOR the following notes we are indebted to Mr. John Buchanan, house-surgeon.

Patrick C—— was admitted into this hospital at 7 A.M. on Sunday morning, Sept. 20th, 1885. At 7 P.M. the previous evening, while standing with his legs extended between two halves of a counter in a public-house, he was caught on the foot by one of his comrades causing him to come down straddle on the counter door. He had much pain immediately after the accident; no blood came by the urethra, but an hour afterwards he found himself unable to pass urine. He returned home and went to bed, and in a few hours became so ill, with inability to micturate and intense pain, that he called in one of the medical men of the town at 4 A.M. Some blood had come from the urethra by this time. Unsuccessful attempts were made to pass a catheter, and blood poured freely from the urethra at each trial. Aspiration above the pubes was performed, with consequent relief, and his removal to hospital ordered.

On admission, attempts were again made to pass a catheter, but as profuse hæmorrhage was easily set up they were not persisted in. The point could be felt grating in the tissues. A hot bath was of no avail. A hypodermic injection of morphia was administered, and the man lay quiet and comfortable during the day. Towards evening the bladder became distended, and at 7 P.M. dulness was within an inch of the umbilicus. Temperature 98·8°. Man feeling very ill. An enema of soap and turpentine was ordered, which acted copiously immediately, but gave no relief. Considerable hæmorrhage continuing from urethra. At 9 P.M. the patient was put on the operating table, chloroform administered, and perineal section performed by Mr. Barnish. A grooved staff was passed down the urethra to the seat of obstruction, and the point could be felt in the perineum just behind the scrotum, with the left forefinger in the rectum, Mr. Barnish plunged his knife in the middle line immediately in front of it, and cut towards the centre of the perineum. With the finger in the wound the point of the staff could be felt, covered with tissue, and with a little dissection it was cleared. With some difficulty the opening of the urethra towards the bladder was found, and a celluloid catheter passed in. The staff was now removed, and a gum-elastic catheter with boule point passed down the urethra from the meatus and out at the wound. It was then curved on itself and passed in from the wound to the bladder, the celluloid catheter being first removed. The catheter was now tied in position, the wound plugged with oiled lint, and the patient removed to a separate ward.

Sept. 21st.—9 A.M.: Patient comfortable; slept most of the night without any narcotic. Only a little bleeding from the wound; plug removed. Urine passing freely by catheter. No sickness. Temperature 101·2°. A pad was applied to the wound.

22nd.—Spent a good night; no pain; no hæmorrhage. Communication through catheter free. On introducing the finger gently into the wound the catheter can be felt exposed for about an inch.

23rd.—A drop of pus at the wound and at the meatus. Bowels rather relaxed.—7 P.M.: Patient very ill; tube blocked. Temperature 102·8°, and a blush over the scrotum. A large water dressing applied.

24th.—Blush gone; patient feels well.

28th.—Tube blocked; patient very ill in a short time. Cleared, and the patient felt well in a few hours. Urine very gritty; acid mixture injected into bladder. Much pus per urethram. Tube again blocked and cleared; urine much the same.

30th.—Urine much clearer than two days ago.

Oct. 2nd.—Up to this time only a little urine had come by the wound at intervals, and at 10 A.M. to-day the catheter was removed. The removal caused considerable pain, as the bulbous point was thickly coated with phosphates. An ordinary metal catheter (No. 10) was now passed regularly three times in the twenty-four hours for a few days.

6th.—Passed urine himself, and in a good stream.

8th.—A double-barrelled catheter (No. 11) was now passed twice daily, and the bladder washed out with an acid solution. From this time the patient made an uninterrupted recovery.

19th to 29th.—No urine came by the wound. He passes a good stream. Catheter passed daily. Patient regarded as convalescent; sits up most of day; greatly weakened by the process, and has lost much flesh.

30th.—Patient discharged.

Nov. 5th.—From Oct. 29th till to-day a little urine has come each day by the wound, but none since, and patient has resumed work.

20th.—Attends twice a week to have a No. 12 catheter passed, which is accomplished without the slightest difficulty; he is now to attend once a week.

Dec. 14th.—Wound remains perfectly closed, and patient feels very much the same as before the accident.

Remarks by Mr. BARNISH.—This is another of those cases which show the necessity of decided measures being taken early in instances of this serious accident—traumatic rupture of the urethra; and the completeness of the cure in the comparatively short space of time in this case shows the confidence with which perineal section may be adopted. There is the question whether, when the urethra is opened from the perineum, it is better to pass a catheter in from the wound into the bladder and let the urine drain by the perineum, or to pass it down from the meatus, as was done in this case. In this case the latter method acted so well that we may safely adopt it again in a similar one. The ease with which the soft flexible catheter *à boule* (Weiss's best) was borne was very noticeable, compared to what is the general experi-

Digitized by Google

ence of keeping in a metal instrument. The method secures the patency of both ends of the urethra towards the wound, and the opening of the prostatic portion of the urethra into the wound is probably much more easily found with the point of a flexible instrument curved upon itself than with the point of a solid instrument which has passed through the penile portion. The necessity of keeping the catheter from becoming blocked by passing a stilette every day, or every second day, cannot be too much insisted on, as was seen by the rapidity with which the man became seriously ill when this occurred, and that this was the sole cause was evident from the equal rapidity with which he was restored to comfort as soon as it was cleared. In the twelve days in which this catheter was retained it had not corroded or altered in structure so as to obstruct its patency (it became blocked with the gritty matter from the bladder), or to cause any fear of danger from the end dropping off into the bladder. In another case, however, I should not be disposed to leave it so long, as the deposit of phosphates on the boule caused considerable pain on extraction, probably even adding somewhat to the laceration of the urethra.

ROYAL UNITED HOSPITAL, BATH.

A CASE OF EXCISION OF THE RECTUM FOR SCIRRHOUS CANCER; RECOVERY; REMARKS.

(Under the care of Mr. H. W. FREEMAN.)

THE notes of this man's history were supplied by Mr. G. Helps, house-surgeon.

J. H——, aged forty-seven, a warehouseman, applied at the hospital on Aug. 26th, 1885, to get relief from piles. He stated that some small piles externally had troubled him a little for three years, but that he was in his usual good health, passing daily solid full-sized motions until three months since, when he began to get uneasy "about his seat," passed slimy stools with some blood, his bladder also became irritable, and he lost his appetite and became visibly thinner. No family history of malignant disease could be made out. He was one of five children, all healthy; and both parents were alive and well. Had always lived a steady life, and had never had syphilis.

On digital examination of the rectum, a hard, nodular, ulcerating growth was felt, commencing half an inch above, but *not* involving the sphincter, and extending for two inches and three-quarters vertically upwards along the long axis of the gut. It seemed to encircle the bowel annularly, except for an inch anteriorly, contiguous to the prostate, and this was smooth and quite free of disease; the bulk of the growth was felt to be placed chiefly posteriorly, and on the right lateral aspect, where it was very thickened and markedly adherent to the deeper structures. The growth, however, moved freely enough elsewhere, and the tip of the index-finger could be carried well beyond the upper margin. The case was thought to be an excellent one for excision, and the patient declared for the operation. Accordingly, on Sept. 2nd he was placed under ether, and a No. 10 silver catheter passed into the bladder and held there. Mr. Freeman then passed a curved, sharp-pointed bistoury, guided by the finger, well above the upper margin of the growth in the posterior wall of the bowel, plunged it backwards, bringing out the point at the tip of the coccyx in the middle line, thus making the triangular incision of Denonvilliers. Then with a small pair of Gardiner's straight, probe-pointed scissors he cut through the marginal union of skin and mucous membrane all round the sphincter, except for an inch in front, and with the finger and scissors the bowel was gradually separated from the levator ani and deep fascia, from behind forwards, until that portion of the bowel was reached adjacent to the prostate, where about one inch was found smooth and free. This was not separated, but was cut out and left *in situ*. A strong clamp was placed on the highest part of the growth when well drawn down and cut through with scissors. Portions of remaining growth were well searched for, and all suspicious particles removed. The peritoneum was not seen. All vessels were tied or twisted, but the hæmorrhage was of a trifling character throughout. Hot water was injected, and carbolised sponges soaked in Friar's balsam plugged the wound completely. An eight-inch gum-elastic vaginal tube was passed between these sponges into the cut orifice of the bowel above and retained. No attempt to bring the bowel and edges of the wound together was made, and a T-bandage was applied to make secure.

The patient was considerably collapsed for three or four hours after the operation; but he rallied during the evening and took brandy-and-water, had one-sixth of a grain of morphia injected hypodermically, and passed a fair night. The sponges were all removed on the following morning, the tube retained, and the huge ischio-rectal cavity was washed out with Condy's fluid lotion, repeated every four hours, with a couple of ounces of eucalyptus oil (1 in 10) injected subsequently to keep sweet. His bladder was troublesome for four or five days, but it subsided without treatment and gave no trouble afterwards. He passed enormous quantities of flatus through the tube, with great relief, and the first fæcal evacuation took place on the fourth day. The seventh day after the operation his temperature, which had never been above 101° at night, fell to normal, and, complaining of sweating, he was given Schacht's cinchona for his apparent exhaustion and cascara sagrada to keep his stools soft. He seemed to be doing well in every way, the wound suppurating freely and healthily, until the twenty-first day after the operation, when he felt chilly, his temperature rose to 104·6°, followed by a rigor, and the following morning a blush was seen about the margin of the wound and cellulitis spreading upwards into the ischio-rectal cavity. This condition gave rise to considerable anxiety, but the washings of the wound were more frequently repeated, large doses of quinine and perchloride of iron being given periodically, and in ten days the temperature became again normal, the healthy discharge supervened, and he progressed towards recovery without any further drawbacks. The tube was withdrawn on the eighteenth day after the operation, and by the aid of a Trouvé's electric light it was interesting to see, from time to time, how the healthy margin of intestine seemed to be growing downwards towards the external orifice, which contracted rapidly. He was kept in hospital for observation until Dec. 19th, when he desired to be discharged, looked well and putting on flesh. The cicatrised external orifice at this time was cartilaginous, gristly to the touch, and admitted the index-finger, and he had some considerable control over his fæces. He came again in three weeks after his discharge, and his condition was satisfactory. The microscope showed undoubted scirrhus.

Remarks by Mr. FREEMAN.—The case on careful examination was thought to be one specially adapted for excision, because the upper margin of the growth could be easily reached with the finger. It was readily movable; the adhesions were partial, and chiefly to the levator ani of the right side. The growth also was in its infancy, and but little constitutional effect was apparent. The key of the operation seemed to hinge on the free posterior incision as practised by Denonvilliers, as we get immediate control over the bowel and but little hæmorrhage, and this man did not lose more than a couple of ounces of blood from beginning to end. The separation of the gut from the surrounding tissues seemed easy enough in this early stage, and although at the time it seemed right to leave the healthy portion of bowel anteriorly, I regret it now, notwithstanding its freedom from disease. To do excision at all, I believe it should be done completely, and the whole calibre of the bowel removed, and to this course I see Volkmann assents. The touch does not seem to me sufficient to guarantee the absolute immunity of a part, and time will show here how far the remaining portion of bowel should or should not have been removed. The disease did not reach within a full half-inch of the sphincter, and extended upwards two inches and three-quarters, its longest diameter being annular, as usually found. It is interesting to speculate how far embryonic development will explain the locality of malignant disease of the rectum. The tucking in of the anal invagination of the epiblast for about two inches to two inches and three-quarters extends upwards to meet the hypoblastic part of the hind gut, and goes to form the so-called "proctodæum," and here a faint white line can be sometimes discerned, and here the disease is usually found to begin spreading out mostly in a circle. Much the same thing is found in cancer of the throat; the stricture is usually at the white line there—the so-called "stomodæum." Free granulations probably absorb, and the cellulitis that ensued was the result of contagion conveyed by the hands of the nurse who washed out the parts, as she was known to have daily dressed a phlegmonous case of erysipelas in another

Digitized by Google

ward. The patient derived great comfort from the tube in the rectum, as it conveyed off collected flatus, and it was useful to wash out high up the chasm. His stools were kept soft with cascara sagrada and glycerine. The purulent discharge was enormous, but after the septicæmic intoxication had passed away he took his food and stimulants well, and he did not again look behind him. He has been desired to come up for inspection from time to time so as to keep a good look out on the cartilaginous contracted anus.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Trabeculated Skull in Infants.—Diffused Symmetrical Pulmonary Cirrhosis.—Lympho-sarcoma of Stomach.—Cylindroma of Palate.—Ante-mortem Digestion (?) of Stomach.—Congenital Adeno-sarcoma of Kidney.

AN ordinary meeting of this Society was held on Tuesday last, Dr. J. S. Bristowe, F.R.S., President, in the chair.

Dr. GOODHART showed a Trabeculated Skull from an infant aged six months, who had also a spina bifida. It died as the result of injection of Morton's fluid. On the inner aspect the calvaria presented a number of ridges or arches of bone with membranous opercula or thin plates of bone between. The relation of this condition to cranio-tabes was mooted. There was no evidence of congenital syphilis or rickets. It was probably better to regard it as a malformation, another condition of skull to that of cranio-tabes.—Dr. HALE WHITE gave an account of a trabeculated skull in an infant. The patient, a child three months old, was admitted into Guy's Hospital for a large congenital tumour projecting upwards from the anterior half of the head. It was tapped and cerebro-spinal fluid drawn off, but the child gradually sank and died. At the necropsy the following condition was observed:—There was a transverse depression across the skull from ear to ear; the frontal bones were widely separated; their opposite borders were indented; the interval was filled up by membrane. The other bones of the skull were so firmly united that in some places the sutures could hardly be made out. The two parietal bones were close together. The bones of the base were normal, but all the bones of the vertex were remarkably thin, being about the thickness of egg-shell. The parietal and that part of the occipital in front of the foramen magnum for the most part retained their membranous condition, but going across the membrane in all directions were trabeculæ of osseous tissue; the average width of these was one-sixth of an inch, and they formed sharp prominent ridges on the interior of the skull. The smallest trabeculæ were the merest sprinkling of osseous substance in the membrane, which was thus cut up into a number of areas, some rounded, some polygonal, and varying in size from a mere point to a threepenny-piece. The dura mater followed these ridges accurately. Seen from the exterior, the transparent membranous areæ bounded by trabeculæ were very evident, but there were no ridges. On the petrous portion of the temporal bone the superior and posterior semicircular canals were most evident. There was no flattening of the convolutions of the brain, the ventricles were not dilated, and it was impossible to say whence the fluid which was drawn off came, and also to say what was the cause of this peculiar condition of skull.—Mr. SHATTOCK had seen similar specimens. In one instance there was spina bifida, followed by hydrocephalus. He explained the appearance as a result of atrophy resulting from internal pressure; the bone between the convolutions being left.—Dr. DYCE DUCKWORTH related a case of chronic hydrocephalus which presented a typical example of cranio-tabes.—Mr. R. W. PARKER said that Bednär had described congenital membranous holes in the skull. He had seen cranio-tabetic conditions in cases of hydrocephalus. With the original opinion of Elsässer he agreed, that rickets in suckling infants gave rise to cranio-tabes.—Dr. J. S. BRISTOWE believed that the fluid must have been in the ventricles.—Dr. GOODHART, in reply, said in his case there was no hydrocephalus. In hydrocephalus he had seen something like it, but not the same condition. It appeared to him as though the bone were forming in the membrane and making its way inwards.—Dr. HALE WHITE could not admit that internal pressure would give rise to this special condition.

Dr. PERCY KIDD read notes of a case of Diffused Symmetrical Cirrhosis of Lungs, which occurred in a woman aged thirty-seven, in whom expectoration, short breath, cough, anasarca, pains in the chest and back, loss of appetite, enlargement of the right side of the heart, and dulness about the right apex and both sides behind, with albuminuria and scanty urine, were the chief clinical features. The heart was hypertrophied, and weighed seventeen ounces and a half. On section of the lungs, dry, deep-red, branching fibroid strands, perfectly symmetrical, pervaded all parts; irregular nodular patches were also to be seen, probably the transverse sections of the branching bands; there was no special thickening of the interlobar septa. In the left upper lobe a mortary mass was discovered, and elsewhere a few caseous nodules. The mediastinal glands were large, tough, and pigmented. In some places the microscope revealed thickening of the alveolar walls. The branching bands appeared to be of peribronchial situation, and microscopically showed all degrees between a cellular and fibrous structure. The perivascular changes were, however, purely fibrous. There were many hæmorrhages that probably resulted from the wide thin-walled capillary vessels. The kidneys and spleen were indurated. In places there was some intra-alveolar fibrosis, and but a slight degree of pleuritic thickening. No tubercle bacilli were to be discovered anywhere. The new growth of fibrous tissue was of bronchial or peribronchial origin, and, pathologically, might be described with some German authors as peribronchitis fibrosa. The caseous nodules were possibly gummatous.—Dr. GOODHART considered that the presence of general arterial sclerosis lent support to the view that the case was one of syphilitic phthisis, of which disease he had seen several examples.—Dr. GREEN regarded the specimen as one of great rarity, and did not look upon it as syphilitic.—Dr. PERCY KIDD thought the condition might possibly be syphilitic.

Dr. HADDEN showed a specimen of Lympho-sarcoma of the Stomach which came from a woman aged fifty-three, in whom weakness, pallor, loss of flesh, and pleuro-pneumonia of the left lower lobe were the chief clinical features. During life also a tumour in the hypogastrium, which turned out to be a uterine fibroid with an elongated pedicle, was detected. There was some degree of leucocythæmia. The specimen shown was a globular tumour on the anterior wall of the stomach projecting forwards midway between the orifices and near the lesser curvature; on the inner aspect of the organ was to be seen a triangular ulcer that led an inch and a half into the tumour; a second ulcer, smaller, was situate on the left of the first. Fatty degeneration of the heart also existed. Microscopically the tumour exhibited small, rounded, nucleated cells lying in a reticular structure having a papillary or alveolar arrangement. Necrosis had probably produced the ulceration and the prolongation inwards. Allusion was made to a specimen of malignant lymphoma of the mesentery shown by Mr. Silcock last session.

Sir WILLIAM MAC CORMAC exhibited a Tumour of the Palate taken from a woman, aged thirty, in whom the voice had become thick, and difficulty in swallowing existed. About two months before admission a swelling was noticed by the patient in the mouth. The tumour, nearly the size and shape of a Tangerine orange, occupied the left half of the palate, and reached nearly to the teeth in front; it had a firm elastic consistence, and was very vascular on the surface. The lymphatic glands at the angle of the jaw were enlarged. A preliminary tracheotomy was done to prevent suffocation from hæmorrhage, which was very free, but stopped by pressure and thermo-cautery. The cheek was incised before the tumour was enucleated. The hole in the hard palate was closed by an obturator. The microscope showed a hyaline connective tissue, traversed by groups of cells having a branching form; Mr. Shattock pronounced it to be a cylindroma of the palate. Reference was made to specimens exhibited by Mr. Treves, and also to others that had occurred in the practice of Verneuil and other continental surgeons.—Mr. A. A. BOWLBY agreed as to the tumour being a genuine cylindroma. It reminded him of a specimen shown by Mr. Butlin from the popliteal space; this was also encapsuled, but still very malignant, and led to amputation of the thigh. The clinical history of cylindroma was not a benignant one; the tumour was, indeed, but one form of round-celled sarcoma.—Mr. BUTLIN agreed with the remarks of the previous speaker.—Mr. F. T. PAUL had seen similar

Digitized by Google

tumours in the tonsil, cheek, and lip, which he regarded as of adeno-myxomatous nature, like the tumours of the parotid gland.—Dr. F. SEMON said that, judged by the number of cases that had been recorded, he had come to the conclusion that both benign and malignant tumours of the palate were very rare.—Mr. SHATTOCK could not agree with Mr. Paul that the cylindroma of the palate was like the parotid tumours.—Mr. ROGER WILLIAMS had seen two similar tumours in the upper lip.

Dr. HANDFORD exhibited a specimen of Ante-mortem Digestion of Stomach. The patient was a man aged twenty-three, who had had an attack of hæmatemesis and melæna two years before his final illness, which began last year on July 20th, when he was walking by the side of the Trent. The man felt dizzy, had pain in the abdomen, and fell down. On admission to the Nottingham Infirmary he was pale, and had severe pain, which was relieved by pressure in the epigastrium. The abdomen was flat; there was difficulty in swallowing; a slough was noticed on the margin of the soft palate. He was fed by milk and ice, and given a hypodermic injection of morphia. His condition was unaltered from July 21st to 23rd. On the 24th he vomited one pint of blood. He was moribund on the 27th, and died on the 28th. The necropsy was made five hours after death. A blood-clot covered the left lobe of the liver, and weighed 1 lb. 13½ oz. There was a cavity, with friable, rough, irregular walls, occupying the region of the stomach; the liver projected into the cavity. There were no signs of general peritonitis, but the cavity was shut off by adhesions. A softened discoloured patch was found in the diaphragm, and another in the omentum. Poisoning was suspected, and Taylor on Forensic Medicine referred to cases of corrosive poisoning that lasted a few days. There were fermentative changes in the blood-clot; he had submitted the specimen to Mr. V. Horsley, who said there was no trace of thrombosis of the gastric vessels.—Dr. BRISTOWE asked for information as to the adhesions; was the hæmorrhage into the stomach? In reply it was stated that the adhesions were recent, but the stomach had been so much destroyed that it was difficult to say where the hæmorrhage had occurred, the only recognisable parts of the stomach being the pyloric and cardiac orifices. The kidneys were healthy.—Dr. F. PAYNE asked whether an analysis were made as to poisoning. If the case were one of ante-mortem digestion it would be unique in medical literature.—Dr. HALE WHITE pointed out that the cavity described corresponded exactly with the lesser cavity of the peritoneum, and considered that post-mortem digestion might account for some of the appearances.—Dr. HANDFORD was inclined to regard the case as one of corrosive poisoning in the first instance, but believed that considerable ante-mortem digestion of the stomach had also occurred.

Mr. F. T. PAUL (Liverpool) showed specimens and drawings of Congenital Adeno-sarcoma of Kidney taken from a girl aged two years. The clinical history had already been published in the *Liverpool Medico-Chirurgical Journal* of 1885. The tumours were situate between the pelvic membrane and the substance of the kidneys. Microscopically broad trabeculæ of rounded cells were to be seen, and also tubes with considerable lumen; the complex nature of the tumour, having round cells, spindle cells, white fibrous tissue and elastic tissue, with young striated muscular fibres, was referred to. There was no doubt that much of the tumour was composed of newly formed renal tissue. The specimen was congenital not only in origin but also in growth. He also read a brief paper on Calcification of Arteries, alluding only to that of the muscular coat of the smaller arteries as met with in senility. The process was associated with a genuine process of ossification, although it commenced as a calcification. After the calcification the hard plates became fractured in various directions. This led to irritation and the deposition of inflammatory products. In the calcareous plates a fibrous structure, the remains of the muscular fibres, and also sometimes laminated spherical deposits, could be discovered. The plastic inflammatory products developed into bone. The changes were well seen in the posterior tibial artery; here the fractures in the calcareous plates were mended with patches of bone, even sometimes having the appearance of Haversian systems. The change could be seen in a thrombus also. The order of change was calcification, followed by irritation and exudation of lymph, while ossification took place.

The following card specimens were exhibited:—Dr. Payne (for Dr. Jacob, of Leeds): Tumour of Finger (referred to Morbid Growths Committee). Dr. Hadden: Single Cyst of Liver. Dr. Handford: (1) Right-sided Ulcerative Endocarditis; (2) Acute Intestinal Obstruction, due to a band; (3) Thrombosis of Left Posterior Cerebral Artery; (4) (for Mr. E. Powell) Congenital (?) Atrophy of Right Kidney. Dr. Pasteur: Aortic Aneurysm with Mitral Stenosis. Mr. E. H. Fenwick: Post-trigonal Pouch of Bladder, containing Stone, Kidneys Hydronephrotic. Mr. Shattock: Lumbo-sacral Meningo-myelocele cured by Morton's Treatment.

CLINICAL SOCIETY OF LONDON.

Hernia Cerebri treated by Silver Plate closing the Opening in Skull.—Nervous Sequelæ of Small-pox, especially as affecting the Speech.—Baruria in a Woman.—Phosphorus Necrosis of Lower Jaw.

AN ordinary meeting of this Society was held on the 12th inst., Mr. T. Bryant, F.R.C.S., President in the chair.

Dr. MACLAREN read an account of a case of Hernia Cerebri successfully treated by closing the Opening in the Skull with a Silver Plate. A man, aged twenty-six, was admitted to the Cumberland Infirmary on March 25th, 1885, with a compound fracture of the skull inflicted three days before. For six days after his admission his condition grew progressively worse. He became deeply comatose, passed motions involuntarily, and had frequent convulsive attacks. The scalp wound was then enlarged, and all fragments of bone removed; they were ten in number, and some deep in the brain substance. The aperture left in the skull was three inches long, and varied in breadth from one inch above to half an inch below; it was three-quarters of an inch in front of, and parallel to, the left temporal ridge, and its lower end was at the supra-orbital ridge. Some brain which had protruded was removed and some diffluent brain gently syringed away. While being put under chloroform it was noticed that the right side was paralysed. An unsuccessful attempt was made to make the wound aseptic. From this time his condition improved; he gradually became less comatose, convulsions ceased, and in about a fortnight he understood what was said to him, though he did not speak. By this time hernia cerebri had again occurred, and Dr. Maclaren removed it on April 14th placing a silver plate (a rolled out florin) inside the skull, so as to block the opening. On May 3rd the hernia cerebri again existed, owing to the plate slipping to one side within the skull. The protrusion was cut off, and this time the plate so secured with wire that it could not be thrust to one side. The scalp was liberated by two incisions parallel to the wound and sutured over the plate. The plate was left in for two months, no protrusion occurring, when it was removed, and the wound soon healed. He was discharged from the hospital on Sept. 5th, when there was slight dragging of the right leg, absolute paralysis of the right arm, and slight want of expression on the right side of the face. He was sometimes at a loss for a word, and much given to repeat the same expressions. During the latter part of his stay in the hospital he had two fits, and he has had several since mostly at night, and always with an aura. The paper pointed out the very small amount of local irritation caused by the plate, which did not exercise any pressure on the brain, but merely replaced the normal covering. The result was a substantial reason for trying it again in a similar condition.—Mr. BRYANT congratulated Dr. Maclaren on the success of his case; the treatment was novel, but he doubted whether it would replace persistent external pressure—say, with thick sheet-lead,—by which method he (Mr. Bryant) had obtained considerable success; he deprecated removal of cerebral hernial substance. He asked why external portions of the hernia were sliced off.—Mr. GOLDING BIRD related three cases of hernia cerebri. Tannic acid was found to be a useful application in the first case, which recovered completely. In the second case tannic acid was employed, but extensive sloughing and fatal cerebritis ensued. In a third case simple antiseptic dressings were used, with ultimate success. He ventured to think that external pressure would prove equally satisfactory with internal pressure.—Mr. A. PEARCE GOULD spoke of a case of hernia cerebri the size of a Barcelona nut; external pressure by means of a pad of lint failed to repress the growth; there were no symptoms till convulsions set in, which being repeated, Mr. Gould shaved the hernia off, and opened and drained an abscess;

Digitized by Google

some paralysis occurred after this, but passed away, and the boy recovered completely. He considered that the tendency to the development of cerebral hernia depended on the intracranial condition, such as inflammation.—Dr. MACLAREN, in reply, said that external pressure was tried in every form. Lawrence had pointed out that in fungus testis there was a mixture of granulation tissue and the proper tissue of the organ; so it was in hernia cerebri.

Drs. WHIPHAM and A. T. MYERS read a paper on some Chronic Nervous Sequelæ of Small-pox, especially as affecting the speech, and narrated the particulars of two cases. They had been unable to find any reference among English writers, although doubtless such cases occasionally occur in this country, seeing that several instances are on record in Germany and in France. The patients were married women, aged forty-five and forty-two respectively; one had small-pox in 1879, the other in 1881, and both recovered incompletely with some paralytic and ataxic symptoms, the chief peculiarity being an affection of the speech, in which the syllables were scanned or "squeezed out." In the first case the patient had enjoyed excellent health until she fell sick of small-pox, three weeks after confinement. The disease was of the confluent variety. She was delirious for twelve days, and on recovering her senses it was found that she was unable to make herself understood for the next few days. There was much muscular weakness in her hands and legs. Her temper became very irritable. Her tongue was protruded to the right at first, with the tip pointing downwards, and as protrusion was completed, it gradually assumed the normal position, and this symptom lasted for three years. The right azygos uvulæ acted more powerfully than the left. Her power of writing left her in the earlier stages of the disease, but was subsequently recovered to a great extent; she could not button her clothes, and if she held a cup in her hand she was liable to drop it; the left hand was more affected; the grasp of both was feeble. Sensation was perfect, and her intelligence when under observation at St. George's Hospital was remarkably acute. The legs were affected at first, and her gait was extremely awkward and unsteady. With the exception of the affection of the speech, she recovered from all these symptoms. She first came under observation in Jan. 1880, and on Nov. 15th, 1885, the peculiarities of speech remained—viz., her inability to pronounce correctly such words as "Clara," which became "Nai-dee"; "Richard," which was pronounced "Nit-erd"; each syllable was forcibly jerked or "squeezed" out. When she attempted conversation it was almost impossible to understand her. The second case was that of a woman aged forty-two, who had enjoyed good health until July, 1881, when she caught small-pox. The disease was modified by vaccination, but for the first few days she was in a state bordering on mania, and unable to articulate. She bit and tore the bedclothes with her teeth, and grasped objects firmly with her hands, although she had nearly lost the power of moving her upper and lower extremities. Stools were passed voluntarily. Her pupils were unequal. In this state she remained for a week. She then partially recovered her senses and her power of articulation. Her speech very closely resembled that of the former case, being slow, nasal, and monotonous; each syllable was jerked out in a semi-explosive fashion, but she did not, as in the former case, experience difficulty with special letters or words. She was liable to outbreaks of temper, and her gait showed some incoördination, though there were no symptoms of locomotor ataxy or disseminated sclerosis; the deep reflexes in the legs and arms were slightly in excess. She could not perform the movement of the shake on the piano, nor could she plait her hair; she could not nurse her child lest she should drop it. During the four years she was under observation she regained control over her limbs, and her speech at the last examination (Nov. 15th, 1885) showed slight improvement. Inquiry at some of the chief small-pox hospitals did not furnish any similar instances, except at Deptford, where Mr. Struthers had met with two cases in which speech became unintelligible, one of which recovered in three weeks and the other died. It was remarked by the authors of this paper that the clinical picture in these was not that of disseminated sclerosis. There was sudden onset, but no increase of tremor on motion, and no nystagmus, and the "squeezing out" of the syllables was different from the ordinary form of speech in disseminated sclerosis, and what was more important, the prognosis was better. It was suggested in explanation of the symptoms in these cases that minute scattered hæmorrhages, chiefly cerebral, had occurred, and that such lesions might be more common in small-pox than in other fevers. This hypothesis appeared probable from the fact that out of eight closely analogous cases tabulated by the authors, this peculiar scanned speech had been a sequela in six cases in which the patients had suffered from small-pox. Since this communication was sent into the Society, Professor Jaccoud's clinical lectures ("Leçons de Clin. Med.," 1886) have been published, in which he gives two similar cases from his own practice, one after pneumonia, the other after small-pox.—Dr. HUGHLINGS JACKSON considered the paper one of great interest. He referred to the case of a man aged forty, whom he showed to the Society, in whom the delirium had been very marked and prolonged. There was the same peculiarity of articulation, and also a want of coördination of the hand, especially for finer movements. He believed that similar groups of symptoms occurred without febrile disease. The suggestion that seemed to him best to meet the pathological necessities of the cases was a thrombosis occurring in a minute vessel of the medulla oblongata.—Dr. STEPHEN MACKENZIE had seen several cases of the kind having the same characters in the monosyllabic nasal articulation. Severe malarial poisoning could also give rise to the same phenomena, but there was then generally tremor also. He had related a case in *Brain*, that occurred after variola, of anterior poliomyelitis, and suggested that a similar condition of the motor cells of the medulla might give rise to the same phenomena as those met with in the cases in question; the pathological nature of the lesion might also be thrombosis.—Dr. T. BARLOW spoke of a case in which the articulatory symptoms were not so definitely marked as in the author's cases, but which probably belonged to the same category. The patient was a woman aged twenty-five, who was first seen within a week of leaving the small-pox hospital. There was ataxy of the lower and upper limbs; the articulation was altered, but not in the scanned way, though the enunciation was slow and the voice high pitched. Double optic neuritis and deafness, with mental obtuseness, were other phenomena observed. He had seen the case of a man with paralysis of the serratus magnus occurring after small-pox; but peripheral neuritis might have been the lesion here. Dr. Barlow also related a case of fatal myelitis occurring during measles. It was that of a policeman, healthy and young. About four days after the appearance of the rash paraplegia and retention of urine appeared, and the paralysis ascended, but did not affect the brain; death ensued in three days. There was microscopic evidence of myelitis, and most marked in the anterior cornua. He considered that a distinction would have to be drawn between true sequelæ due to a kind of chronic starvation and nervous phenomena occurring during the exanthematic period. It appeared in the last case as though the measles eruption were coming out in the nervous centres. It would be important to note the exact period of supervention of the nervous phenomena in any future cases.—Dr. SEYMOUR TAYLOR referred to a case of amnesia occurring after small-pox, which he thought resembled in some respects those related by the authors of the paper.

Dr. SAMUEL WEST read notes of a case of Baruria in a woman. The patient, aged thirty-nine, complained after catching cold of pains and aching in her limbs, which became severe enough after a week to keep her in bed. When admitted, these pains continued, but there was swelling of joints. The temperature was 100°, and she perspired freely, but the sweat did not smell sour. The urine had a specific gravity of 1040, and yielded copious crystals of nitrate of urea, with nitric acid. Her appetite had been for some days almost absent, and in the hospital she took but little milk or beef-tea. For two days the condition of the urine was the same, and the percentage of urea 5·1. This percentage gradually fell to normal, and as it did so all the patient's symptoms disappeared. The case was regarded as one of baruria. The account of the cases given by Prout was summarised and compared with the present case, and reference was made to other authors, by some of whom the existence of the affection was questioned, while by others it was not referred to. A somewhat similar case, the result of over-feeding and constipation, was described, in which like symptoms were associated with a high urea percentage, and disappeared when the percentage returned to normal.

Mr. HUTCHINSON read a case of Necrosis of the Lower Jaw from the Medicinal Use of Phosphorus. The patient was a lady aged sixty-five, who was seen by Mr. Hutchinson in November last, when the lower half of the face

Digitized by Google

was enlarged, and several sinuses opened externally; bare discoloured bone was exposed in the mouth along the whole length of the alveolus; discharge profuse and fetid in the extreme. In explanation of the origin of the necrosis, it was elicited from the patient that she had "been taking phosphorus for the last two years," and had "quite renovated her brain" thereby, the truth being that, save for a few intervals, she had during the time named been taking three Kirby's pills per diem, each containing the thirty-third of a grain of phosphorus. The condition of the patient being much reduced, operation was deferred pending improvement in her general health, until the present month, when, after consultation with Sir J. Paget, Mr. Hutchinson removed about four inches of dead bone without having to resort to cutting instruments for its separation, although he feared at first this would be necessary. The patient made an excellent recovery. Mr. Hutchinson remarked that Kirby's phosphorus pills were in very extensive use, but that this was the only case in which, to his knowledge, jaw disease could be traced to their employment. The patient had carious teeth at the time, and inflammation of the jaw had begun in connexion with one of them, and probably about six or nine months after the taking of the pills commenced.—Mr. BRYANT said that he had no doubt that osteitis and necrosis of the jaw could come on without any definite cause being ascertained. The cases simulate in their clinical appearances those which we regard as examples of phosphorus necrosis. He referred to two cases—one died of pneumonia, and the other occurred in a pregnant woman. In reply to Mr. Hutchinson, he said the possibility of phosphorus being operative was negatived by careful inquiry.—Dr. BRISTOWE did not doubt the possibility of the occurrence of necrosis from the internal administration of one-thirtieth of a grain of phosphorus three times a day.—Dr. COUPLAND inquired if there were albuminuria; for in phosphorus poisoning fatty degeneration of the kidney occurred.—Mr. HUTCHINSON said there was certainly no albuminuria whilst the case was under his observation.

Dr. EWART exhibited a modification of the Binaural Stethoscope suited for differential observations.

The following living specimens were shown:—Mr. Victor Horsley: Congenital Tract in the Raphe of the Scrotum. Dr. Hughlings Jackson: Affection of Articulation; a sequel to small-pox. Mr. T. Cooke: (1) Primary Epithelioma of the Tonsil; (2) Cyst on Back of Wrist (Ganglion). Mr. Bernard Roth: (1) A patient with Extreme Lateral Curvature of the Spine after three months' treatment; (2) Sister of above case with Lateral Curvature of Spine in earliest stage.

MEDICAL SOCIETY OF LONDON.

Furneaux Jordan's Amputation.—Excision at Hip-joint.—Mediastinal Tumour.—Anæsthetic Leprosy.—Xanthelasma.—Scleroderma.

A CLINICAL meeting of this Society was held on Monday last, Mr. Brudenell Carter, F.R.C.S., President, in the chair.

Mr. EDMUND OWEN read notes of a case of Amputation at the Hip-joint by Furneaux Jordan's method in a boy aged six. The disease began in May, 1885; an abscess formed in the hip and knee-joints; pyæmic abscesses developed in other parts; in August amputation was performed through the lower third of the thigh, but fresh mischief ensued, and amputation by Furneaux Jordan's method was performed in December last. There was considerable enlargement of the liver, and the urine contained a quarter of albumen. After going away to the seaside the boy returned with a stump that evidently contained a thick core of bone; the albuminuria and hepatic enlargement had considerably diminished. Mr. Shuter's case, reported in the Clinical Society Transactions, was alluded to. In Mr. Owen's case this new bone was synostosed to the acetabulum. Jordan's method greatly diminished the risk of amputation at the hip-joint, and he believed it had given the death blow to the old method of transfixion.—Mr. B. CARTER asked whether there was any increase in the secretion of urea.—Mr. B. JESSETT considered that the diminution in the size of the liver in Mr. Owen's case was a point of great importance. He narrated a case showing the same circumstance.—Mr. R. DAVY also bore testimony to the disappearance of a large liver after surgical interference. In Mr. Shuter's case there was some doubt whether the hard formation in the stump was bone or fibrous tissue. In Mr. Owen's case there could be no doubt of the presence of bone.—Mr. B. CARTER referred to the first case of amputation of the hip-joint, in which the femoral artery was ligatured as a preliminary; the patient followed the country surgeon to the grave fifty years after the operation.—Mr. E. OWEN considered that albuminuria from scrofulous disease and crepitations at the apex of a lung were indications for operation.

Mr. WALTER PYE showed the boy on whom he had three years previously performed excision of the hip-joint for acute destructive arthritis; the result was and is still highly satisfactory, considerable movement being possible between the femur and hip-bone.—Mr. E. OWEN had expressed his desire to Mr. Pye to have the time test; the success, he admitted, was perfect.

Dr. WILLIAMS communicated a case of Mediastinal Tumour, causing unusual compression of the neighbouring organs. The patient, a male aged forty-three, was admitted into the Brompton Hospital in December, 1884, complaining of increasing dyspnœa, slight cough, wasting, but principally of intense pain on deep breathing in the left side of the chest, extending over the left side of the head and down the left arm. The physical signs indicated the presence of a tumour growing from the root of the left lung, and compressing that organ, so as to prevent the entry of air. A fortnight later the pain had increased, the cough had become violent, and the expectoration tinged with blood; there was dysphagia, the left pupil was larger than the right, and the left vocal cord was fixed. As the growth increased, the symptoms of pressure became more marked, dyspnœa became severe and paroxysmal, the dysphagia rendered all swallowing impossible, and the patient was fed by nutritive injections. The cough assumed a metallic character, and the voice became stridulous. The left radial pulse was markedly weaker than the right. A systolic murmur was heard under the right clavicle, and each pulsation of the heart was transmitted with such force to the parietes of the left chest, owing to its contents being solid and practically airless, that the presence of aneurysm was at one time suspected. The obstruction to the vascular system was shown in œdema of the right upper extremity, and the patient died of syncope two months after admission. The post-mortem examination showed the presence of a growth occupying the anterior mediastinum, extending from the apex to the sixth rib anteriorly, and crossing the median line to the extent of two inches. The heart was pushed aside, but had been invaded by the growth, the pericardium containing similar tumours, and the left pulmonary artery and the second and third portions of the aorta being considerably constricted. The tumour had encroached on the left lung, infiltrating and destroying its substance, leaving the lower lobe collapsed. The left bronchus was reduced in calibre and the tumour invaded the root of the right lung, occluding the œsophagus and causing the formation on its anterior wall of an ulcer about the size of a shilling. Microscopic examination showed the growth to be lympho-sarcoma. Dr. Williams drew attention to the gradual evolution of the symptoms of compression from the growing tumour, which appears to have extended at the same time in several directions. It was rare to find a lung so completely solid as to transmit the heart's vibrations so faithfully as to give rise to a suspicion of aneurysm—a suspicion which was, however, at once set at rest by the large extent of dulness.—Dr. DE HAVILLAND HALL considered that the audibility of the heart-sounds over the tumour was rather favourable to the diagnosis of aneurysm. He asked what the position of the vocal cord was in Dr. Williams's case.—Dr. S. WEST agreed that there was difficulty in diagnosing pleural effusion from mediastinal tumour, and *vice versâ*. Experience showed that pulsation was not confined to aneurysm. A distinction was drawn between tumours commencing in the mediastinal glands and those beginning in the tissue around the root of the lung and spreading along the bronchi.—Dr. FINLAY and Dr. ANGEL MONEY considered that the employment of the exploring syringe was most valuable, and ought to be more frequently practised than it was.—The PRESIDENT suggested that the pupil might vary according as there was complete or incomplete paralysis of the muscular fibres.—Dr. WILLIAMS, in reply, believed the left vocal cord was in the cadaveric position.

Dr. RADCLIFFE CROCKER read notes of a case of Anæsthetic Leprosy. The patient was a man aged twenty-two, in whom the disease began in October, 1879, with swelling in

Digitized by Google

the leg and severe shooting pains down the limbs. Exacerbations had occurred from time to time; there were the signs of a pulmonary cavity; patches of anæsthesia were present on the thighs, legs, feet, forearms, and arms. The symptoms simulated ague at their onset. Bacilli from pus of broken-down tubercles were shown. Chaulmoolgra oil and Gurgun oil were used in treatment; the tubercles either get absorbed or ulcerate.

Mr. JAMES STARTIN exhibited a case of extensive Xanthelasma in an adult German. The disease began ten months ago on the backs of the hands; the palms, elbows, and knees were successively affected. He had had jaundice three years ago. A case of diffuse Scleroderma in a girl aged thirteen was also shown: it began in the scalp and spread down the face. A man aged fifty, suffering from Angioma of the Left Cheek, was also exhibited.

OPHTHALMOLOGICAL SOCIETY.

Deposit of Quinine in Cornea.—Biniodide of Mercury Solution.—Report on Sympathetic Ophthalmia.—Cerebral Hæmorrhage and Optic Neuritis.—Glaucoma.—Central Blepharoraphy.

AN ordinary meeting of this Society was held on the 11th inst., Mr. Jonathan Hutchinson, F.R.C.S., President, in the chair. It was announced that at the meeting on May 6th a discussion would take place on the subject of Exophthalmic Goitre.

Mr. LANG showed a case of Deposit of Quinine in both Corneæ, with retention of good vision. The quinine had been given internally; eserine was used locally. The original disease was perforating ulcer of the cornea, and an anterior synechia remained in one eye. The deposit was of a very peculiar nature, and gave a fluorescent appearance on focal illumination.—Mr. J. TWEEDY had employed solutions of quinine locally for more than ten years, the solution being frequently applied, and often for weeks together. He had never seen any deposit in the cornea, though he had watched the effect of quinine very carefully. There was a very great difference between English- and German-made quinine; he always used the former.—Mr. NETTLESHIP said the deposit in the cornea was very peculiar, unlike any deposit he had ever seen.—Mr. MCHARDY had not observed any deposit, though he had frequently employed quinine and eserine.

Mr. EDGAR BROWNE spoke of the possibility of obtaining a solution of biniodide of mercury, to which Mr. Brudenell Carter had drawn attention at the last meeting of the Society. The chemist, acting under Mr. Browne's instruction, had succeeded in obtaining a solution, or rather suspension in minutely subdivided form, of biniodide of mercury by using alcohol at 90° as recommended by M. Panas. Chemical reaction showed that mercury was present in the fluid.

Mr. NETTLESHIP read the report of the committee on Sympathetic Ophthalmitis. It was based on a detailed analysis of about 200 cases of sympathetic ophthalmitis collected by the committee as bearing upon certain points in its nature and treatment. About eighty of these were contributed by members of the Society, to whom a circular had been sent; the rest were from published sources. In respect to excision of the exciting eye, the conclusion arrived at was that whilst its removal, soon after the onset of the sympathetic inflammation, had not been proved to have any marked effect on the progress of the sympathetic disease, it certainly did not increase the severity of it; comparing equal numbers of cases in which the exciting eye was, and was not, removed (soon after the onset of the sympathetic disease), the proportion in which the disease was fatal to sight was much greater in the latter group than in the former; the apparent value of this evidence in favour of early excision, however, was somewhat diminished by evidence of another kind, which tended to show that the excess of recoveries after excision was partly due to the natural mildness of the disease in that group, and the excess of losses when excision was not performed, to its natural severity. In respect to mercury, the conclusion was tentatively arrived at that the drug had probably [illegible] if any, effect; of fifty cases which recovered com[illegible] treated locally in much the same way, [illegible] The effect of [illegible] eye, performed [illegible] unfavourable than is commonly held. In a small series of cases, an iridectomy had been performed on the exciting eye soon after the sympathetic inflammation had set in, and in nearly all with a favourable result to both eyes. The important question was next considered whether sympathetic ophthalmitis could be set up by an eye in which no perforation had ever taken place. After a very careful and thorough examination of cases, the committee had come to the conclusion that the occurrence of the disease without perforation of the exciter, if known at all, was, at any rate, extremely rare. In reply to questions as to the longest and shortest intervals respectively between the lesion of the exciting eye and the onset of sympathetic disease, only about a dozen cases were found in which an interval of more than a year occurred, unbroken by recurrences of inflammation in the exciting eye; and only eighteen in which the interval was a month or less. The longest interval where the exciter had been wounded was twenty years, the shortest nine days. There seemed to be reason for believing that the length of the interval was not without influence on the severity of the sympathetic ophthalmitis; the proportion of cases in which blindness ensued being considerably greater when the disease had set in after a long, than after a short, interval. Consideration was then given to all the cases (about thirty) in which sympathetic ophthalmitis was known to set in after excision of the exciting eye, in five cases in from four to eight weeks after; in all cases the exciting eye had been wounded, and had been left long enough to undergo changes capable of setting up the disease; and the conclusion was drawn that, in these cases, the sympathetic attack was due to the influence of the wounded eye, and not to the operation for its removal. The prognosis in these cases was shown to be much better than in ordinary cases, as more than half recovered entirely. After reference to certain anomalous cases happening many years after excision, and to others where iritis followed the removal of the exciter within a day or two of the injury, the Report concluded with a notice of the cases of so-called uncomplicated sympathetic neuritis. It had been found that these cases of sympathetic neuritis differed much amongst themselves, and probably could not all be ascribed to the same cause, nor be taken as pointing to transmission along the optic nerves; whilst the papillitis, which often occurred early and remained late in ordinary cases of sympathetic ophthalmitis, was far from proving that mode of transmission, since the same papillitis was commonly seen in cases of idiopathic serous iritis, even when only one eye suffered. The Report was illustrated by cases.—The PRESIDENT considered that the report of the committee showed evidence of great judgment as well as great labour, and there could be no doubt that the report would form a most valuable section of the Annual Transactions of the Society. A vote of thanks was unanimously offered to the members of the committee, and the President hoped that the supplementary report alluded to in the report would also be forthcoming.

Dr. BRISTOWE read a paper on a case of Cerebral Hæmorrhage with Double Optic Neuritis. A musician, aged fifty-five, was first seen on Jan. 19th. It appeared that he had suffered from headache for one year, and dimness of sight for six months; but there had been no paralysis, double vision, or fits. At 10.30 P.M. after supper on last Boxing Day loss of consciousness and right hemiplegia suddenly supervened. The patient remained drowsy and stupid, took but little notice of his surroundings, and passed his evacuations into the bed. The arm and leg were absolutely paralysed; the plantar reflex on the right side somewhat diminished. There was no clonus, and the knee-jerks were not exaggerated. Complete hemi-analgesia and anæsthesia were also observed; the special senses could not be investigated. The temperature was 97·4°; the pulse 90 and strong; no albuminuria. For ten days the patient remained the same, then became more drowsy and absolutely speechless. Some stiffness of the right arm came on. The head and eyes were turned to the left, but the patient could move the head and eyes to the right. Mr. Nettleship examined the eyes on Jan. 30th, and found both discs swollen and reddish-grey—a papillo-retinitis with hæmorrhages. Dr. Bristowe then considered the case to be one of cerebral tumour. The patient gradually got worse, and died comatose on Feb. 12th. At the necropsy the spinal cord and membranes of the brain were healthy. The arteries were atheromatous. A blood-stained area, the size of a threepenny-piece, was seen on the surface of the posterior part of the left optic thalamus; this was the

Digitized by Google

external evidence of a large cavity, the size of a pigeon's egg, containing partly decolourised clot, in the optic thalamus. The hæmorrhage had also ruptured the posterior limb of the internal capsule, and extended into the white matter of the temporo-sphenoidal lobe. The lenticular nucleus was also damaged at its posterior part. The heart weighed 17½ ounces, being much hypertrophied; the kidneys were healthy. Dr. Bristowe remarked on the unusual position of the hæmorrhage and the rarity of the association of such optic neuritis with simple cerebral hæmorrhage.—Dr. HUGHLINGS JACKSON considered that the case was one of great rarity, and he did not think he had seen one like it. Hæmorrhage from cerebral tumour might lead to a mistake. A large blood-clot might be regarded as a foreign body. The fact that there was conjugate deviation of the eyes and head for from five to six weeks was remarkable, for this symptom was usually transitory. — Dr. S. SHARKEY said there was no evidence of glioma in the tissue around the clot. He could not say what the cause of the hypertrophy of the heart was. There was no doubt of the extreme rarity of optic neuritis associated with ordinary cases of hæmorrhage, which usually occurred in the anterior portions of the internal capsule. In the present case there was rupture, and not mere pressure on the posterior third of the posterior segment of the internal capsule, and the lesion had damaged also the optic radiations of Gratiolet. He suggested that an explanation of the occurrence of optic neuritis might be found in the unusual position of the hæmorrhage, damaging at the same time both sensory and motor paths.

Mr. PRIESTLEY SMITH read a paper on Primary Glaucoma in relation to Age. With the help of members of the Society he had collected 1000 cases of primary glaucoma, and had classified them according to the age at which the disease began, the sex of the patient, and the type of the glaucoma. From these actual cases calculations had been made with the help of life-tables to show what the distribution would be if persons of both sexes and all ages were equally numerous. These statistics represented the relative liability of persons of different ages and the two sexes. The results were shown in a series of tables and charts. The following facts appeared:—1. Primary glaucoma is extremely rare in childhood and youth. 2. Its frequency increases, slowly at first, then more rapidly up to the sixth decade; between sixty and seventy it is about as frequent as between fifty and sixty; after seventy its frequency declines. 3. Cases beginning after fifty are about twice as numerous as cases beginning before fifty. 4. Females suffer in rather larger number than males. 5. The non-congestive form is commoner in males than in females. 6. The congestive forms are much commoner in females than in males. 7. The liability is extremely slight in childhood and youth; at least 100 times less in the second decade than in the seventh. 8. It continually increases up to the seventh decade; between sixty and seventy it is at least twice as great as between forty and fifty. 9. After seventy years of age the liability appears to diminish, but the statistics cannot be relied upon, for very old people are less able to come up for treatment than those who are younger. Figures were quoted from the Manchester Eye Hospital Reports in proof of this assertion. 10. The liability of females is rather greater than that of males. 11. The extra liability of females pertains to the whole of life, except perhaps to the periods before thirty and after seventy, concerning which the data are insufficient for generalisation. 12. The extra liability of females relates to the congestive forms of the disease, not to the non-congestive. These results were applied by the writer as a test of the theory of glaucoma arrived at by other means. This first investigation, eight years ago, had led to the inference that change of form in the crystalline lens was concerned in producing glaucoma. A further inquiry arising therefrom had shown that the lens continues to increase in size throughout life. The present inquiry was undertaken to ascertain whether the liability at different periods of life was such as to confirm the supposed influence of the lens. The pathological theory to be tested was, briefly, as follows. As age advances the lens steadily encroaches on the space in which it lies, for the structures which surround it attain their full dimensions early in life. This brings its margin into closer and broader relation with the ciliary processes and lessens the depth of the anterior chamber—changes which, though ordinarily compatible with the integrity of the eye, involve an increasing liability to glaucoma. The highly vascular processes vary much in size according to the quantity of blood in their vessels, and if the space available for such variations be unduly encroached on, they are restricted in the direction inwards, and are forced to expand forwards; in so doing they press forward the base of the iris and narrow the angle of the anterior chamber, causing obstruction of the filtration channels—i.e., glaucoma. Evidence on these points had been published by the author in previous papers. He then proceeded to discuss the several predisposing and exciting causes of the disease, and showed that the analysis of his statistics gave strong support to the theory connecting the increasing liability to glaucoma with the continuous growth of the lens. He concluded by drawing an analogy between an acute glaucoma and a strangulated hernia. In the displacement of the bowel we have a condition, mechanical in its origin, which for a long period of time may have no serious consequence, but which may at its very outset, or at any later time, under a slight constriction, be transformed into one of acute and dangerous strangulation, with intense engorgement of vessels and outpouring of serum in the directions of least resistance. In the eye threatened by glaucoma we have an unfortunate relation of parts, which, though not itself a disease, may lead, through a little further encroachment upon the already narrowed space, to one of the most formidable of ocular disorders, involving stoppage of the intra-ocular currents, throttling of the circulation, and escape of serum into the transparent medium and the conjunctiva. Just as the taxis will occasionally remedy the displacement and terminate the danger in the one case, so, in a few instances, will eserine reopen the outlets and relieve the tension in the other; but just as in strangulated hernia it is generally necessary to at once relieve the constriction with the knife, so in most cases of acute glaucoma our only means of cure is to promptly unlock the eye by iridectomy.

Dr. ARGYLL ROBERTSON read a paper on the Operation of Central Blepharoraphy after enucleation. Many patients were unable to afford the expense of an artificial eye, or were unable to replace artificial eyes, or else the resulting conjunctival cavity was unfitted for the adaptation of an artificial eye. In these cases considerable deformity and discomfort were liable to arise in connexion with the conjunctival sac; papillomatous growths might arise, or the upper lid fall in and the lower one gravitate downward, leaving the conjunctival sac exposed to various irritations. To prevent these consequences, Mr. Streatfeild about twelve years ago recommended the removal of the conjunctival sac by dissection and caustics after enucleation had been done. Dr. Argyll Robertson considered that a central blepharoraphy would prove simpler and quite as effective in preventing the evil consequences of enucleation. The lower lid is grasped with a pair of stout forceps held parallel to the edge of the lid, and the conjunctival covering of the free edge of the lid is dissected off with a cataract knife to the extent of five or six millimetres, corresponding to the centre of the lid, care being taken not to damage the roots of the eyelashes. The upper lid is treated in the same way. Both are brought together by means of a horse-hair ligature. No drainage is needed. Healing takes place readily by first intention, and on the fourth or fifth day the ligature may be removed. The operation could also be employed for long-standing spasmodic ectropion of the upper eyelid. In this affection the tarsal cartilage has a faulty curvature imparted to it. After the eyelid has been kept by the central blepharoraphy in its natural position for some time, the tarsal cartilage regains its normal curvature, and the adhesions may be divided. Dr. Robertson had operated on two such cases with very successful results.—Dr. BRAILEY said the operation had been performed for some years past at Guy's in cases of corneal opacity.—Mr. J. TWEEDY had employed a kind of peripheral blepharoraphy, leaving a central fissure through which vision was possible, in cases of painful ulcers of the cornea and in ectropion of the lower eyelid due to caries about the orbit. He mentioned the case of a lady who had had this peripheral operation performed five years ago, and who refused to have the adhesions broken down because she felt so comfortable in her present state.

Mr. ADAMS FROST exhibited a model demonstrating the Movements of the Eyes. The eyes were represented by two wooden spheres, each movable in all directions round its centre by means of a double gimble-joint. The muscles were represented by cords, having points of attachment and lines of traction exactly similar to those of the natural muscles. The cords were acted upon by rotating three

Digitized by Google

drums, upon which they were wound. The upper of these controlled the lateral recti rotation in one direction, producing conjugate movement to the right, and in the other to the left. This drum was divided in its centre, so that if the halves were rotated in opposite directions, convergence or divergence was produced. The second drum acted upon both superior or both inferior recti, according to the direction in which it was turned, while the lowest acted upon the superior or inferior obliqui in the same way. Any of the natural movements could be produced by combinations of these movements. The ingenious suggestion to divide the uppermost drum to produce convergence or divergence was due to Mr. Paxton, of Messrs. Pickard, Curry, and Paxton.

The following card specimens were shown:—Dr. E. Clarke: Rare form of Vitreous Opacities in a case of High Myopia. Mr. Hartridge: (1) Double Glaucoma in a girl aged fifteen; (2) Congenital Small Lenses in a girl whose sister also had the same peculiarity. Mr. Brudenell Carter: a Spiral Perimeter.

The Council of the Society wishes to collect facts in reference to the symptoms, pathology, and treatment of exophthalmic goitre. The meeting to be held on May 6th will be specially devoted to this purpose. Communications, whether written or *vivâ voce*, which bear upon any or all of the following topics, will be acceptable.

1. Cases in which a necropsy was obtained. 2. Cases in which any definite cause could be assigned for the affection. 3. Abortive cases, that is, cases in which the usual symptoms were present for a short time, and in a slight form, and then disappeared. Are such cases common? 4. Cases which have ended in recovery. 5. Cases which have been kept under observation for long periods. 6. Cases which appeared to be definitely benefited by treatment. Do many cases get well when untreated, and if so, what is the duration of the disease in them? 7. Cases in which the exophthalmos was such as to threaten the safety of the eye, or to destroy it. What are the best measures of treatment with regard to this special danger? 8. Cases in which symmetrical exophthalmos has been observed without the other symptoms of Grave's disease. 9. In what order do the following symptoms usually appear and disappear:—(*a*) Palpitation and throbbing of carotids; (*b*) enlargement of the thyroid; (*c*) proptosis; (*d*) Graefe's lid sign? 10. Does Graefe's lid sign occur when there is no proptosis? Is it equally developed on the two sides? Does it ever accompany prominence of the eyeball due to other causes? Does it occur in hypermetropia, or myopia, or in healthy persons? Do such drugs as cocaine, eserine, and atropine produce anything like Graefe's sign? 11. Is the enlargement of the thyroid usually equal on the two sides? 12. In conjunction with what other diseases is exophthalmic goitre found? Does it occur often in several members of the same family? 13. This disease occurring most frequently in women, is any relation between it and derangement of the reproductive system observable? 14. Family histories of cases of the disease. 15. Has any similar condition been observed in any of the lower animals? Those who make oral communications will be restricted to a quarter of an hour, and will be expected to supply a written report of their remarks. Those who make oral communication of facts will not thereby be debarred from subsequently taking part in the discussion.

OBSTETRICAL SOCIETY OF LONDON.

Anatomy of Labour.—Sarcoma of Vagina and Uterus.

A MEETING of this Society was held on Wednesday, March 3rd, Dr. Potter, President, in the chair.

The following specimens were shown:—Dr. W. S. A. Griffith: Tubercular Disease of the Fallopian Tubes. Dr. Champneys for Dr. Fly Smith: Pellets of Corrosive Sublimate. Dr. Lewers: Cancerous Uterus extirpated by the Vagina. Dr. Playfair: A Calculating Ruler for fixing the Precise Date of Labour. Dr. Godson: A Double Monster of the Syncephalic ineops variety.

Dr. BARBOUR of Edinburgh showed a most interesting series of frozen sections, drawings, and diagrams illustrating the anatomy of the first stage of labour, of the third stage of labour from four cases of Porro's operation, and of the condition at the close of the labour from two cases of death post partum. He drew attention to the value of frozen sections, but did that allowance must be made for post-mortem changes and to those due to the posture in which the cadaver was frozen. The points of chief interest in the first group were the remarkable thickness of the lower segment of the uterus, the course of the ureters, and the disposition of the peritoneum and cellular tissue. The Porro preparations showed the contraction of the uterine wall and diminished placental area. The membranes are crumpled and partially detached, but the placenta is not separated. The placental site may therefore be diminished without the placenta being separated. He concluded that it was separated by detrusion. The absence of space into which it could bulge, the absence of hæmorrhage between the placenta and uterine wall, are against the mode of separation described by Baudeloque, Schultze, and Ahlfeld. These sections bore out the description of the method of expulsion so lucidly described years ago by Dr. Matthews Duncan. The chief point of interest demonstrated by the third group was the large amount of cellular tissue between the cervix and bladder.—Dr. MATTHEWS DUNCAN was astonished at the amount of good and original work which Dr. Barbour had laid before the Society. He referred to the length of time which had elapsed since William Hunter published his work on the gravid uterus, which was supposed to finish the subject. Frozen sections or homolographic anatomy had since done much to increase our knowledge, and now Dr. Barbour had passed from the anatomy of pregnancy to the anatomy of labour—a new field. Frozen sections could not be entirely depended upon to display the conditions during life, but they were of great value. Braune's plate of the anatomy of the second stage was of great value, but was notably misleading in some points, such as the position of the bowels, uterus, and peritoneum. Similar errors had been referred to by Dr. Barbour in his own sections. Dr. Duncan was reluctant to adopt Barbour's theory of the detrusion of the placenta. He had a strong liking for the shrinking site theory, because it combined separation and arrest of hæmorrhage. Everything connected with flooding was of great importance, and therefore he hoped to see Dr. Barbour's views thoroughly sifted. One great fact he had given, that with the site reduced to four inches in diameter the placenta might remain attached. — Dr. CHAMPNEYS, while greatly admiring Dr. Barbour's work and beautiful specimens, dissented from some of the conclusions drawn from the Porro specimens. Illustrations drawn from them as to the physiology of the third stage of labour could only be accepted when consonant with its clinical course. The flattened form of the uterus with the entirely adherent placenta seen in these preparations was contrary to the condition observed in nature, as where women had been examined by the introduction of the whole hand immediately after the birth of the child the placenta had been found entirely detached. Again, he could not agree with Dr. Barbour that these preparations prove that at the beginning of the third stage of labour there is no uterine cavity; its shape proves that it does not alone contain the placenta lying flat against the uterine walls, as in these preparations. Lemser advocated the "detrusion" theory from experiments on pregnant rabbits, but it must be accepted with caution, as the similarity between them and the human female is only slight. Dr. Barbour did not appear to rest on Lemser's observations, but arrived at his conclusions by a process of elimination of the other theories. The mode in which the placenta presents at the os uteri is an indispensable test as to the correctness of views as to its mode of separation.—The PRESIDENT tendered the thanks of the Society to Dr. Barbour for his demonstration, which were very cordially given, and Dr. Barbour replied.

A paper by Dr. LEWERS, describing a case of Circumscribed Sarcoma of the Vagina and Uterus, was then read. The patient was a married woman of fifty, with eight children, and was admitted into the London Hospital on June 27th, 1885. She had had three attacks of flooding, unattended by pain, but each followed by fainting and vomiting; was losing flesh, and had a dirty-coloured vaginal discharge. A lump now protruded from the vulva. She had had an attack of flooding nine years ago, then was regular for six years, and had another attack. The mass on examination was seen to be trilobed, and it was attached to the posterior vaginal wall by a broad pedicle. There was a second mass on the right side as large as a walnut. The uterus felt heavy, but was mobile. The growths were removed on July 2nd, and the patient died of septicæmia on the 7th. At the post-mortem three circumscribed growths were found in the uterus, and there were numerous small secondary growths in both lungs, but none elsewhere. Microscopic examination showed

Digitized by Google

the growths to be mixed, round, and spindle-cell sarcomata. Dr. Lewers thought that the uterine growths were probably the primary ones. There were no lung symptoms during life.—Dr. GERVIS gave details of a case of vaginal sarcoma upon which he had operated three times at lessening intervals, and which now again required operation. It was a small round-celled sarcoma.—Dr. W. DUNCAN was doubtful whether cases of sarcoma of the uterus and vagina should be operated on at all, as a radical cure was improbable.—Dr. M. HANDFIELD JONES mentioned the case of a girl aged sixteen upon whom he had operated a year ago, who still remained in good health. He thought if the growths were removed early enough there was a reasonable prospect that they would not recur. — Mr. KNOWSLEY THORNTON pointed out that it was often necessary to operate for the comfort of the patient, and could not think that the chance of recurrence was a ground for leaving the patient in misery, and each operation would give her at any rate a period of health and hope. The recurrence at lessening intervals was familiar to surgeons in all sarcomata, and hence the old name given by Sir James Paget to these growths, "recurrent fibroid."—Dr. ROUTH advocated the removal of these growths and the destruction of their site with strong caustics, such as nitric acid and bromine. He mentioned a case in which after a third operation there was no recurrence. — The PRESIDENT and Dr. HORROCKS also spoke, and Dr. LEWERS replied.

At the close of the meeting, the PRESIDENT announced that in future the Transactions would be published in monthly or bi-monthly parts; but those Fellows who preferred it could still have the volume sent to them as heretofore at the end of the session.

HARVEIAN SOCIETY.

Chronic Rheumatic Arthritis of the Hip-joint.

A MEETING of this Society was held on Thursday, March 4th, J. Hughlings Jackson, M.D., F.R.S., President, in the chair.

Mr. W. ADAMS read a paper on Chronic Rheumatic Arthritis of the Hip-joint. He described at length the structural changes occurring in the later stages of the affection, and suggested that all the old museum specimens showed that the cases might be arranged in three classes. 1. In which the bones are increased in density and weight; the femur in these cases showing no depression of the head or any absorption or alteration in the angle of the neck. Ring-like masses of bone were thrown out; the articular cartilages were eroded, but the surface of exposed bone was not absorbed. Eburnation took place in the direction in which motion had been preserved. The outgrowths of bone were produced by ossification in the articular cartilage, as proved by the author in a paper read in 1851 (Path. Soc. Trans., vol. iii.), by ossification of the synovial fringes, and by outgrowths from the periosteum. 2. In which atrophic changes predominated, producing in the hip-joint a smaller head and depressed neck of the femur, the nodular outgrowths being less marked. 3. In which the atrophic and hypertrophic conditions were combined. After expressing his belief in the causative influence of rheumatism and gout, the author proceeded to discuss the relation of these joint affections to locomotor ataxy and other nerve diseases, and to contrast rheumatic arthritis with Charcot's disease.

Rheumatic Arthritis.	*Charcot's Disease.*
1. Changes chiefly hypertrophic.	1. Changes chiefly atrophic.
2. Commences in the soft tissues.	2. Commences in the bones.
3. Painful throughout its course.	3. Generally painless.
4. Pain confined to the joint.	4. Pains shoot through the limbs.
5. No febrile disturbance; no gastric or ocular symptoms.	5. All these symptoms are present.
6. Reflex symptoms present.	6. Reflex symptoms absent.
7. Limited mobility.	7. Flail-like mobility.
8. Progress slow and chronic.	8. Progress rapid and acute.
9. Patients often reach old age.	9. Patients seldom reach old age.

The influence of injury in the production of the disease was then discussed, and the paper was concluded with remarks upon treatment, the value of local sweating by means of hot vapour being insisted on, coupled with shampooing and passive movement. The hot sulphur springs of Luchon, in the Pyrenees, were especially commended. — Dr. BUZZARD observed that the results of ordinary treatment in chronic rheumatic arthritis were eminently unsatisfactory, the disease generally going from bad to worse. In some cases of joint disease associated with locomotor ataxy, however, a remarkable regression of symptoms might take place, the patient recovering full use of a hitherto useless limb. In Charcot's disease, again, there was often a remarkable degree of hydrarthrosis of the joints, frequently extending far beyond the joints themselves; extreme weakness of ligaments and a tendency to atrophy in the bones were also to be noted. He thought it probable that by the study of Charcot's disease means would be found to explain the phenomena of rheumatic arthritis. If the disease were due to a central nerve lesion the tissues of the spinal cord might safely be eliminated. The results of sclerosis of almost every part of the cord were well known. Very many of the symptoms combined to indicate the medulla oblongata as the original seat of the mischief; the gastric and laryngeal crises, the heart symptoms, and the sweating all pointed to the probability that the centres for the vaso-motor system and for the osseous and articular system must be situated close to one another. In rheumatic fever, the acute affection of many joints, the high temperature, cardiac disturbance, and sweating all served to illustrate this in a marked degree. He looked upon rheumatic fever as an acute affection of the medulla oblongata, and suggested that chronic rheumatic arthritis might possibly be due to a chronic form of the same lesion. He regarded Charcot's disease as a chronic affection of a certain part of the medulla, spreading to the vaso-motor centre, and causing changes in the nerves supplying the bones and joints.—Dr. CLEVELAND referred to the connexion between alcoholic intemperance and chronic arthritis, and expressed an opinion that alcoholism played a principal part in its production, especially among women. — Dr. W. H. BLENKINSOP believed that the failure of treatment was often due to want of persistence in it, and related a case to prove the value of continued treatment. He advocated the use of dry vapour to produce sweating, in preference to steam.—Mr. GANT expressed his belief in the efficacy of Scott's dressing, and mentioned a case in which the disease so treated had been kept in check for twenty years.—Mr. SPENCER WATSON referred to the occurrence of acute inflammation of the eye in these cases.—Mr. NOBLE SMITH asked whether the same symptoms had been noted in the affections of the hip-joint in later life as were characteristic of the acute affection in childhood? He had had very good results from treatment by iodide ointment, where other applications had failed. He thought that the influence of alcohol was traceable in many of the joint cases in the British Home for Incurables.—Dr. MORTON inquired as to the use of passive movement in treating cases of chronic joint disease arising from injury.—Mr. J. E. LANE mentioned that the atrophic changes in hip- and shoulder-joints, exactly like those of Charcot's disease, were frequently found in dissecting-rooms. He related a case of excessive effusion into the shoulder-joint, in which complete recovery took place, in the presence of locomotor ataxy. The treatment pursued at Aix was most satisfactory, the shampooing especially being very effectively carried out.—Mr. W. ADAMS, in reply, expressed some doubt whether alcoholism had much to do with the production of the disease. In cases where the joint affection was thought to be due to accident there was generally a history of antecedent rheumatism or gout.

Reviews and Notices of Books.

The Optical Manual, or Handbook of Instructions for the Guidance of Surgeons in Testing the Vision of Recruits, &c. Third Edition. By Surgeon-General T. LONGMORE, C.B. London: Clowes. 1886.

SOME eleven years have elapsed since the appearance from the pen of Professor Longmore, of the Army Medical School, Netley, of the second edition of the "Ophthalmic Manual for Army Surgeons," and, considering the value of the trained soldier to the State, the importance to the officers of the medical service of the army of a thorough knowledge of the subject of which the manual treats, cannot be over-estimated, more especially in regard to the rules laid down for guidance in distinguishing optical defects amongst officers and men already engaged in the military services of Great Britain.

As might be expected, in view of the rapid strides that

Digitized by Google

have been made in this branch of medical science within recent years, Professor Longmore has found it necessary to rewrite and enlarge the present edition, so that practically it now appears in the form of a new work. Chapter I. is devoted to the consideration of the eye as an optical instrument; the hygiene of normal vision is explained, the necessity to the soldier of unimpaired binocular vision in judging and in the use of the rifle is dwelt upon, and the various optical appliances are given and described in detail. In the following chapters the functional pathology of the eye is entered into, and the method of conducting the visual examination of recruits, with an account of the qualities of sight which are requisite, or which lead to disqualification or non-efficiency amongst officers and men in the different branches of the army and of the navy; the various errors of refraction are clearly enunciated and explained, together with their treatment and hygiene, also the method of diagnosing them and the disqualifying degree of each. The chapter on the assessment of ocular refraction is carefully written, and brings home to the army surgeon that he will find an acquaintance with the use of the ophthalmoscope, as a means for gauging the sight value of an eye, as necessary as that of the stethoscope in testing the conditions of the respiratory or circulatory system.

We regret to learn from perusal of the manual that, in consequence of complete sets of trial lenses not being supplied for use in the army, medical officers are unable to have recourse to keratoscopy, which is an invaluable aid in the estimation of visual capacity, and trust that the authorities may be induced to supply a full set to the head-quarters of each recruiting district and each large military hospital.

The mechanism of accommodation is fully entered into, as well as the anomalies of binocular and associated vision; also the relationship of strabismus to myopia and hypermetropia. Part of Chapter V. is devoted to colour-blindness and its detection. The possession of correct ideas regarding colour is of great value in a vast number of callings, and inability to distinguish them may be the source of the greatest peril in case of persons placed on watch, as at sea. The distinction between congenital and acquired dyschromatopsia is clearly explained. The subject of hemeralopia is described under the head of amblyopia, and is of extreme interest to the army surgeon, as, apart from being a symptom of organic disease, it is often met with abroad as a transient condition due to hygienic causes solely, and in the case of the soldier is, of course, a serious disqualification. The important condition of asthenopia, so often connected with ametropic states of ocular refraction, myopia, and hypermetropia, is fully discussed. The necessity to the recruit or soldier of having the visual area intact, as well as the requisite central acuity, is dilated upon, the loss of a portion of the field of vision not only unfitting a soldier for military duty, but may be a symptom of serious progressive disease—a fact which should be borne in mind by all who are called upon to test vision, and especially by the army surgeon.

In the third edition of the "Optical Manual" the Professor of Military Surgery at Netley has placed the principles of the more abstruse portion of modern scientific ophthalmology within the reach of all who have to examine persons seeking employment in the various public departments; and, keeping in view the recent advances in optical appliances and manipulation, and such as have been made in respect of length of range and capacity for firing of the weapon at present in use in the army, has applied them to the actual conditions of service, thus supplying the profession at large and the army surgeon with a valuable *aide mémoire*.

Hernia, and its Radical Cure. By JOHN WOOD, F.R.S., F.R.C.S., Vice-President and Hunterian Professor of Surgery and Pathology in the Royal College of Surgeons, &c. Pp. 124. London: Henry Renshaw. 1886.

THIS admirable little work consists of three lectures delivered by the author at the College of Surgeons in 1885, and a lecture on "The Application of Trusses to Hernia" given at King's College Hospital. Every page is stamped with the well-known acumen of the writer, both as a surgeon and a practical anatomist.

The first chapter is devoted to an analysis of the cases operated upon by Mr. Wood, to the Pathology and Causes of Inguinal Hernia, and to the Anatomy, general and applied, of the Inguinal Region. From this we learn that the author has, in all, operated upon 391 cases: 370 inguinal, 16 crural, and 5 umbilical. "In 11 cases the hernia was double, and both sides were operated on; in 12 cases, operations which at first failed were repeated (in 2 cases three times); making a grand total of 414 operations." In a subsequent chapter we find that out of 339 operations for reducible inguinal hernia 248 operations were successful, and the number of ascertained failures 59; thus giving 73 per cent. of successful cases. Out of 273 cases of the wire operation alone there were only 4 deaths—about 1¼ per cent.,—none of which could be strictly attributed to the special conditions and results of he operation. Of the whole 339 operations by varioust methods there were 7 deaths, or about 2 per cent. In 28 cases, where the sac was tied with catgut and removed and the sides of the canal and rings drawn together, 3 died, or about 11 per cent.—a mortality, as Mr. Wood observes, too great, if maintained, to justify an operation of expediency.

The third chapter embraces the Anatomy and the Operation for Radical Cure of Crural and Umbilical Herniæ, Choice of Cases for Operation, Review of the various Methods of attempting a Radical Cure of Hernia in Ancient and Modern Times, and a Classification of Cases for Selection of Operation. The closing chapter on the Application of Trusses will be read with interest and profit both by hospital surgeons and general practitioners.

The entire work is a closely reasoned argument and critical review of facts; in short, it must be carefully studied by those who would duly appreciate its merits. It shows, if indeed this were needed, that Mr. Wood is *facile princeps* in all that pertains to the curative treatment, of the application of which his recent monograph treats.

"MR. HORSLEY'S CRITICISM OF PROF. SCHIFF."

To the Editor of THE LANCET.

SIR,—There is one little point a trifle weak in Mr. Horsley's wit. The Brown Professor is facetious, not about what Schiff did say, but about what he did *not* say. Professor Schiff, as quoted by me (THE LANCET, Feb. 20th), says: "Now I understand what Mr. Horsley means by the motor tract. He believes that the posterior part of the lateral columns near the posterior horns of the grey substance is motor. This is a very general opinion, against which I shall publish a series of experiments." According to Professor Horsley, however (THE LANCET, March 6th), "Dr. Huggard quotes Professor Schiff (*verbatim*) as saying that although the opinion that the crossed lateral (pyramidal) tract is motor is a very general one, he (Professor Schiff) is going to prove that it has no such function." To find an identity of meaning between what Professor Schiff did say and what Professor Horsley says he said would puzzle anyone.

The experience of Professors Ptthmllnsprts and Horsley is evidently to be trusted. The aforesaid variety of breakfast appears to aid a person considerably in proving a thing "at least to his own satisfaction."

I am, Sir, your obedient servant,

Davos Platz, March 9th, 1886. WILLIAM R. HUGGARD.

THE LANCET.

LONDON: SATURDAY, MARCH 20, 1886.

THE long-expected Report of the Committee on the mode of obtaining the Fellowship of the College has at last been presented to and adopted by the Council, and made public. It is satisfactory to find not only that the rumour of making Fellows wholesale without examination has proved false, but also that some very reasonable changes are proposed instead.

The Council recommend two methods, by the first of which every year a certain number, not exceeding ten, of the Members of the College, of not less than twenty years' standing, who are distinguished by scientific or professional ability, or by good service rendered to the profession or the public, shall be elected to the Fellowship. To such a proposal there can be no valid objection, provided always the recipients are really distinguished for special surgical knowledge, and that not necessarily *ten* are elected *every* year. Such a rule as this will have to be very judiciously carried out, otherwise it will be capable of being used for party purposes, and made to serve other ends than the promotion of the study of the art and science of surgery.

By the second method proposed, Members of not less than fifteen years' standing are to be exempted from the first Professional Examination for the Fellowship—that, viz., in Anatomy and Physiology,—and would be required to pass only the Second Examination, as defined by the present regulations. We think this plan much preferable to the former, and one likely to further the purposes for which the Fellowship was instituted. There are many other causes, over and above want of ability, which may interfere with a student's passing the Primary Examination in Anatomy and Physiology, and it has always appeared to us regrettable that an examination in subjects of minor importance to the practitioner, and which can only be properly studied in the schools, should prove the chief barrier to the acquirement of this highly prized surgical qualification by those engaged in practice. This proposed change in the rules for admission to the Fellowship will be welcome to many provincial surgeons, and afford them the opportunity of acquiring the diploma which their line of practice and their surgical attainments will permit them to wear, without either detracting from its dignity or subverting the purposes its founders had in view when instituting it.

The Council, furthermore, propose to make a new class of Fellows—viz., Honorary Fellows, to consist of persons, whether Members of the College or not, who have rendered distinguished service in the advancement of surgery or the sciences allied to surgery. We hail this last proposal as a most important step forward, as one which will bring the College into something like keeping with other scientific corporations, almost all of which have the power of affiliating to themselves eminent men of any and every nationality. We could wish to see the proposal somewhat enlarged. It would be desirable to fix the *total* of Honorary Fellows rather than limit the number to be elected every year. *Forty* suggests itself as a possible maximum after the manner of some other distinguished bodies. This number would easily be attained, even should the highest standard be insisted on, provided other countries than England were duly honoured and represented. The number once completed, the Council would then fill up vacancies as they occurred.

It is expressly stated that the Honorary Fellows are to be exempted from the payment of fees. This is as it should be. It is something humiliating that the Royal College of Surgeons of England should not only have had to wait until a man like HUXLEY, for instance, had been a Member for twenty years before being able to confer the Fellowship, but also that it should be obliged to demand a fee for admitting the most eminent biologist of the day to a diploma which becomes enhanced in value by being accepted by such a man. Nothing is said concerning the payment of fees by those who become Fellows under the other proposed new rules. It must be taken for granted, however, that, in accordance with the recommendations of the Committee on Charters and Bye-laws (presented to the meeting of Fellows and Members on Oct. 29th, 1885), Members *elected* to the Fellowship will be exempted from the payment of any fees; on the other hand, those Members of fifteen years' standing who decide to offer themselves for examination and pass, will be called upon to pay a fee—an obvious injustice. For both sets of Members will gain about the same by becoming Fellows, while those who pass the examination will deserve even more consideration than those who simply drift in by election. Clearly this question of fees will require reconsideration; a fee ought to be exacted from all who are in practice on becoming Fellows, whether by election or examination.

While we cordially approve the latest proposed changes in the mode of conferring the Fellowship, we cannot refrain from again pointing out how these proposals stultify some previous official utterances concerning these same questions which the Council have promulgated. For example, in the last report presented at the October meeting of Fellows and Members, the Council, in answer to the repeated and persistent recommendation of the Association of Fellows that an order of Honorary Fellows should be instituted, said it could "not recommend the institution of a class of Honorary Fellows." This answer was repeated in December, and yet in March the Council adopts the recommendation, but apparently without acknowledgment of the Association of Fellows. Nor can we forget that, notwithstanding the representation of the Association of Fellows and the views expressed at the meetings of the Fellows and Members, the Council a few months ago publicly announced their determination to take steps to secure the necessary powers for giving effect to proposals which they now tacitly admit to be faulty. Even on so obvious a question as that of Honorary Fellows, the Council have several times decided in the negative. We ought not to reproach the Council for at last deciding to do what is right, and what we have so often advocated in these pages. Nor do we. What we lament is the absence—which this weathercock policy implies—of any political capacity in the Council. There is no intelligent grasp of the situation, nor appreciation of the changes required in the management of the College, and in its

Digitized by Google

relations with the Members at large in order to place the College *en meilleur rapport* with the natural aspirations of its highly educated constituency and with the altered spirit of the times. The Council appears unable to draw up any adequate and complete scheme of reform, and refuses to accept the help of those who are equally interested with themselves in doing everything possible to strengthen and uphold the position and dignity of the College.

NOT many months ago the profession and the public were startled by the announcement that M. PASTEUR had carried the scientific speculation on the possibility of preventing hydrophobia in the human subject within the range of practical pathology and medicine. There were few then who added expectation to hope that the learned experimentalist would in so short a time make headway against the apparently insuperable difficulties of the situation. To-day, however, it may be truly said that the four corners of the earth are ringing with the record of his brilliant exploits and triumphal progress. People who have had the misfortune to suffer from the bite of dogs, cats, and wolves —mad or otherwise—are crowding to the metropolis of sunny France to undergo inoculation with the attenuated virus of rabies, prepared from the nerve centres of animals recent victims of the deadly scourge. England, Russia, America, Hungary, and other countries, by the aid of State and private enterprise, are sending patients to M. PASTEUR'S laboratory for the purpose of testing the value of his "specific" treatment. Contrary to the dogmas of metaphysicians, who assert that there is always a hostility to new experience, we find votaries ready and numerous to stake the chances of failure, and even of danger, against the possible attainment of immunity from the consequences of an anticipated disease. Nor, considering the horribly grim event which none can contemplate with complacency or foretell with certainty, and the final result of which, when developed, it is doubtful if anyone has hitherto been able to avert, is it surprising that men should hasten to avail themselves of an antidote, be it rational or empirical, of merely vaunted repute or proved efficacy. There is something more, however, than humanitarian sentimentality involved in the consideration of M. PASTEUR'S enterprise—an enterprise destined to lead to one of the greatest achievements of the age, or to end at least in a splendid scientific failure. It must not be supposed, because the author of all this wonderment and admiration stands, as it might appear, upon the fitful tenure of the sufferance of those who look for much and hope for more, yet may nevertheless be as ready to condemn anon, as they are now prepared implicitly to trust, that he has been led to deeds of daring by purely fortuitous circumstances. M. PASTEUR'S reputation, acquired as it has been by years of laborious research and keen logical inference, is a sufficient answer to such an assumption. Moreover, the past history of medicine furnishes analogical grounds for regarding the investigations now in progress as likely to succeed in the long run. Hydrophobia, like small-pox, is a disease arising from the action of a specific poison, and we know what untold good has accrued from the discovery of our own JENNER. Vaccination, or in other words, inoculation with what is practically an attenuated virus, has established itself so firmly in the world's confidence that in most civilised nations it has become a State institution, and that too in spite of long-continued and strenuous opposition. Then there are "many who believe that vaccinia is identical in its nature with variola, only modified by its occurrence in another animal, and there have been many observations and experiments which seem to support this notion" (ROBERTS). It is also known that if "an unvaccinated person inhale the germ of small-pox on a Monday and be vaccinated as late as on the following Wednesday, the vaccination will be in time to prevent small-pox being developed." This is exactly the principle which M. PASTEUR is carrying out, and fortunately the long period of incubation of hydrophobia gives a wider limit to the chances of success from inoculation. Again, hydrophobia is only conveyed by direct contagion, so that the date of introduction of the poison into the system can be fixed with precision—an argument in favour of delaying the inoculation with attenuated virus until infection with the more deadly "cause" has become an accomplished fact. On the other hand, small-pox is almost invariably communicated through the atmosphere, and as there are no immediate effects, the all-important period is not known, and the opportunity of saving the patient from the consequences of the infection is lost. In process of time it may become the fashion to inoculate with the mitigated virus in order to give protection against the possible bites of mad dogs, but at present there seems little likelihood of this practice being established, nor, on the whole, is it desirable. That inoculation for rabies is founded on a scientific basis there seems no shadow of a doubt. It only remains to be seen whether M. PASTEUR can establish as an art what appears as a very plausible theory. Of this we may be sure that, guided by the light of his experiences with inoculation as a preventive against splenic fever in cattle, he will avail himself of every assistance that is likely to bring his task to a successful issue. The public and the profession must be prepared for failures, and not expect more than can reasonably be demanded. For the present we trust that M. PASTEUR will receive every encouragement that the State and individuals can render. The enterprise in the interests of humanity is worthy the man, and M. PASTEUR is perhaps of all men most fitted to carry it out.

THE scheme of the Metropolitan Board of Works for the disposal of the sewage of London was produced at the meeting held on the 12th inst., and an abstract of it appeared in *The Times* the following day. It was contained in a report prepared by the Works and General Purposes Committee, which we trust will be published without delay, in order that impartial criticism may be brought to bear upon it. At present we have only *The Times* abstract, and an interesting, although of course non-official, article which appeared two days later in the *Daily News*, to assist our judgment. The utmost publicity should be given to all the proceedings in this difficult and most important matter, for although they are assisted by distinguished scientific advisers, the members of the Board have no right to affect omniscience. It has frequently happened that other scientific men of no less eminence have differed from those who advise them, and it is clearly right that the public should hear both sides of the question.

Digitized by Google

We admit at once, and with pleasure, that the Board has been by no means idle. Many interesting experiments have evidently been made, which will be of permanent value, and of which we should be glad to hear more details. A course of action has, moreover, been decided on which will undoubtedly improve matters, even though it does not promise a permanent solution of the difficulty. We urged a short time ago that alternative schemes should be prepared, and to a certain extent this has been done, for it would seem that several modifications are possible in carrying out the system recommended to the Board by their committee, which has therefore to some extent the elasticity which is so desirable. Probably it will be adopted, and we are inclined, on the whole, to hope that it will.

The scheme which it is proposed to apply to the whole of the London sewage may be divided into three operations—namely, precipitation, separation of sludge by filter-presses, and purification of effluent. This is substantially in accord with the recommendation of the Royal Commissioners, and as such we heartily commend it. Each of these operations must be described briefly in order to render our comments intelligible. First, then, the precipitation. This is to be effected by the addition of 3·7 grains of lime, and 1 grain of proto-sulphate of iron to each gallon of sewage, with subsidence for from one to two hours. The chemists consulted by the Board, Sir F. ABEL, and Messrs. ODLING, WILLIAMS, and DUPRÉ, report that the effluent so obtained "would be a very great gain over the discharge of untreated sewage"—a safe enough statement; and that according to their "present impression, little if any additional advantage would accrue either from an increase in the proportions of the chemicals specified, or from a resort to other chemicals which would act merely as precipitants." They add, however, that the effluent should not be discharged into the river "during warm weather at all states of the tide." The treatment of the sludge is the next point. It is to be reduced to the smallest possible bulk by filter-presses, and the cake given away if anyone will take it, and if not carried by steamer to sea and there discharged. Finally, the effluent water is to be deodorised by the method which has found favour in the eyes of the Board—namely, by mixture with manganate of soda and sulphuric acid. We understand that the quantity of crude manganate is to vary from 0·5 to 1·5 grain per gallon, but *The Times* summary is somewhat indistinct on this point. This is the quantity recommended by the above-named chemists, who, however, are doubtful whether any disinfection is necessary in cold weather. Another precaution has already been taken, and it is proposed to continue it under the new system. At thirteen stations on the lines of the great sewers manganate of soda and sulphuric acid are added with a view to prevent the formation of sewer gas. If this really averts this dangerous source of mischief the expense is well warranted, but we confess to considerable incredulity on the point. If, on the other hand, it is not effectual, there is great danger that a false sense of security will be engendered.

Such is an outline of the methods by which, in all probability, the sewage of London will before long be treated. That they would effect a vast improvement in the condition of the Thames is certain, and we by no means assert that any better system is for the present forthcoming. It is, therefore, in no unfavourable spirit that we approach the task of criticism. To begin with, we are rejoiced to find that precipitation and sludge-filtration are to be the basis of the system. They have given satisfactory results wherever they have been properly tried. As to the chemicals selected we are not so certain, and have no evidence before us that the committee have sufficiently considered the rival claims of the many mixtures which have been proposed. The well-known A B C process, for example, gives an excellent effluent, and it would be interesting to know on what grounds it had been rejected. The process has been worked for many years at Aylesbury, apparently with success, and the experiments made so many years ago at Crossness do not warrant its contemptuous dismissal. The disposal of the pressed sludge is another important point. It is, we suppose, unlikely that farmers will take it, even as a gift, in such enormous quantities as the Board will produce it, and so it must go to sea. The important argument of Sir J. B. LAWES, however, suggests that even in this case it is not necessarily lost, for it may, if well distributed, improve the fisheries along the coast, by supplying the phosphates which go to form the fishes' bones. The Board propose to provide large ships for this purpose—a purpose which at first sight appears wasteful.

As to the disposal of the effluent, we quite agree that it must be disinfected somehow before it goes into the river. At present the sewage must be treated at the existing outfalls, for the danger of the present system is urgent, and some chemical disinfectant must therefore be used. Whether permanganic acid is the best we cannot say; possibly it is. But although it is inapplicable at Barking and Crossness, land-irrigation is a better means of purifying sewage-effluent than any chemical disinfection; and when the sewage goes down to Sea Reach, as we trust it will before many years are past, the final purification will probably be done by the soil, and an almost perfectly pure effluent thrown into the river. The committee are, indeed, so enamoured of their permanganate disinfection, that they have quite given up the idea of moving from their present outfalls. They say, on the authority of the chemists who advise them, that "the necessity for land-filtration no longer exists, and thus the great objection to the treatment of the sewage and the discharge of the effluent at the present outfalls is overcome." To this we most strongly demur. We are more than ever convinced that the sewage of all London ought not, even after chemical treatment, to be thrown into the river at Barking and Crossness; and we decline to receive on this point the assurance of certainty from chemists who three years ago were equally sure that no important injury was done to the river by the raw sewage. We are sorry that the Board persists in this obstinate resistance to the recommendations of the Royal Commission. They have been forced into their present action, after a hard fight, by the pressure of scientific and public opinion, and now, instead of giving in gracefully and obeying the wish of the nation, they contest every inch of ground in their retreat.

THE modifications which, after about a year's experience, it has been found necessary to introduce into the First Examination of the Examining Board in England constitute

Digitized by Google

another step towards the improvement of the medical curriculum, the need for which we have several times pointed out. This examination, as originally framed, comprised two parts—namely, Medical Botany, Chemistry and Chemical Physics (meaning thereby Heat, Light, and Electricity), Materia Medica and Pharmacy forming the first part, for which it was not obligatory on the candidate to have received instruction at a medical school; and Elementary Anatomy and Physiology, for which a six months' study at a medical school was requisite. The changes advised by the Committee of Management, and adopted by the Colleges, include (*a*) the entire omission of Botany from the subjects of examination and the medical curriculum; (*b*) the option allowed to the candidate of taking Materia Medica and Pharmacy either with his Second Examination or with his First, and (*c*) the subdivision of the First Examination into three parts—namely, (1) Chemistry, including Chemical Physics; (2) Materia Medica and Pharmacy; and (3) Elementary Anatomy and Physiology. Since these alterations are to come into force at once, it may be useful to point out their bearings upon medical education.

The disappearance of Botany from the medical curriculum is the inevitable result of the growth of this science and of other more important subjects. As a part of the examination in question it had shrunk to ridiculously small proportions, but its elimination will be felt as a relief by the medical schools as well as by the medical student. The amount of botanical knowledge which the average medical student has hitherto gained is so small as to be practically valueless. Still we trust that this exclusion from the curriculum does not mean the entire banishment of the subject, and once more we would urge that both branches of Biology should be included in the subjects of Preliminary Examination. A lad who intends to study medicine ought to enter the medical school with some previous knowledge of science, and there is no hardship in requiring evidence that he has passed through a period of scientific training, whether at school or after, but at all events previous to his being eligible for a place on the Medical Council's Register of medical students. One argument for the retention of Botany in the curriculum is its practical advantage in the recognition of poisonous plants, but plainly such instruction as is needed for this purpose should find a place in the course of Toxicology. Botanical science cannot be taught any longer within the walls of medical schools, and the curriculum must not be overweighted by it; but as a subject of preliminary education it finds its appropriate place. It must be confessed that the same arguments apply to the study of Physics and Inorganic Chemistry. Although the Colleges do not demand evidence that the student has received his instruction in these subjects at a medical school, the fact that they include them in their First Professional Examination will tend to perpetuate the system of instruction so long in vogue. We are of opinion that both Physics and Chemistry, being subjects which require special laboratory instruction and a very complete training, are not in themselves necessary portions of strictly medical education. Their relegation to purely preliminary education would do much to develop that higher and more specialised chemistry which is termed Animal Chemistry, physiological and pathological. It is notorious that at the present day attendance upon the classes of Physics and Chemistry is regarded by the medical student, unless he have really a bent in their direction, as irksome and unprofitable. It is regrettable that this should be so; for a knowledge of these subjects is essential to a proper understanding of physiology and medicine. Very differently would these instructions be received were they so framed as to be directly applicable to purely medical work; and, therefore, in once again advocating their removal to preliminary education, we are sure that we are advising what is best in the cause of medical study. We venture, then, to urge upon the Committee of Management the serious consideration of the propriety of instituting a Preliminary Scientific Examination *before* registration; and the only reason that we can imagine why this step has not hitherto been taken, is the dread lest by making the entrance into the profession more difficult the number of entries will be much diminished. Such fears are groundless, for a year spent in scientific education is the best preparation for the student's subsequent career,—whilst the present plan, by which, to all but a few, the pursuit of these sciences compels interference with the natural course of professional study, is obviously detrimental from the scientific as well as the medical point of view.

The retention of Materia Medica and Pharmacy as part of the First Examination would matter little if the Natural Sciences were excluded; but it is quite plain that the grace allowed to candidates to defer these subjects to their Second Examination has been forced upon the Colleges by the disastrous issue of the original scheme. The examiners have found that the knowledge of Materia Medica exhibited by candidates has been very defective; with every latitude the rejections have been very high, and the derangement of the student's curriculum proportionately extensive. Since, however, the synopsis includes some knowledge of the medicinal action of the drugs, it would seem more appropriate to allow this subject to be taken with the subjects of the Second Professional Examination, as is the case in the universities; and doubtless the student who enters the schools without any previous knowledge of pharmacy will be advised to defer his attendance upon these classes until his second summer session. By that time he will be prepared to receive instruction upon the medicinal properties—or rather, we should say, the natural action—of drugs with reference to the normal functions of the body; he will study the subject with intelligence, and not by the method of cram. In conclusion, we believe that by these revised regulations the Colleges have taken one step towards a rational system in respect of the earlier education of the medical student; but that these changes must only be regarded as foreshadowing a bolder and wiser policy is to be hoped, and indeed expected, from such esteemed authorities on medical education as Sir H. PITMAN, Professor MARSHALL, and the other members of the Committee of Management.

THE answer which the President of the Local Government Board gave last week in the House of Commons to a question by Mr. GIBB, concerning the influence of the small-pox Hospitals at Hampstead and Highgate, is not calculated to satisfy those persons who reside in the neighbourhood of these or other small-pox hospitals in the metropolis. Mr.

Digitized by Google

CHAMBERLAIN began by pointing out that his Board had no control over the Highgate Hospital, which was maintained by voluntary contributions; and his answer reads as if this were held to be a sufficient reason for the non-interference with an institution which there is too much reason to fear is a cause of loss of life in the north of London. Again, concerning the Hampstead Hospital, he refers to the "expensive litigation" to which it has given rise; as if this were evidence that the effects of the institution upon the public health had not been entirely overlooked. It might not unreasonably be argued that if due regard had been had for these effects, expensive litigation would never have resulted, and certainly, from the ratepayers' point of view, the expenditure of a large sum of money in a contention from which the public derived no benefit might have been conveniently replaced by the expenditure of a much smaller sum in an investigation into the effects of aggregation of cases of small-pox. Mr. CHAMBERLAIN'S answer is, indeed, only useful in one sense. It serves to show Londoners the hopeless condition in which they are placed for want of a central sanitary authority competent to consider these hospitals in their relation to the public health, and not as mere houses for the accommodation of certain sick persons; and it serves to show in its worst light the effect of government by boards which fail to see that the mere carrying out of Acts of Parliament in their legal sense is not the only duty which should be undertaken by authorities claiming to be enlightened.

There is no manner of doubt that a very serious responsibility rests upon the Local Government Board. This Board has had under their notice the expensive litigation in connexion with the Hampstead Hospital, and all the evidence that was forthcoming at the hands of the lawyers who conducted the inquiry. They have had before them the report of their own inspector, Mr. W. H. POWER, as to the mischief done by the Fulham Hospital. They have had the results of an inquiry by a Royal Commission, and a further report from Mr. POWER, showing, as regards Fulham, that, notwithstanding the adoption of some of the Commission's recommendations, the Fulham Hospital has still been mischievous in its effects. But this is not all. Their own medical officer has, in his report for the year 1884, pointedly directed their attention to the fact that "there are not a few indications subsequent to the report of the Commission of 1881 tending to the conclusion that the asylums hospitals in their present shape continue to cause an increase of small-pox in their several neighbourhoods." Nevertheless, the President does not hesitate to tell the House of Commons that since the termination of legal proceedings "the managers have secured an additional area of land in connexion with the site," as if this fact were reason for hoping that the further use of the hospital would not be detrimental to the health interests of the inhabitants of its neighbourhood!

This method of dealing with a subject which is related to the very existence of many people is emphasised by the action of the Metropolitan Asylums Board. A few weeks ago a special committee of this Board, appointed to consider the subject of hospital provision for small-pox, presented their report. This report contains a considerable amount of argument upon the question whether it is more economical to erect a completely new building at Darenth, or whether certain existing structures can be utilised; but from beginning to end there is not a single line upon the all-important question whether the hospitals at Hampstead, Fulham, Deptford, Homerton, and Stockwell are a cause of loss of life to the inhabitants of these districts, notwithstanding the fact that the several medical officers of health of the parishes in which or near which these institutions are situated have definitely shown that there is reason for believing this to have occurred.

There has indeed been too much delay in dealing with this matter. If the issues involved were merely the unwise expenditure of public money, we should be slow to concern ourselves further with it, but the squandering of human life which results from the adoption of a policy which can serve no good end is too serious a consequence to be passed by. Mr. GIBB'S question and Mr. CHAMBERLAIN'S answer in the House of Commons will, we hope, be the means of forcing this subject upon public attention; we trust it may not again be forgotten before it has received a satisfactory settlement.

THE Council of the Hospital Sunday Fund has determined that the question of sectarian nursing is not one for them to settle. Not only by the rules of the Fund, but by its very nature and constitution, there is no room for the discussion of such a question. It is the very glory of the Council to consist of men of every variety of creed, who have agreed, for the sake of helping the hospitals, to sink all sectarian differences and give way to the common religious instinct to befriend the poor and heal them of their sickness. It is an Old Testament representation of the Almighty that "He gives strength to the languishing and makes all his bed in his sickness." Hence it happens that the Bishop of LONDON and Professor MARKS equally feel the desire and the duty to co-operate in this great work. It is gratifying to find that the churches of London generally agree with the Council in this view of their duty to subordinate sectarian questions for the sake of discharging the urgent duties of catering for the sick poor. Many of the dissenting churches feel keenly the exclusion of their members from the nursing staff because of their non-conformity. But, to their great credit, they will adopt other means of removing this disability than by withholding their collections from the great Hospital Fund of June. One of these means is by fair and frank discussion of the question in proper places; and one of those proper places is in the rooms of the Hospitals Association. Accordingly, on Wednesday last, with Sir ANDREW CLARK fitly in the chair, Dr. GEORGE W. POTTER discussed this matter by answering this question, "Is the nursing at the London hospitals sectarian?" Dr. HARE, it may be remembered, justified the exclusive system of nursing by a sisterhood in the University College Hospital by arguing that in most of the other large hospitals the nursing was more or less sectarian, though in only one other is it by a sisterhood. Dr. POTTER contests this representation and adduces tables and facts to show that there is much more freedom than Dr. HARE'S statements implied. He has inquired of sixty hospitals and

Digitized by Google

has received fifty answers, of which the following may be accepted as a summary:—

"1. Those hospitals at which the nursing is undertaken by a religious sisterhood. To this class only three metropolitan hospitals belong. 2. Hospitals having no special religious services of any kind. Of these there are seven. 3. Hospitals at which family prayers are conducted by the matron, or ward-sister, or a nurse—fourteen. 4. Hospitals where services are conducted by an honorary or paid chaplain, who is a clergyman of the Church of England—fifteen. 5. Hospitals where the nurses attend a neighbouring parish church—one. 6. Hospitals where the nurses attend a place of worship of their own choosing—one. 7. Hospitals where prayers are read night and morning by the inmates, and a short service is conducted on Sunday afternoons by a layman—one. This classification accounts for forty-two of the fifty replies given. Of the eight unaccounted for, four may be placed in one or other of these classes, though the replies were received too late for more definite classification. The other four are University College, the German Hospital, the Lock Hospital, and the French Hospital, Leicester-square. The table at the end of the paper gives full information concerning all the fifty."

Dr. POTTER'S tables do not include St. Bartholomew's. But this lack was well supplied in the discussion of the paper by Miss MANSON, the matron of St. Bartholomew's, who spoke on the invitation of Sir ANDREW CLARK. She showed that the nursing of St. Bartholomew's was quite satisfactory, though unsectarian, and that the supply of candidates was far more than the demand. The facts elicited by Dr. POTTER are satisfactory. In all the hospitals but four—the German Hospital, the French Hospital, University College, and the Lock—the nursing appointments are open to suitable persons of all religious denominations. We do not judge those of other nationalities. But our own countrymen who cultivate sectarianism in nursing may well consider whether they serve their hospitals by keeping up an exclusiveness which offends, and without which other institutions are as well nursed as their own. University College Hospital is now almost the only London hospital in which nursing by an exclusive sisterhood remains.

Other speakers took part in the debate. All expressed satisfaction with the fact, demonstrated by Dr. POTTER'S tables, that the rules generally were of an unsectarian character. Mr. NIXON and Mr. HOLMES defended the arrangements of University College Hospital on the ground of their success, and maintained that the question was one of no public importance so long as persons of all creeds were admitted. Dr. GLOVER admitted that the nursing was well done in University College Hospital, but not better than in other hospitals where a different system obtained. He argued that it was of great moment to remove every prejudice against hospitals from the public mind, though he quite believed that the authorities of University College were actuated by consideration for the welfare of the patients. Sir ANDREW CLARK thought much good would result from Dr. POTTER'S inquiries. He deprecated too much "individualism" in estimating the claims and work of hospitals. He admitted the necessity to guard against any appearance of sectarianism, but thought that the least sectarian arrangement in English hospitals was the moderate ascendancy of the services of the English Church.

Annotations.

"Ne quid nimis."

THE DEATH OF DR. AUSTIN FLINT.

IT is with deep regret that we have learnt of the death of America's most distinguished physician, Dr. Austin Flint, which occurred on Saturday last, from cerebral apoplexy. Dr. Flint was so widely known in this country, and so highly esteemed both for his personal qualities and his excellent work, that there will be many on this side of the Atlantic who will join very really in the sorrow of those among whom he has lived and toiled. Dr. Flint was an indefatigable worker. We believe that he commenced practice and lecturing in Buffalo, but promotion soon came to him, and he was called to the Bellevue Hospital and Medical School, where for many years, and up to the time of his death, he was Physician and Professor of Medicine and Clinical Medicine. In both of these capacities he toiled hard and successfully; his class was always crowded, and up to the last he prepared for it most carefully, to keep both himself and his hearers thoroughly abreast of the ever-progressing science and art which he loved. In addition he had a very large private practice, for his great experience, his sound judgment, and his kindly manly nature, made him the chosen consultant of a very wide circle. As a writer Dr. Flint exhibited great diligence. His treatise on the Principles and Practice of Medicine has passed through five editions, and is a worthy memorial of the man. It is a faithful indication of the care with which he set about all his work that, when he had to prepare the last edition, he sought the aid of a special pathologist, Dr. Welch, and committed to him the whole of the sections dealing with pathology. This work has been very popular, and is remarkable for the great amount of information condensed into a comparatively small compass, and for its accuracy. It was in diseases of the chest that Dr. Flint took the greatest interest, and he was the author of a very valuable work founded on the notes of 670 cases of phthisis observed by himself: he also wrote a Manual of Auscultation and Percussion, and published some lectures on the same subject which he delivered in Philadelphia in 1882. He did more than any other physician to develop this department of practical medicine in America, and he never wearied of demonstrating, writing, or lecturing upon his favourite theme. He was an ardent advocate of the binaural stethoscope, but among his choice treasures he kept a simple wooden stethoscope made by Laennec's own hands. Dr. Flint was the President elect of the International Medical Congress, which is to meet next year in Washington. The preparation for such a meeting necessarily devolved much work upon him, and the unfortunate division of opinion, which at one time assumed somewhat alarming proportions and imperilled the success of the Congress, not only increased the work very greatly, but added to it an element of pain, which pressed with crushing weight upon the sympathetic and generous nature of Dr. Flint. His friends cannot but fear that his valued life has been shortened by this strain, and a special bitterness is imparted to their sorrow by the reflection that he has not been permitted to realise his brightest hopes in connexion with the Congress, or to conduct to a successful issue the project in which he took so keen an interest. Dr. Flint was a frequent visitor to Europe, and his handsome presence was well known in London and many of our chief medical centres. He had arranged to deliver the Address in Medicine at the forthcoming meeting of the British Medical Association. As a physician Dr. Flint represented all that is best in the

Digitized by Google

American character, his influence for good was very wide, and his loss is correspondingly severe. But only those who have enjoyed the high privilege of his friendship, and have experienced his unfailing courtesy and generosity and his tender manliness of heart, can rightly appreciate the gap his death causes.

ASSIMILATION OF NITROGEN IN DEBOVE'S "CRAMMING" METHOD.

DR. M. G. KURLOFF of St. Petersburg has published a series of observations undertaken with the view of discovering the chemical changes consequent upon the employment of Debove's "cramming" or "forced feeding" system in phthisical patients. He made six experiments on five patients, who previously to the "cramming" were losing weight, with bad appetites, diarrhœa, pyrexia, and cough, with sputum containing Koch's bacilli. The "cramming" (which in some cases was carried out by means of a stomach tube, as practised by Debove, and in some without, as has been recently recommended by Peiper) lasted for from three to eleven days, during which period careful estimations were made of the nitrogen excreted in the urine and fæces, similar determinations being made during the three days preceding and the three days following the treatment. The quantity and nature of the food were also noted; and from these data and from various analyses of food made on purpose the quantity of nitrogen ingested and excreted was determined and the amount assimilated calculated by subtracting the latter from the former. The material used in the "cramming" process consisted of pulverised meat, from which all the liquid portion had been previously expressed in the manufacture of meat juice, mixed with milk so as to form a drink of somewhat greater consistence than ordinary chocolate. Of this mixture 700 cubic centimetres were given at a time, some 400 grammes of the meat powder being thus introduced into the stomach during the day. It was calculated that this contained as much nitrogen as 3½ lb. of fresh meat. The patients were, however, not confined to the mixture, but were encouraged to supplement it with milk, bread, and biscuits. The mean daily nitrogen ingested was about 54 grammes, which is as much as is contained in 1600 grammes (3½ lb.), the maximum being as much as 80 grammes, corresponding to 2400 grammes (5⅓ lb.) of fresh meat. The effect of this huge quantity of nitrogen was to increase the breaking down of the albuminous constituents of the body, as shown by the increased excretion of nitrogen in the urine, which averaged about 34 grammes, the maximum being 56 grammes, whereas, previous to the "cramming," it had only ranged from 9 to 16 grammes. An increase also occurred in the percentage of ingested nitrogen which was assimilated, and a much more marked increase in the assimilated nitrogen relatively to the body weight. Taking one instance, the percentage assimilation was before, during, and after the "cramming" 84·9, 92·7, and 82·6 respectively, and the mean assimilation, expressed in grammes per kilogramme of body weight, was for the same three periods 0·24, 0·89, and 0·29. Thus during the "cramming" the nitrogen assimilated increased more than threefold, and was slightly more afterwards than previously. Even after the short period during which the treatment was continued, which was undertaken more for experimental than for curative purposes, the patients' appetites increased remarkably: they not only ate the whole of the ordinary hospital ration, but asked for more, though previously they had left a considerable portion of their food. The body weight also increased nearly 1 lb. a day, the increase continuing even after the special feeding was discontinued. Altogether Dr. Kurloff fully confirms the results Dr. Debove and others have obtained by this method of treating consumptives. The cough and expectoration diminished, the diarrhœa and night sweats ceased, and the patients felt a great deal better, so that some of them left the hospital and returned to their respective employments.

KING'S COLLEGE HOSPITAL.

ON Friday, the 12th inst., at the invitation of the Lord Mayor, a meeting was held at the Mansion House in aid of the funds of this hospital. There is an annual deficit of about £5000 over the annual income. Donations and subscriptions have kept up to the average amount, but during the past five years legacies have fallen from £6000 to £1000 a year, and this has necessitated the forced sale of much of the invested capital. It would be a very severe blow to a most important school, associated with names like Todd, Budd, Bowman, Farre, Priestley, and Fergusson in the past—not to mention the present staff—if retrenchment should have to be carried much further, and the beds fall below 150, the limits of the qualifying bodies. At present 170 are in daily occupation, and are filled with absolutely clinical cases, for distress in the Seven Dials and adjoining districts is too severe to permit of any but the most urgent cases being admitted. The claims of the hospital and of the medical school were well put forward by the Duke of Cambridge, the Archbishop of Canterbury, the Bishop of London, Lord Grimthorpe, Messrs. W. H. Smith, Hubbard, Alderman Sir R. N. Fowler, and others, and we would advise the authorities of the hospital to publish their speeches as a special appeal. We cannot doubt that when the charitable public are really aware of the urgent needs of this hospital, the teachers of which are in the front rank of our profession, a cordial response will be accorded, even in these times of severe commercial depression.

THE SHOP HOURS' REGULATION BILL.

A SELECT COMMITTEE of the House of Commons have already met to discuss the clauses of the proposed Shop Hours' Regulation Bill. Notwithstanding some difference of opinion, there seems to be a general agreement on the part of the promoters of the Bill, as well as of employers and employed, to whom it is intended to apply, that this measure is called for, and that it can best be carried out by definitely fixing a closing hour. A general allotment of twelve hours daily as working time, it is said, would prove a less satisfactory arrangement. There is also a strong desire on the part of tradesmen that on Saturdays and market-days late hours should continue to be the rule, as much business is done in the evening on these days. The evidence of Mr. Redgrave, chief inspector of factories, on this subject is instructive. Besides supporting the propositions to which we have referred, he is further of opinion that licensed houses and refreshment-rooms (as under the Factories Acts), and also the shops of butchers, bakers and chemists, should be excepted from the proposed new legislation. The poor, he maintains, have some advantage in the cost of food by shopping late. We should be sorry to lessen their profit in this particular; at the same time, the interests of assistants must also be considered; and there seems to be much force in the suggestion made by Mr. Fry, that to leave licensed houses open long after other shops had closed might almost amount to an advertisement in favour of the former. The cry that restriction of time would hurt the interests of junior assistants, since only persons under eighteen years of age are to be affected by it, has not, according to Mr. Redgrave, been justified by events in the case of factories and workshops. We are pleased to find that the same gentleman is in favour of some form of official inspection. We have always inclined to the belief that with this, as with any

Digitized by Google

other enactment bearing on the conduct of trade, inspection is a logical and needful part of the legal process, and that it should not imply an offensive closeness of supervision. The fact that shopkeepers generally hail the expected regulation of their business hours may in itself, we think, indicate a readiness on their part to accept a certain degree of official oversight. Wholesale houses, it is to be noted, do not take kindly to the present wording of the Bill. They complain that their work is very irregular in its duration from day to day, and varies between the wide limits of nine and fifteen hours in the twenty-four, and they would therefore prefer a weekly or monthly rather than a daily regulation. They prophesy dismissal of apprentices and damage to trade should the Bill become law. On the other hand, a letter lately published informs us that the figures above stated do not, in one such house at least, represent the true state of matters. There the assistants work during slack times for twelve hours daily, and in the busy season for fourteen or fifteen. It does not, therefore, seem very clear that wholesale houses deserve the discretionary power as to daily working time which they seek. If we look at the Bill as a whole, we cannot but feel, while admitting its value, that it goes hardly far enough. Thus there seems no good reason why adults as well as youths should not be included within its range. Overtime work may sometimes be allowable for such, but if so, it should not on that ground be considered as acquitted from possible restriction, otherwise the exception may become the rule, and adults have to make good the leisure granted to their juniors. We miss also some arrangement which will concede to shopmen the weekly half holiday now common in many callings. If we turn again to the proposed exceptions, there seems no great necessity for most of them. Let refreshment bars at places of entertainment be allowed to close late, and enough will probably have been done for public convenience. Because a shop is closed it need not follow that it is barred against emergencies. The messenger of an invalid, for example, may be served by a chemist even after he has retired for the night, but in order to meet such urgent cases it is not necessary to attract custom of every kind by keeping open shop. For these various reasons we would hope that further evidence may assist the committee in framing a measure somewhat wider even than that which now lies before them.

THE UNDOING OF A DEED OF GOODNESS.

THE pity of it! After opening up a way of return and providing a place of repentance for the most pitiable lost class of our great mixed community, and extending the blessings of the healing art to those who have perhaps the very least claims on the sympathy and help of their fellows, a rampant spirit of that self-righteousness which affects to find an excuse for refusing to do good lest evil should come has succeeded in undoing all that mercy has achieved. The crazy and fatuous agitators against the Contagious Diseases Acts have clamoured at the office doors of a weak Government and profited by the impressibility of a sentimental majority in a scratch House of Commons. Henceforward, forsooth, that we may not run the risk of seeming to countenance vice by dealing kindly with the vicious, disease and immorality in their most revolting forms are to riot in the midst of our army, navy, and the civil population of garrison towns! When will the weak-minded sentimentalists of this nineteenth century cease to worry the life out of humanity with their whimperings? It is too late to treat this subject as involving a question for serious argument. It has been conclusively demonstrated that the Contagious Diseases Acts were of marked value to the interest of health and morals. It remains only to bemoan the fatuity which has allowed them to be set aside.

M. JULES VERNE.

THE many admirers of M. Jules Verne were distressed to hear last week that he had been attacked by his nephew, and had received a serious bullet wound of the leg. The ball has buried itself in the tibia, and we learn that a prolonged but unsuccessful attempt to remove it has been made, and that the wound has been left open in the hope that the ball may be spontaneously discharged. Probably in this there is some error. It is a common popular notion that the safe extraction of a bullet removes the chief danger of a gunshot injury. This is, of course, not the case. The main element of danger arises from the injury inflicted by the bullet in its path through the tissues, injuries which are only rarely benefited by the extraction of the offending missile. Then follow secondary, and scarcely less formidable, perils arising from inflammation in the track of the ball, occasioned in part perhaps by the direct injury of the tissues, but to a much greater extent by irritating and poisonous materials finding access to the wound or generated therein. The removal of the bullet does not directly lessen the danger from this source. Still the extraction of a ball is important; it is often essential to the proper treatment of the deeper parts of the wound; and even when no acute mischief follows the injury the mere presence of the ball may cause such a degree of chronic inflammation as will prevent the closure of the wound. The two cases of bullets long imprisoned in the lower end of the femur which were lately recorded in our columns by Sir W. Mac Cormac aptly illustrate this, and the excellent results which followed extraction in those cases will, we hope, be attained in the case of M. Jules Verne. For we hope soon to hear that he has submitted to a second and successful operation.

LOCAL DISTRIBUTION OF SUICIDE IN ENGLAND AND WALES.

IN the discussion that followed the reading of Dr. Ogle's recent paper on "Suicides in England and Wales" before the Statistical Society, it was pointed out that the local distribution of suicide was a subject not devoid of interest, although this branch of the subject was not dealt with in the paper under discussion. Dr. Ogle, in his reply, called attention to the difficulty of obtaining a sufficient basis of facts to yield figures trustworthy for comparative purposes for such populations as inhabited many of the English counties. Whilst fully admitting the validity of this objection to suicide-rates for small populations, some available figures may be referred to which are useful in throwing light upon the varying death-rates from suicide in different parts of England and Wales. It appears from the Decennial Supplement recently issued by the Registrar-General that the annual death-rate from suicide in the ten years 1871-80, which was equal to 71 per 1,000,000 persons living in England, did not exceed 41 in Wales. With reference to this low rate from suicide in Wales, it may be pointed out that in Cornwall, where the population shows affinities in race to that of Wales, the suicide-rate was almost identically the same, 40 per 1,000,000. On the other hand, the rates in the counties on the borders of Scotland exceeded the general English rate. Apart from the low suicide-rates prevailing in Wales and in Cornwall, it would appear that the death-rate from this cause is governed to a large extent by the proportion of the urban element in the population. In the eleven registration divisions the rate from suicide in the ten years 1871-80, without correction for differences of age and sex distribution, was highest, 85 per 1,000,000, in London, and 81 per 1,000,000 in the south-eastern division, containing the counties of Surrey, Kent, and Sussex, which contain a large proportion of the metropolitan suburban population. The high rate in Sussex is mainly due to the exceptionally

Digitized by Google

large proportion of suicides in Brighton, Hastings, and other seaside holiday resorts, which are practically seaside suburbs of London. The next highest rate from suicide in the registration divisions prevails in the north-western division, consisting of the counties of Lancashire and Cheshire, which next to London includes the largest proportion of urban population. At the other end of the scale are the Welsh and the south-western registration divisions, with suicide-rates of 41 and 58 per 1,000,000 respectively. Whether the low rate in Wales be due to race characteristics, or to the fact that the population of the greater part of the principality is mainly rural, further investigation would alone determine, although the facts now available decidedly point to the more marked influence of race upon the suicide-rate. The south-western division contains the counties of Wiltshire, Dorsetshire, Devonshire, Cornwall, and Somersetshire; and although the rate from suicide was only 50 in Dorsetshire, 51 in Wiltshire, and, as has before been stated, 40 in Cornwall, it was 65 in Somersetshire and 69 in Devonshire, the two latter counties containing larger proportions of urban population. It should be pointed out, however, that in several essentially rural counties the rate from suicide was scarcely below, while in some it was above, the general average; for instance, the rate was 69 in Norfolk, and 81 in Suffolk and in Lincolnshire. One of the most remarkable exceptions, however, to the usual relation between the proportion of the urban element in the population is the county of Durham, where the rate from suicide was only 49. This low suicide-rate in Durham appears to be due to the fact that miners show, in comparison with other occupations, a most remarkable freedom from suicidal tendency.

SNAKE-POISON AND HYDROPHOBIA.

MEDICINE is one of those subjects about which it is never safe to predicate any absolute statement. Anyone may make an assertion in medicine which at first sight appears to be as preposterous as anything can well be; and yet the nature of medicine is such that second thoughts may render the assertion not altogether so absurd as at first appeared. Some correspondence has been in progress in our columns on the alleged antidotal effects of snake-poison and the virus of rabies. In the month of January Dr. G. C. Roy contributed an original article to THE LANCET, in which he contrasted the physiological actions of snake-poison and the symptoms of rabies, and suggested that the venom of the cobra should be employed to counteract the morbid phenomena of rabies. The suggestion is by no means an original one. But it is not the claim of originality that subsequent correspondents—chief amongst whom is Mr. Vincent Richards—have so much interested themselves. The matter appears to them in a somewhat ridiculous light. Confessedly the suggestion cannot be said to rest on any scientific basis, for even the physiological contrast instituted by Dr. Roy hardly lends support to his well-meant proposal. A valuable small work by Mr. Vincent Richards, entitled "The Landmarks of Snake-poison Literature," collects together a large number of facts concerning snake-poisons,[1] and reviews the more important researches into their nature. To those who wish in the compass of 150 pages to become acquainted with the anecdotes, fallacies, opinions, original researches, mode of treatment, and in fact every phase of snake-poisoning, we heartily commend this little book; it is written in a cheerful vein, albeit it is occasionally warlike and severe in its method of dealing with opposite views. It is far better, in the interest of everybody and everything, that the truth should be plainly told. We have no antidote to snake-poison when once this has fully entered the system. If the venom can be confined to a part by means of a ligature, then permanganate of potash in a 5 per cent. solution is an efficient destroyer of its power. Halford's advocacy of ammonia in the treatment of snake-bite is conclusively shown to be a fallacy. Fontana in the last century had also discovered the inefficacy of ammonia. The truth appears to be that if an insufficient dose of the venom be administered, the animal lives whether stimulants, alcohol, or ammonia be given or not. Mr. Richards goes further than this, and shows experimentally that ammonia, if anything, increases the rapidity of action of a fatal dose. In the controversy at Melbourne doubt seemed to exist amongst some as to the symptoms of snake-poisoning. Mr. Richards asserted that in the cases of recovery from snake-bite the symptoms observed were the effects of alcohol administered in large doses. That the intellect in snake-poisoning remains unclouded to the last is the testimony of the most competent observers. The physiological researches of Weir Mitchell, Reichert, and Wolffenden are justly esteemed as of the highest value, whilst at the same time forming a new departure in our knowledge concerning the nature of powerful poisons. Snake-poison, from the cobra at all events, contains three kinds of albumen—a proteid, a globulin, and a peptone. Differences still exist as to the precise chemistry, but the globulin appears to be the most powerful poison, and acts by paralysing the respiratory centre of the medulla.

[1] Calcutta: D. M. Traill, British Indian-street. 1885.

THE EAST WIND.

THAT the "east wind" has from the earliest times been credited with evil influence is apparent in the fact that Ephraim was described in one of the most ancient of the Jewish traditions as feeding upon it. What a repast! Modern science has determined that what we call the east wind is really a current of air from the north, its direction being modified by the rotatory movement of the earth. This is not difficult to understand. The avidity with which the dry cold wind from the north takes moisture, and particularly the secretion of the mucous membrane lining the air-passages, inspissating the mucus, and, as it were, gluing together the cilia of the epithelium, is the real cause of the malignancy of the "east wind." We have repeatedly explained this fact, and pointed to the use of a succulent jujube or something which will give off moisture in the mouth to be carried into the air-passages with the inspired air as the best of practicable measures of protection. We believe that if only the habit of keeping a morsel that gives off aqueous vapour—not one that dissolves by taking up moisture—in the mouth during the time of exposure to the east wind were formed, there would be very few colds from that cause.

"MEMORY, NATURAL AND ARTIFICIAL."

WE have received an interesting little pamphlet on "Memory, Natural and Artificial," by Mr. F. W. Edridge Green. The paper was originally read before the Abernethian Society in St. Bartholomew's Hospital. It treats in a suggestive manner of the nervous action concerned in the repetition of muscular movements, and of sensory impressions, as due to the development of a function akin to intellectual memory in the corpus striatum and optic thalamus respectively. Reflex automatism in which the basal ganglia participate is fairly regarded as an expression of the completed stage of this form of memory. Passing on to the higher manifestations of the same faculty in its relation to mental operations, Mr. Green finds, in common with other observers, that decisive localisation is as yet an unaccomplished possibility. He quotes numerous cases of loss or excellence of special forms of memory, however, which may hold out a dim prophecy of greater exactness

Digitized by Google

in the future map of cerebral structure with regard to function. The paper closes with some valuable hints on the cultivation of memory. These are briefly given as follows:—"Concentrate your attention, classify and condense, make associations, substitute letters for figures, and localise your ideas."

THE EDINBURGH MEDICAL MISSIONARY SOCIETY.

WE have read the annual report—the forty-second—of this Society with much gratification. We have the conviction—very beautifully expressed by the late Professor Alison of Edinburgh, in an essay on medical missions—that the science and art of medicine are to be greatly used by Christian men in their efforts to extend Christianity and civilisation among the less favoured nations of the earth. This conviction is confirmed by every report of the work done by medical missions, whether in China, India, or Africa. Of all missionary societies having claims on medical men or on the public, none has stronger claims than the Edinburgh Medical Missionary Society, as the oldest one of the kind, and the most efficient. It has a training school for medical missionaries, in which students learn the nature of medical missionary work among the poor. It has mission stations in India, Nazareth, and Damascus. The institution in Agra incorporated with this Society serves as a training school for native medical missionaries, who, by the kindness of Sir William Muir when Lieutenant-Governor of the North-West Provinces of India, receive their medical education free at the Government Medical College. The encouragement of the medical education of natives is evidently one great means by which we can confer enormous benefits on Eastern nations. A kind friend of medical missions has offered to bear one half of the expense for three years of establishing a Christian medical school in Japan, where the Government now gives licences to practise only to those who pass an examination in Western science. The Edinburgh Medical Missionary Society is not connected with any one Church, but supplies legally qualified missionaries to the various missionary societies. It is a great credit to the Edinburgh school, which may have its parties and even its differences, but has, too, its practical Christianity, which is felt through this Society in every part of the world.

DEATH FROM ETHER, OR NOT?

WILL some of our older surgeons tell us the frequency with which death occurred in ante-anæsthetic days, just before the operation began, from the shock of fear added to the exhaustion produced by previous agony. A case—that of Mr. George Harling, of Lockwood, near Leeds—has just occurred, in which a patient suffering from cancerous obstruction of the bowels and peritonitis begged for the only operation that could give any relief—that of colotomy,—though Mr. Teale expressed his opinion that it could only be of temporary benefit. In deference to the importunity of the patient the operation was about to be performed. He had not taken more than three or four inhalations of ether when he threw himself back, breathed once or twice, the pulse suddenly ceased, and the patient died. Mr. Hall, the practitioner in attendance, gave it as his opinion that the death was not caused by ether. At the post-mortem, besides the appearances of peritonitis and malignant disease, a fibrinous clot was found in the right ventricle attached to the tricuspid valve. The jury returned a verdict of "Death from natural causes." We concur fully in the justice of this verdict. Possibly the slight agitation incident to the operation and the administration of the ether, with a fibrinous clot already in the heart, might contribute to the fatal issue, which could not, however, have been deferred many hours.

PROPOSED AMALGAMATION OF THE SANITARY INSTITUTE AND THE PARKES MUSEUM.

THE Councils of the Sanitary Institute of Great Britain and the Parkes Museum have mutually agreed to a proposal to amalgamate and reconstitute the two institutions into a new body, to be incorporated by a Royal Charter under the title of the Sanitary Institute and Parkes Museum. The matter is now in the hands of the Fellows, Members, and Associates of the respective institutions. A decision will probably be definitely arrived at on March 25th. It is pointed out that the aims and scope of the two Societies are in many respects the same, though each possesses functions peculiar to itself, but which might, the Councils think, with advantage be shared by both. The institutions were each started exactly ten years ago; they already possess one and the same secretary and place of abode, and their respective numbers of members are pretty much alike. It is urged that by amalgamation the prosperity as well as the utility of the Societies would be largely promoted. If the union is definitely decided upon, an application will be made to the proper quarters for a Royal Charter to found the new institution.

THE POISONS ACT.

WE understand that it is the intention of the Government to propose a revision of the regulations affecting the sale of poisons. It is generally admitted that the Act as at present administered is unsatisfactory, inasmuch as the list of articles included in the Schedule of Poisons is singularly incomplete, whilst the formalities connected with the retailing of certain popular poisons, which it would be superfluous to name, are practically inoperative. The question of including nitro-glycerine in the list of prohibited articles has for some time past occupied the attention of the Crown. It is universally recognised that it is a most valuable medicinal agent, but it must be admitted that its introduction into the British Pharmacopœia in the form of a sweetmeat was an egregious blunder. Either the 1 per cent. alcoholic solution, which is in constant use by medical men, will have to be substituted for the objectionable and dangerous chocolate drop now so commonly advertised as a popular remedy for neuralgia and sea-sickness, or its indiscriminate sale to the general public will have to be restricted. The other articles proposed to be added to the list are lobelia, nitro-benzol, savin, and their preparations, together with the soluble oxalates. It is a remarkable fact, in view of certain recent legal proceedings, that chloroform is not mentioned. On the other hand, the frequent fatalities following the unrestricted use of carbolic acid as a disinfectant have not escaped notice, and the necessity for including it in the second part of the schedule is again being forced on the attention of the Privy Council.

THE PARENTAL "DON'T."

SOME parents are continually checking their children. Others, again, seem to have hardly will enough to chide or deny them anything. A little work which has reached us, and which bears the above title, seeks to instruct fathers and mothers how to steer a middle course between these difficulties and to ensure a successful future to their offspring. Success, in the words of the author, implies more than financial distinction. There must be true and equal development of the physical, mental, moral, spiritual, and commercial side of life in order to deserve the term. His advice to this purpose is on the whole very sensible, and is given in a terse but interesting style, which renders the paper agreeably readable as well as instructive. We note with satisfaction that he dissents from the present high-pressure

Digitized by Google

system of school education, and would rather train the mind of childhood than fill it. Physical exercise receives due attention. Practical hints on the teaching of morals and religion are not wanting. A somewhat lengthy section is devoted to home hygiene and the rearing of infants. The observations contained in this chapter are well considered and accurate. We could wish that all parents were equally clear in their understanding of the value of milk alone as an article of infant diet, on the injurious effects of close, hot rooms, long and heavy clothing, empirical sedative remedies, overcrowding, and drainage deficiencies. We do not doubt that readers of this pamphlet will learn from it some points of use in the training of children which they don't know at present.

THE LATE PROFESSOR MARCOVICI.

THE Roumanian medical journal, *Spitalul*, announces the death, at the age of fifty, of Dr. Al. Marcovici, Professor of Clinical Medicine and Dermatology in the Faculty of Medicine of Bucharest. The deceased professor received his early education in various schools in Roumania, whence he went in 1853 to Paris, where he took the degree of Bachelor of Science two years later. He then entered as a medical student, and distinguished himself by gaining medals and by obtaining a post as interne in the Bicêtre. He worked under Sée, Robin, and Grisolle, and greatly distinguished himself in his thesis for the doctorate, which was on the different kinds of pleuritic effusions and their medical and surgical treatment. He afterwards returned to his own country, where he was appointed professor in the University of Bucharest. He wrote various works and papers on Quinine in Malaria, Acute Granular Phthisis, Diabetes, Cholera, &c. He also took part in several important international medical congresses, where he represented his country, in those of Brussels and Amsterdam being nominated honorary president. He was also present in a representative capacity in the congress held in London in 1881.

DR. CLOUSTON ON CHANGES IN THE FORM OF INSANITY.

DR. CLOUSTON advances some opinion on the variations of type in mental disease which, while admitting the authority of his opinion, we are not disposed to accept without further evidence. They are the views of an able superintendent of an asylum, but they cannot, in the nature of things, express the result of more than a limited series of observations. We think Dr. Clouston lays too much stress on alcoholism as a cause of insanity, and we venture to doubt whether general paralysis is actually decreasing. On the contrary, it seems to be more common than heretofore. The recognition of "mental disease," so-called, in the aged is very much an affair of economic policy even in Scotland.

MEDICAL HEROISM IN RUSSIA.

A CASE of heroic self-sacrifice of medical men has just occurred at Kharkoff. A patient was brought into the lunatic asylum with hydrophobia, who was so violent that he had to be put into a sack and carried along by gens d'armes. All the attendants refused to touch the unfortunate man, declaring that they would rather lose their situations; thereupon two of the medical officers, Drs. Gutnikoff and Davidoff, themselves undertook to wash him and attend to him, though he was in the filthiest condition and covered with vermin. They managed after some time to get him somewhat cleaner and calmer. However, in one of his paroxysms, he bit Dr. Gutnikoff in the finger, and bespattered Dr. Davidoff's hand and eye with his saliva. The man did not live through the night. The two doctors are considered to be in great danger, and the principal, Professor Kovlefski, has written to Pasteur about them. It seems, however, that they have no funds to enable them to undertake such a long and expensive journey. Perhaps, however, public or private generosity may step in, or, as they are Government officials, it is conceivable that the Imperial treasury may be opened for the purpose.

HEALTH OF THE PRINCESS OF WALES.

WE have authority for stating that the health of her Royal Highness the Princess of Wales is not such as to cause anxiety. After her Royal Highness's late illness at Sandringham, Torquay was proposed for change and fine air at this season. The Princess has lately had a common cold, which, together with the inclemency of the weather, has prevented the usual carriage exercise.

AMPUTATION OF THE THIGH UNDER COCAINE.

DR. VARICK of New Jersey records in the *New York Medical Journal* of Feb. 20th a case in which he employed cocaine as a local anæsthetic for amputation of the thigh. The patient was a man aged thirty-nine, who was admitted to hospital with a compound fracture of the leg. An attempt to administer ether caused such alarming symptoms that it had to be abandoned, and Dr. Corning was requested to employ his method of confined injections of weak cocaine solutions while the limb was removed above the knee-joint. The result is stated to have been most successful; the division of the skin and deeper soft parts occasioned no pain, but during the sawing of the bone the man complained loudly of pain. A solution of 1 per cent. was used for the skin, and a solution of half this strength for the deeper parts: the report does not state the exact amount of the solutions that was injected. Such a case as this shows us that in cocaine we have a local anæsthetic of extreme value, and which, under certain circumstances, can successfully replace general anæsthesia even in the gravest surgical operations.

MERCURIAL DISINFECTION OF ROOMS.

PROFESSOR ROUIG recommends that in epidemics of cholera, typhoid, small-pox, &c., the chambers which have been occupied by the patients should be disinfected by means of fumes of corrosive sublimate in the following manner. The room is closed and a vessel of live coals placed in the middle. Upon this fire about two ounces of sublimate are thrown, and the room is not opened for three or four hours. The most careful covering up of mouth and nose is necessary on entering to open the windows. After free ventilation has been continued for several hours, the remaining traces of mercury may be rendered innocuous by fumigating with sulphur.

CHOLERA IN BRISTOL IN 1835.

IT will be remembered that during the past year it was alleged that a case of cholera found its way into Bristol. We have Mr. Davies's annual report for 1885 now before us, and it supplies us with authentic details as to the occurrence. A sailor from on board a vessel infected with cholera in Marseilles harbour travelled direct to Bristol and died there very soon after his arrival, the coroner's jury finding that he died of symptoms resembling those of Asiatic cholera. Mr. Davies, whose experience of cholera in a former epidemic enables him to speak with very considerable authority on the subject, expresses his firm conviction that the disease of which this man died was "true Asiatic cholera" contracted at Marseilles, and, so far as preventive measures are concerned, he acted according to this conviction. The body was covered with disinfectants and imme-

Digitized by Google

diately buried, articles that could have become infected were destroyed, and possible pollution of the local well-water was dealt with by removing the handle of the pump which was in the room where the corpse lay. The incident supplies two lessons:—Firstly, the uselessness of the quarantine measures resorted to by the French authorities at Marseilles in preventing the diffusion of cholera by human intercourse; and secondly, the immense advantage of trust in sanitary measures such as have for years past been in progress in what was formerly a cholera locality, and of the immediate adoption of measures of sanitary precaution, which cannot be secured in a moment of panic, but which are the natural outcome of a properly organised system of sanitary organisation.

THE LATE DR. ALFRED C. POST OF NEW YORK.

THERE is a wonderful harmony in the tribute paid by all the New York medical papers to the late Dr. Alfred C. Post, who died at the ripe age of eighty-one, but who was expected to have lived and worked much longer, and would have done so but for a sudden and sharp sickness. He had performed a very successful ovariotomy only four months before his death. He was the nephew of the celebrated Dr. Wright Post, the friend of Percival Pott, Cooper, Abernethy, &c., and the father of Dr. George E. Post, the able surgeon and devoted missionary of Beirut. He was happy, too, in his early education, in which piety and culture were combined. He was a good classical scholar, but his chief delights were in religion and surgery, and he once said, in no irreverent spirit, that the two things he enjoyed most were a surgical operation and a prayer meeting. Dr. Post of Beirut was in London last summer. Eager to be back at his Syrian work, and assured of his father's health, whom he had not seen for eighteen years, he resolved to defer the pleasure of visiting him to another year. The father has been translated sooner than either expected, but in the exercise of the same beneficent art and with the same religious spirit Dr. Post will find consolation.

NERVOUS SEQUELÆ OF SMALL-POX.

WE would draw special attention to the interesting paper contributed by Drs. Whipham and Myers to the last meeting of the Clinical Society. The interest of the subject lies simply in the fact of the occurrence of disorders of articulation after the small-pox has disappeared. Small-pox, like other acute specific fevers, is liable to be followed by various nervous sequelæ, either of cerebral, spinal, or peripheral origin. Dr. Barlow and Dr. S. Mackenzie contributed some interesting cases occurring after small-pox and during measles. We have much yet to learn concerning the disorder of articulation of which living specimens were exhibited the other night. Dr. Hughlings Jackson was inclined to locate the lesion in the medulla oblongata, and to regard its nature as of thrombotic order. However, at present there is but little to be said that is definite.

SUBJECTS FOR DISSECTION IN RUSSIA.

DIFFICULTIES are frequently experienced by medical schools in this country in obtaining sufficient subjects for dissection, and we are apt to envy continental schools which appear to us always to enjoy a profusion. This is not, however, invariably the case. The University of Dorpat is at present considerably agitated by an order which has been made stopping the supply which had hitherto been obtained from the hospitals and prisons of St. Petersburg. Subjects from these sources are in future to be monopolised by the Military Medical Academy of St. Petersburg, and as the towns in the Baltic provinces where Dorpat is situated are of very moderate dimensions, considerable difficulty will be experienced in satisfying the needs of the constantly increasing number of students.

AMENDMENT OF THE MEDICAL ACT.

IT is announced in the middle of an almost unprecedented political crisis that a Medical Bill will be introduced. Of course, whenever such a Bill appears, it will receive from us fair and even favourable consideration. In the meantime it seems to us scarcely credible that any Bill can be passed just now pretending to meet the recommendations of the Royal Commission or the reasonable wishes of the profession.

PROFESSOR TYNDALL.

SIR WILLIAM GULL informs us that Professor Tyndall has for a long time suffered from sleeplessness, which at length, with hard scientific work, has much prostrated the nervous system. It is to be hoped that he will now take a long rest, which is so much needed for his restoration.

THE SUNDAY CLOSING BILL.

WE regret the miscarriage of this measure. No one who has medical knowledge can doubt that a great curtailment of drinking and the hours for drinking would be for the advantage of this country, and that work on Monday would be infinitely better resumed if there were less drinking on Saturday nights and Sundays. The Bill has the support of the people, but the forms of Parliament are capable of abuse, and of enabling it to prevent good being done.

REFORM OF THE UNIVERSITIES OF SCOTLAND.

NINE HUNDRED of the graduates and members of the Council of the University of Glasgow have memorialised the Secretary of State for Scotland in favour of amending the constitution of the Universities of Scotland, so as to give more power to the general body of graduates, and to break down the monopoly of university teaching. There is much to be said for careful changes in this direction.

A NEW ELEMENT: GERMANIUM.

MR. CLEMENS WINKLER writes to the Chemical Society from Freiburg, Saxony, under date Feb. 21st, that he has discovered in the mineral argyrodite a non-metallic element closely related to arsenic and antimony, and that he has named it germanium. Argyrodite is a new mineral discovered at Freiburg by A. Weisbach, consisting of silver, sulphur, and germanium.

FOREIGN MEDICAL APPOINTMENTS.

DR. A. BOICESU has been appointed to the Professorship of Zoology, and Dr. Maldarescu to that of Clinical Medicine, in the University of Bucharest; also Dr. Rizu to the Chair of Therapeutics in the other Roumanian University, Jassy. Dr. L. Turnas, of St. Petersburg, has been appointed Professor of Pharmacology in Warsaw. Dr. G. Albertotti has been appointed Professor of Ophthalmology in Modena.

THE Museum and Lecture-rooms Syndicate of the University of Cambridge have issued a report containing earnest appeals from Professor Foster and his assistant lecturers for more space, which is sadly needed for the proper teaching of physiology. The plans already approved for the new buildings provide for more accommodation for the physiologists, but they are not yet taken in hand, and the object of the report is to hasten their commencement.

Digitized by Google

THE late Mrs. Curwen, who recently died at Brighton, has left, in the event of her daughter dying without issue, £40,000 to St. George's Hospital, on condition that one of the wards be named the Ewing Ward, and that the money be kept as a separate fund. The testatrix also bequeaths £5000 each to the Great Northern Hospital, St. Mary's Hospital, and All Saints' Seaside Convalescent Hospital, Eastbourne; £2500 each to Westminster Hospital, Charing-cross Hospital, the London Fever Hospital, the Royal Free Hospital, the London Hospital, the Cancer Hospital, Middlesex Hospital, Queen Charlotte Lying-in Hospital, the General Lying-in Hospital, the City of London Lying-in Hospital, the National Hospital for the Paralysed and Epileptic, the Royal Westminster Ophthalmic Hospital, the Hospital for Sick Children, Great Ormond-street, and the North-Eastern Hospital for Children, Hackney-road; and £500 each to the Victoria Hospital for Children, and the Belgrave Hospital for Children.

WE regret to learn of the serious illness, from pneumonia, of Dr. Imlach. The Medical Institution have resolved to postpone their meeting for the discussion of certain letters on the action of the Society in regard to the frequent performance of laparotomy. Whatever may be thought of this operation and of the circumstances calling for its performance, there can be but one opinion as to the propriety of the resolution of the Medical Institution. We sincerely trust that Dr. Imlach's recovery will be prompt and complete, for his own sake and for the sake of a right judgment on this important question in surgery. The profession will certainly feel that the proper thing is to suspend judgment.

A MEETING of the Governors of Wellington College was held at Marlborough House on Monday, the 15th inst., with the Prince of Wales as President. It is to be hoped that, among other matters, the present condition of the health of the boys was considered, owing to the number excluded from classes through illness. We have before called attention to grave and preventable illness among the boys, masters, and servants in the past, and again direct attention to the necessity for a full and impartial inquiry into the sanitary state of the institution.

THE number of physicians in Germany averages 1 to 3025 inhabitants. Their distribution, however, is very uneven, the cities and watering-places being especially well supplied. In Bonn there is 1 medical man to 440 inhabitants, in Weisbaden 1 to 558, in Berlin 1 to 1063.

SOME of the proprietors and licensees of houses for the reception of lunatics are not satisfied with the Lunacy Acts Amendment Bill of the Lord Chancellor, and have petitioned that the measure may be referred to a Select Committee, where they may be heard by counsel.

THE Prince of Oldenburg, Commander of the Russian Imperial Guards, intends to found an establishment at St. Petersburg for the treatment of hydrophobia by inoculation, and preliminary experiments are now being made.

DR. HERBERT TYRRELL GRIFFITHS, Medical Registrar of St. George's Hospital, was on the 12th inst. appointed Visiting Physician to the Seamen's Hospital, Greenwich, vice Dr. Carrington, resigned.

A REMARKABLE case of total ablation of the arm and scapula, followed by recovery, is fully reported in the *Journal de Médecine de Bordeaux* by Dr. Loumeau.

ELEVEN cases of cholera, seven of them terminating fatally, are reported to have occurred in the neighbourhood of Padua, and three cases, resulting in two deaths, near Rovigno, in Istria. Elaborate quarantine precautions are to be taken previous to the landing at Toulon of the French troops from Tonquin.

PROFESSOR VON FRISCH, of Vienna, a pupil of Dr. Koch, has been appointed to go to Paris and study M. Pasteur's system, at the expense of the committee which has been formed in that city to found an institution for the cure of rabies.

AT a meeting of the Senatus of Aberdeen University, on the 6th inst., the degree of LL.D. was conferred upon Patrick Manson, M.D., Hong-Kong, China, and Sir Samuel Rowe, M.B., C.M. Aberd., K.C.M.G., Governor-General of Sierra Leone.

A NEW publication devoted to the subject of pharmacy has been published at Melbourne, entitled the *Australian Journal of Pharmacy*.

ON the 16th inst. the French Academy of Medicine voted 10,000 francs to the Pasteur Institution.

DR. GERVIS has been appointed Consulting Physician to the Royal Maternity Charity.

THE CEREMONY ON THE EMBANKMENT.

ON Wednesday next, the 24th inst., Her Majesty the Queen, as already announced, will graciously lay the foundation-stone of the Examination Hall to be erected by the Royal Colleges of Physicians and Surgeons conjointly on the Thames Embankment. The site chosen, which belongs to the Duchy of Lancaster, is situated just to the west of Waterloo-bridge, between Savoy-street and Savoy-hill. The building, which will be square in form, has a frontage of 150 ft., and will, including the basement, contain five floors. The ground floor will be occupied by clerks' offices, the smaller examination-rooms, and private rooms for the examiners. The first and second floors will be identical, each comprising a large examination-room 100 ft. by 30 ft., capable of division into two apartments should this be necessary, and two rooms, one at either end, measuring 60 ft. by 21 ft. An apartment for chemical examinations will be provided on the third or top storey, with every requirement for technical work, and here also will be found rooms for anatomical and various purposes. With regard to the exterior, the main front will be in Savoy-place, overlooking the Thames. There will be three entrances, from Savoy-place, Savoy-street, and Savoy-hill, each being furnished with staircases leading up to the top storey. The materials used in the façades are to be principally red brick and Portland stone, and the style will be Italian. Mr. Stephen Salter, of Woburn-place, is the architect, and Messrs. Higgs and Hill the contractors. Although the space at the disposal of the authorities is necessarily extremely limited, we are glad to see that every possible effort has been made to accommodate all grades of diplomás of the two Colleges. The College of Surgeons, owing to the great number of its Fellows and Members, has had to have recourse to the "hazard of the die," the number of available tickets having been divided between the two Colleges. The College of Physicians has thus allotted their share—viz., Fellows 140, Members 130, and Licentiates (taken we believe in order of seniority) 200. We are gratified to see that the suggestion we made last week with regard to the latter has been thus liberally responded to. The result of

Digitized by Google

drawing lots at the College of Surgeons will probably give room, over and above those holding office in the College, for about 260 Fellows and 130 Members. The deans of the medical schools of the eleven metropolitan hospitals have been asked to nominate a member of each of their schools to act as a steward on the occasion. A guard of honour will be formed by the Volunteer Medical Staff Corps and the field officers' guard of the Artists' Volunteer Corps (mainly consisting of medical students). Considering the small space at their disposal, the authorities must be congratulated on their excellent endeavours to accommodate all who have a just claim to be present on an occasion which will ever be a memorable one in the history of British medicine. We append the programme of the details of the ceremony.

PROGRAMME.

All visitors are requested to be in their places by 12 o'clock.

The band of the Scots Guards will play a selection of music at intervals until Her Majesty the Queen arrives.

At 12.15, the President and the two Vice-Presidents of the Royal College of Surgeons of England and their officials will enter in the following order:

An Usher with the College Staff.

The Assistant-Secretary, Frederic Greville Hallett, Esq., bearing the Charter and Bye-laws of the College.

The four Senior Members of Council:

Sir James Paget, Bart., F.R.C.S., D.C.L. Oxon., LL.D. Cant.
Sir T. Spencer Wells, Bart., F.R.C.S., F.K.Q.C.P. Ireland.
John Marshall, Esq., F.R.C.S., F.R.S., LL.D.
Edward Lund. Esq., F.R.C.S.

The Secretary, Edward Trimmer, Esq., M.A., bearing the College Seal.

The Conservator of the Hunterian Museum:
Professor Charles Stewart.

The Porter, carrying the Mace.

The President of the Royal College of Surgeons of England—William Scovell Savory, Esq., M.B. Lond., F.R.C.S., F.R.S.

The Senior Vice-President—John Wood, Esq., F.R.C.S., F.R.S.

The Junior Vice-President—Henry Power, Esq., M.B. Lond., F.R.C.S.

Their Insignia of Office having been deposited on a table prepared for them, the President and the two Vice-Presidents will take their appointed places in the arena, and the others will retire to their seats.

At 12.20 the President and the two Vice-Presidents of the Royal College of Physicians of London and their officials will enter in the following order:

The Porter of the College with his Staff.

The Assistant-Registrar, William Henry Allchin, Esq., M.B.Lond., F.R.C.P., bearing the Charter and Statutes of the College, bound in crimson velvet adorned with silver. (This copy was presented by Dr. Caius, President of the College in 1555.)

The Four Censors:

Senior Censor—Samuel Osborne Habershon, Esq., M.D. Lond., F.R.C.P.

Second Censor—William Henry Stone, Esq., M.B. Lond., F.R.C.P.

Third Censor—James Edward Pollock, Esq., M.D. Aberd., F.R.C.P.

Fourth Censor—William Howship Dickinson, Esq., M.D., Cant., F.R.C.P.

The Treasurer, Dyce Duckworth, Esq., M.D. Edin., F.R.C.P., bearing the Keys of the Chest.

The Registrar, Sir Henry Alfred Pitman, M.D.Cant., F.R.C.P. bearing the Seal of the Corporation.

The Bedell, Mr. William Garner, carrying the Mace.

The President of the Royal College of Physicians of London, Sir William Jenner, Bart., K.C.B., M.D.Lond, F.R.C.P., D.C.L. Oxon., LL.D. Cant. and Edin., F.R.S.

The Senior Vice-President, Edmund Lloyd Birkett, Esq., M.D.Cant., F.R.C.P.

The Junior Vice-President, John William Ogle, Esq., M.D. Oxon., F.R.C.P.

Their insignia of office having been deposited on a table prepared for them, the President and the two Vice-Presidents will take their appointed places in the arena, and the others will retire to their seats.

At 12.25 the President of the Royal College of Physicians and the President of the Royal College of Surgeons will retire to receive Her Majesty the Queen at the entrance.

On the Queen's arrival the band will play the National Anthem, and the guard of honour formed by the Volunteer Medical Staff Corps and a field officers' guard of the Artists' Volunteer Corps will receive Her Majesty with a Royal salute. The Queen will be met by the Secretary of State for the Home Department, the Chancellor of the Duchy of Lancaster, the President of the Royal College of Physicians, and the President of the Royal College of Surgeons. Two verses of the National Anthem will be sung by the Savoy Choir. Prayer will be offered by his Grace the Archbishop of Canterbury.

Then will follow the presentation of the Address, to which Her Majesty the Queen will graciously reply.

The President of the Royal College of Physicians and the President of the Royal College of Surgeons will each deposit below the stone to be laid a sealed glass vessel containing coins of the present year, some daily papers, and a copy of their respective College lists.

The Queen will then proceed to lay the Stone, the trowel being delivered to Her Majesty by Stephen Salter, Esq., architect of the building.

Presentations will be made to Her Majesty the Queen by Sir William Jenner, Bart., K.C.B. The Archbishop will then pronounce the Benediction and the Queen will leave, the band playing the National Anthem and the guard of honour giving a Royal salute.

DECREASE OF GENERAL PARALYSIS IN EDINBURGH.

THE following passage of general medical interest occurred in Dr. Clouston's annual report of the Royal Edinburgh Asylum at Morningside for 1885, read at the annual meeting of that corporation, held in the Council Chambers, Edinbugh, on Feb. 22nd, 1886, the Lord Provost presiding.

"In addition to this economical cause (increase of rates of board) of decrease of our pauper lunacy (fifty new cases a year), I have reason to think that in the past five years there has been a real diminution of mental disease. In my last year's report I pointed out that the proportion of cases of the disease due to alcoholic excess did not appear to have been greater in the five years of plenty 1873-77 than in the five lean years 1880-84, and this year contributes the usual alcoholic quota of over 15 per cent. But instead of taking a prominent cause of insanity like alcohol, if we take a more definite test—viz., the most marked of all forms of insanity, general paralysis, a form perfectly distinct from every other—we get a result that undoubtedly points to a real diminution of brain disease with mental symptoms in the past five years. General paralysis is more commonly than any other form directly produced by wrong habits and modes of life. Its causes appear most vividly by the fact that it is the form of insanity that comprises one-sixth of all the mental disease among the Durham miners in prosperous times. It is, in fact, that form that is least dependent for its production on hereditary and unpreventable influences, and most dependent on controllable causes operating during the life of the individual. Now, in the first five years of my occupancy of my present office, 1873-1877, mostly years of plenty and inflation of wages, we had 115 cases of general paralysis sent here out of 1580 of total admissions, or 7·3 per cent. of the whole; in the last five years, 1881-1885, years of dull trade and little money to squander, we had only 75 cases out of a total of 1667 admissions, or 4½ per cent. Such a fall in the prevalence of any important and typical disease, comparing one period of five years with another, is a most striking fact from a medical point of view. And whether this has resulted from lessened opportunity of drink and dissipation, or greater exercise of self-control, or a lessened excitement in the modes of life, it is a most suggestive social fact. I think the prevalence of general paralysis may fairly be taken as the index of the prevalence of preventable insanity. While there is a greater proportion of insane persons to the general population of the same years between fifty and sixty (1 to every 160), the largest proportionate number of the newly occurring cases of insanity every year is found between the ages of forty and fifty. During the last thirty years the average age of the new cases (the admissions to asylums) has steadily increased. The conclusion from this

Digitized by Google

would seem to be that the older parts of the general population are getting more subject to mental disease than they were. I think this would be fallacious. I believe the fact to be simply that more people in their restless and troublesome dotage and after paralytic shocks are now sent to asylums, and so come under the category of technical insanity than formerly. There is, however, a variety of mental disease connected with advanced years which it is my impression is becoming more common of late. It is not the typical senile break-down in mind occurring after seventy, but a very sudden break-down soon after sixty, or even before that, in men who have worked hard and continuously, their work perhaps accompanied by excitement, strain, worry, or too high living. It is, in reality, climacteric insanity in the male sex, rather than senile insanity proper."

MEDICAL ORGANISATION IN THE FIELD.

SURGEON-MAJOR EVATT, medical staff, delivered a lecture at the Medical School, Queen's College, Birmingham, on Wednesday, the 10th inst., on the Medical Arrangements of an English Army Corps in the Field. He explained by means of diagrams the organisation of an army corps, and then detailed the medical system. Beginning at the front line in battle, he explained the journey of an ideal soldier of the Warwickshire Regiment, struck down on the field, through various stages, until he finally returned to Birmingham. He illustrated by sketches the battalion aid, the bearer companies of the division, the *personnel*, equipment, and system of the field hospitals, the working of sick convoys, of stationary hospitals on the communication line, of the base hospital with its heavy pressure of work, the journey to England in the hospital ships, and finally the home landing. Turning now to the volunteer service, Dr. Evatt pointed out its complete inefficiency from the medical, commissariat, and transport points of view, and then he dwelt on the methods by which the medical service could be made more efficient. He proposed that every county should have an extension of the existing battalion aid, a definite bearer company, and a field hospital manned by the volunteer medical staff corps. Such companies should be grouped into an administrative battalion for the military district, with an officer of the medical staff of the army as adjutant, and a brigade surgeon of volunteers as commandant. The whole to be under the command of the military principal medical officer of the district, in the same way that the volunteer engineers are under the district commanding engineer. Surgeon-Major Evatt then suggested that with the view of training officers for this volunteer medical corps, the students, while students, should receive the drill and discipline of the medical staff corps, as volunteers, so as to be fit for the position of officers when they have passed their medical and surgical examinations. These may be gone through with honour by a junior, who, for want of special training, might be of comparatively little use in charge of men in the field. It is a singular fact that while Birmingham and the surrounding populous district is a fertile recruiting-ground for the army and navy, only a comparatively very small number of the local medical students enter the public service. This point was specially dwelt upon by Professor Bennett May in seconding a vote of thanks to Dr. Evatt, which was proposed in eloquent and flattering terms by Professor Oliver Pemberton.

THE BOYLSTON PRIZE.—The Boylston Medical Committee, appointed by the President and Fellows of Harvard University, have selected the following as subjects for the essays for this prize in 1887:—The Identification of Human Blood in Suspected Stains, and Original Investigations on the Pathology of so-called Uræmic Symptoms. The author of a dissertation on either of the above subjects considered worthy of a prize will be entitled to a premium of $200.

BOSTON INFIRMARY.—At the annual meeting of the subscribers to and friends of this institution on the 11th inst., it was reported that during the past year there had been a large increase in the number of in-patients, which amounted to 687, being 187 in excess of the previous year. The expenditure amounted to £4199, a sum which exceeded the income by £541.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Hastings Urban District.—This district experienced last year the lowest death-rate for a period of eleven years—namely, 14·2 per 1000 living; the death-rate under one year of age reached only 9·9 per cent. of the registered births; and the zymotic rate of 1·27 per 1000 was also exceptionally low. Small-pox had to be dealt with at the sanatorium, and just as the epidemic appeared to be decreasing it broke out again, chiefly, however, in the rural district. This, as Mr. Knox Shaw says, is not within the jurisdiction of the urban authority, but if, as he seems to imply, the disease was due to spread from the urban hospital, it behoves the town authorities, although they received patients from the rural district, to deal with the matter even more than if the disease had solely extended to their own district. We fear, from the character of the so-called sanatorium that was in use at the time, that the complaint which has been made as to this is very likely to have some foundation, and we should advocate its abandonment. Already a temporary structure has been provided, and it is to be hoped that no further attempt will be made to repeat the experience of the past year as regards the isolation of small-pox in the old sanatorium. From the working of a sunshine recorder, it would appear that 1885 exhibited a marked improvement on the previous year in the number of hours of bright sunshine recorded.

Halifax Combined Districts.—Dr. Britton, in drawing attention to the action taken with a view of preparing this combined district against cholera importation, very properly reminds the authorities that all such preparations fortunately tend, quite irrespective of cholera, to the benefit, both present and future, of the district where they are adopted, and that hence none of the trouble and expense taken and incurred are thrown away. This is essentially true; and some of the sanitary work which has saved most life in this country has resulted from improvements intended primarily to cope with impending importations of disease, which were fortunately warded off. The separate reports addressed to the several constituent authorities contain information as to disease and death, and as to the sanitary circumstances which prevail and need remedy. At Brighouse, for example, the authority are commencing excellent work with a view of improving the existing methods of privy accommodation; they have also very properly relieved the occupiers of the duty of cleansing and emptying receptacles for filth and refuse, but it has been done by contract, and this system is obviously one which can never be expected to work as efficiently as when the authority themselves undertake the task. Another point adverted to, and which is of practical importance, is that of the drainage of cellars. Dr. Britton points out that, apart from very exceptional circumstances, cellars should not be drained, since the traps, even when efficiently constructed, are apt to get dry, and then they favour the admission of foul drain-air direct into the houses. Cellars should be under-drained, so as to keep the subsoil dry; but they need have no means of drainage for their surface, for such water as is used in cleansing them can easily be taken up by cloths or otherwise during the process. The details of the report are of much local interest, and they are sufficiently complete to supply a good deal of useful information. In his general report Dr. Britton adverts to the fact that his third term of office closes with this month. We trust that nothing will occur to break the continuity of the excellent work which he has now for so long a period supervised with judgment and ability.

Withington Urban District.—The death-rate for this district is low. In 1884 it was 13·5 per 1000, and last year it was 13·9 on a population now estimated at 18,000; the zymotic death-rate is also a satisfactory one. In his report Dr. Railton gives an account of the several diseases which have been prevalent, and of the action taken with regard to them, including isolation in the Monsall Infectious Hospital; and he then describes the sanitary circumstances of the district at the end of the year. The information given under the various headings in which the several conditions are

Digitized by Google

dealt with goes to show that good supervision is maintained, and that improvements are steadily in progress. A special report is also appended on the pollution of the streams which flow through the district. Withington itself has dealt with its sewage with a view to prevent pollution of the Chorlton brook, which joins the Mersey, but the latter stream remains largely fouled by other means. So also the Chorlton brook itself is still polluted, and in anticipation of action, which will doubtless be taken by the Manchester Ship Canal Company, investigation has been made of the various sources of pollution which reach the several streams flowing through the Withington district. The pollutions in question all appear to arise in neighbouring sanitary districts, and the Withington authority are advised to commence at once by taking proceedings against offenders under the Rivers Pollution Act.

Bristol Urban and Port Districts.—Mr. Davies, the veteran medical officer of health for Bristol, takes leave of his authority in this his last annual report, and he will carry with him in his retirement the gratitude of all who are capable of appreciating the eminent services he has rendered. The city of Bristol had a death-rate of 19·6 per 1000 during 1885. But though this exhibits a slight increase on the rate for 1884, Mr. Davies believes that his district will stand, as heretofore, at the head of the large towns and cities in point of healthiness. Amongst the local conditions which, according to Mr. Davies, account for this enviable pre-eminence are the following:—1. An excellent system of sewers, designed and carried out in 1851. Mr. Davies regards it as fortunate that Bristol has brick sewers of large capacity—some being 8 ft. in diameter—as opposed to small pipe sewers. This may be fortunate under the circumstances of Bristol; but as a general rule it is not advisable to make sewers larger than is necessary for the purposes of rapidly carrying away the contents they are likely to receive. 2. Bristol has an admirable water-supply from the Mendip hills, and it is a matter of congratulation to hear from Mr. Davies that during his twenty-one years' service as medical officer of health he has never known a case of disease attributed to this water. 3. The great axiom that cleanliness is next to godliness has influenced the sanitary department of Bristol in all its dealings; the result being that dirt in all its forms and shapes has been regarded as an enemy to public health, which must at all hazards be put down. The child-mortality of Bristol is on the increase, and Mr. Davies reminds the Corporation of his prophetic utterance, to the effect that with the extension of factories, and the consequent greater occupation of females as breadwinners, such an increase would take place. The deaths under one year of every 1000 registered births were 133·9 in 1883; they were 145·3 in 1884; and last year they had risen to 155. Mr. Davies again urges the view that any social arrangement, or even philanthropic charity, that removes woman from one of the chief duties of her sex has for a result an increase of infant mortality. Of 61 cases of small-pox that came under notice 44 were isolated in hospital, 18 being removed to the Corporation small-pox hospital. On the other hand, although there were 21 deaths from scarlet fever, 25 from diphtheria, and 16 from "fever," it was only found necessary to isolate 8 cases in the fever hospital belonging to the authority. Some of the fatal attacks set down as due to enteric fever were not properly so designated, according to Mr. Davies, who states that there has been much loose teaching in this respect.

Bristol Port District.—The report on this district is accompanied by a very useful map, showing the boundaries of the port and the relation which it bears to neighbouring places. The inspection of ships was carried out most methodically during 1885 with the aid of Dr. Heaven, assistant port medical officer, and, where needed, the cleansing and disinfection of vessels were thoroughly enforced. The new sanitary hospital at Avonmouth was completed during the year, and it was found invaluable in dealing with small-pox imported from Montreal. It was also kept in readiness for the purposes of any cholera that might have been imported, but fortunately the port of Bristol escaped.

ON the 15th inst., the House of Lords gave judgment in the case of Abrath *v.* the North-Eastern Railway Company, which was an action for malicious prosecution. The courts below decided against the plaintiff, and this decision was upheld by the House of Lords.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6195 births and 4873 deaths were registered during the week ending March 13th. The annual death-rate in these towns, which had increased in the six preceding weeks, from 22·1 to 26·6, further rose last week to 28·0, and exceeded the rate recorded in any week since February, 1882. During the first ten weeks of the current quarter the death-rate in these towns averaged 28·9 per 1000, which was 0·5 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 19·3 in Brighton, 19·6 in Sheffield, and 19·9 in Derby. The rates in the other towns ranged upwards to 33·8 in Liverpool, 34·3 in Salford, 35·4 in Plymouth, and 35·7 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 384 and 404 in the preceding two weeks, further rose last week to 430; they included 191 from whooping-cough, 122 from measles, 36 from diarrhœa, 31 from "fever" (principally enteric), 30 from scarlet fever, 18 from diphtheria, and 2 from small-pox. No death from any of these zymotic diseases was recorded last week in Huddersfield; whereas they caused the highest death-rates in Portsmouth, Nottingham, Bolton, and Blackburn. Whooping-cough caused the greatest mortality in Sunderland, Portsmouth, and Bolton; measles in Preston, Oldham, Nottingham, Plymouth, and Blackburn; scarlet fever in Salford; and "fever" in Wolverhampton. The 18 deaths from diphtheria in the twenty-eight towns included 14 in London. Small-pox caused 2 deaths in Liverpool, and not one either in London or in any of the twenty-six other large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 15 and 7 on the preceding two Saturdays, were again 7 at the end of last week; one case was admitted to these hospitals during the week, against 7 and 0 in the preceding two weeks. The Highgate Small-pox Hospital contained 3 patients on Saturday last, one case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had increased in the preceding seven weeks from 477 to 745, further rose last week to 855, and exceeded the corrected weekly average by 385. The causes of 143, or 3·0 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Plymouth, Birkenhead, and Huddersfield. The largest proportions of uncertified deaths were registered in Halifax, Oldham, Hull, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 22·3, 23·5, and 24·9 per 1000 in the preceding three weeks, further rose to 27·5 in the week ending March 13th, but was 0·5 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 14·8 in Perth and 21·4 in Edinburgh, to 30·4 in Paisley and 33·6 in Glasgow. The 678 deaths in the eight towns showed a further increase of 64 upon the numbers in recent weeks, and included 20 which were referred to whooping-cough, 11 to diarrhœa, 6 to measles, 5 to scarlet fever, 5 to diphtheria, 4 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 51 deaths resulted from these zymotic diseases, against 51 and 43 in the preceding two weeks. These 51 deaths were equal to an annual rate of 2·1 per 1000, which was 0·5 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 19 in each of the previous two weeks, were 20 last week, all of which occurred in Glasgow. The 11 deaths attributed to diarrhœa showed an increase of 4 upon the low number in the previous week, but were 6 below those returned in the corresponding week of last year. All the 6 fatal cases of measles were returned in Edinburgh; and 4 of the 5 deaths both from scarlet fever and from diphtheria occurred in Glasgow. The deaths referred to "fever," which have been 6 and 7 in the preceding two weeks, declined last week to 4, including 3 in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had increased in the preceding five

Digitized by Google

weeks from 135 to 170, further rose last week to 191, and exceeded the number in the corresponding week of last year by 69. The causes of 91, or 18 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had declined in the preceding four weeks from 38·6 to 30·1 per 1000, rose again to 38·3 in the week ending March 13th. During the first ten weeks of the current quarter the death-rate in the city averaged, no less than 32·7 per 1000; the mean rate during the same period did not exceed 24·4 in London and 19·2 in Edinburgh. The 259 deaths in Dublin last week showed an increase of 55 upon the number returned in the previous week and included 19 which were referred to the principal zymotic diseases, against numbers declining from 26 to 15 in the previous four weeks; 11 resulted from whooping-cough, 6 from "fever" (typhus, enteric, or simple), 1 from scarlet fever, 1 from diarrhœa, and not one either from small-pox, measles, or diphtheria. These 19 deaths were equal to an annual rate of 2·8 per 1000; the rates from the same diseases being 2·6 in London and 1·6 in Edinburgh. The fatal cases of whooping-cough, which had been 18 and 10 in the previous two weeks, were 11 last week. The 6 deaths from "fever" showed a further increase of 2 upon the low numbers in recent weeks. Seven inquest cases and 6 deaths from violence were registered, and 68, or considerably more than a quarter of the deaths were recorded in public institutions. The deaths of infants showed an increase upon recent weekly numbers, while those of elderly persons had somewhat declined. The causes of 38, or nearly 15 per cent., of the deaths registered during the week were not certified.

"Audi alteram partem."

AMBIGUOUS ILLNESS AND DEATH.

To the Editor of THE LANCET.

SIR,—The ambiguous illness and death of a member of the profession so well known and so much esteemed as Mr. Cooper Forster, who appeared but a short time before to be in the fulness of health and exceptional constitutional vigour, cannot fail to have attracted the attention of the profession through the clear and candid accounts published in your last number by Dr. Wilks and Mr. Jonathan Hutchinson, together with the note of the post-mortem made by Dr. Anderson and Mr. Hutchinson, jun. This case will be sure to call to the memory of most men of clinical experience, both in hospital and private practice, instances of illness in which the most thorough investigation fails to justify a name being given to an unusual and ambiguous set of grave symptoms. Disease is not an entity, but the expression of variable and complex deviations from health usually presented with regularity and order sufficient to admit of being classed or grouped and named as a disease; but sometimes these complex and variable deviations from natural functions and structure are presented in such irregular and rare forms as to give no one individual, nor indeed the whole profession, such knowledge and experience of them as to justify their classification so as to enable them to be named. Of this kind was the illness of Mr. Cooper Forster, as well as that of "unusual rash" on which you annotated in your issue of March 13th (see THE LANCET for 1876, page 113, for cases of Lichen Planus, by Tilbury Fox), which does not appear so fatal as Mr. Hutchinson represents. These two cases of illness attended by indefinable rash and other unusual symptoms, and neither admitting of a diagnosis in accordance with the accepted classification of disease, even when seen in one case by Dr. Julius Pollock, Dr. Samuel Gee, and Mr. Pollock, and in the other by Dr. Habershon, Dr. Wilks, Sir James Paget, and Mr. Jonathan Hutchinson, all men of the largest professional knowledge and experience, point to fields for research as yet unexplored. When cases such as these fall to the lot of the isolated practitioner he must indeed feel a weight of responsibility; and if this be accompanied by some mistrust of his powers, he may derive consolation from the fact that there are illnesses going on to a fatal issue which the greatest combination of learning and skill in consultation is not able either to name or diagnose. Viewed in retrospect through the published accounts, the points to note in Mr. Cooper Forster's illness are:—1. That there was a rash resembling lichen planus before he left London for the Riviera on Jan. 21st, but there was no other deviation from his accustomed good health. 2. It was not till he had left London and sojourned in the Riviera for a week or so that he first felt unwell; the first appearance of the rash and first indisposition were thus not coincident, and apparently not intimately connected. 3. Loss of appetite and strength after the first week in the Riviera was the first constitutional symptom, but there was no quickening of pulse; yet the condition on his reaching London, after touring about in the Riviera for from three weeks to a month, was that of a distinct fever, suspected to be typhoid, with an afternoon temperature of from 102° to 103°, but still with no quickening of pulse beyond 80 beats, except just preceding death. 4. The fever was proved at the post-mortem not to be typhoid; yet the blood and bile-stained organs left no doubt that there had been a blood disease of the nature of fever. 5. The lung congestion and pleuritic effusion were secondary and insufficient to have caused death, and Sir James Paget was clear upon the point that the case was not pyæmic. 6. The rise and fall of morning and afternoon temperature was periodic and regular in height at these respective times, and not accompanied by a corresponding rise in the pulse-rate. 7. The illness commenced while touring in a locality known to be visited from time to time by malaria, and the spleen was enlarged as if from malarial infection. Malarial fever resembling typhoid has been the subject of much comment in your columns of late.

The question naturally arises, Was not Mr. Cooper Forster's illness an instance of malarial fever resembling typhoid brought to a climax by chill, excessive fatigue, and abstinence from nourishment? The initial rigor, so conspicuous by its absence in his illness, is often absent in malarial fevers, while active development is well known to be coincident with chill, fatigue, or abstinence from nourishment in persons previously exposed to the poison. Two years ago I had a patient come straight from Monte Carlo with symptoms very like those in Mr. Cooper Forster. Dr. Bennett in his work on the Riviera asserts that for two summers many cases of malaria occurred even at Mentone, and that malarial fevers may be generated there by mere chills.

I am, Sir, yours obediently,

March 15th, 1886. A GENERAL PRACTITIONER.

To the Editor of THE LANCET.

SIR,—The account published in your last issue of the fatal illness of Mr. Cooper Forster forcibly reminds me of some cases met with last year at Suakim, and recently brought before the Medico-Chirurgical Society. The resemblance to one of these cases in particular is, excepting as to diarrhœa, remarkably close. During life less cerebral oppression and increased tendency to vomiting alone distinguished these cases from typhoid, for at Suakim the prevalent diarrhœa was present in all cases, and prevented a clear diagnosis. Diarrhœa is, however, not a constant symptom in such cases (see THE LANCET, Sept. 19th, 1885, p. 518). A similar form of fever is found, I believe, at Malta, Naples, Sicily, and Rome; but this, as far as I know, is the first recorded instance of its being met with so far north as the Riviera.

I am, Sir, yours obediently,

J. EDWARD SQUIRE, M.D.

Orchard-street, W., March 16th, 1886.

To the Editor of THE LANCET.

SIR,—There is evidently much doubt as to the nature of the disease of which Mr. Cooper Forster died, and the account of the necropsy, as reported in last week's LANCET, does not clear it away. In looking over the notes of the necropsy, I find no mention is made as to the condition of the supra-renal bodies. Is it possible that the patient died of Addison's disease, and that the eruption stated to be a prominent symptom was partial bronzing of the skin? The statement that Mr. Forster was in full health when he started on his continental tour is of course against this view of the case; but the nausea, the loathing of food, and the great and sudden prostration are in favour of it. Some

Digitized by Google

five or six years ago we admitted a man into the West Norfolk and Lynn Hospital whose history was simply that of a few weeks' gradually increasing debility and more or less bronzing of the skin. The patient was brought into the hospital in a state of utter prostration, death taking place in a week or ten days, and whilst under observation there was no sickness and no pain. Addison's disease was diagnosed on examination after death, and the supra-renal bodies were typically diseased.

I remain, Sir, yours obediently,

WILLIAM DALE, M.D. Lond.

King's Lynn, Norfolk, March 16th, 1886.

CYCLICAL ALBUMINURIA.

To the Editor of THE LANCET.

SIR,—Dr. Pavy appears to wish to give this name to the condition called by Dr. Moxon the albuminuria of adolescents, on the ground that in this form of albuminuria the maximum albumen of the twenty-four hours is found during the after-breakfast period.

In the *British Medical Journal* for June 5th, 1880, p. 841, there is a paper of mine which was read at the meeting the previous year at Bath, in which this periodical excretion of albuminuria is fully described and compared with the diurnal variations in the urea, pulse, and respiration to which Dr. Edward Smith first drew attention. But my cases were cases of Bright's disease, and if Dr. Pavy means to assert that this diurnal variation is absent in Bright's disease, and present in these cases only, he is, according to my observation, wrong. My paper has been quite accessible; but as no one has remembered it, I may be pardoned for quoting one of my tables.

Diet: Breakfast, 5 A.M., two slices of bread-and-butter, with tea; lunch, 10 A.M., two slices of bread-and-butter, one pint of milk; dinner, 1 P.M., four ounces of cooked meat, eight ounces of potatoes, bread and water; tea, 6 P.M., same as breakfast; supper, 7 P.M., half a pint of milk. Exercise: walking twice daily for half an hour, at 12.30 and 2.30 P.M.

Date.	Period.	Total urine.	Albumen in 40 cubic centimetres.	Total albumen.
		Cub. cent.	Gramme.	Gramme.
March 10th	7 P.M. to 5 A.M.	1630	·008	·1296
	5 A.M. to 1 P.M.	150	·016	·06
	1 P.M. to 5 P.M.	180	·01	·045
	5 P.M. to 7 P.M.	120	·008	·021
March 12th	7 P.M. to 5 A.M.	870	·0069	·1479
	5 A.M. to 1 P.M.	180	·017	·0756
	1 P.M. to 5 P.M.	180	·0141	·0630
	5 P.M. to 7 P.M.	150	·009	·0330
March 13th	7 P.M. to 5 A.M.	1410	·0155	·5358
	5 A.M. to 1 P.M.	180	·020	·090
	1 P.M. to 5 P.M.	180	·0166	·0738
	5 P.M. to 7 P.M.	120	·015	·0444

This was a case of Bright's disease, and he was put on this diet for the purposes of this experiment. It is interesting to note that the nitrogenous diet, while not having the immediate effect of increasing the albumen passed during the corresponding periods, yet showed a very decided power of increasing the total albumen, which rose by the third day to three times what it was on the first.

I am, Sir, yours obediently,

Birmingham, March 9th, 1886. ROBERT SAUNDBY, M.D.

A CASE OF APOPLEXY, WITH COMPLETE HEMIPLEGIA, AT THE AGE OF TWENTY-FIVE.

To the Editor of THE LANCET.

SIR,—The following case may be interesting to your readers.

Miss G. W——, aged twenty-five, a schoolmistress, consulted me early last October for shortness of breath and difficulty of getting up-hill. She was anæmic, of slight build, and with auburn hair; the catamenia were regular, though of small quantity. She felt well, and her appetite was good. On examination the heart was working away with a great thrill all over the left breast, and continued up the subclavian and carotids, but more so on the right side—in fact the anæmic bruit. There was no valvular disease. On iron and digitalis she improved, which was afterwards changed to compound iron mixture. I saw her now and then, she continuing well and able to go on with her duties, when on Sunday, Dec. 13th, at about 7.30 P.M., I was called out of church to go to her (she living about five miles away), the messenger saying she was speechless and had great pain in her right arm. On arrival I found her unconscious, unable to speak, mouth slightly drawn to the right side, both pupils dilated and unanswerable to light, face swollen, unable to protrude the tongue, right arm and leg paralysed but warm, no involuntary evacuation of bladder or bowel, with her hand pressed against the left side of the head. Her friends told me that she had been "out of sorts" for the last two days, and that while sitting before the fire during the evening she got up to put on some coals and fell back into her chair, in which position I found her. I ordered mustard to be applied to the neck &c., also calomel and a mixture.—Dec. 14th: Unconscious, the same as last night; passed no urine; bowels not moved. I passed a catheter, ordered a turpentine injection, and a blister to the left side of the head.—15th: Bowels open; passed a little urine in bed.—16th: Bowels open with injection; passed urine, and she knew when she wished to do so. More conscious; knows me; pupils answer to light, though not quite enough: swelling of face reduced; tongue can be protruded, but goes to right side; no pain.—19th: Has been going on favourably: quite conscious for the last few days; able to eat with a relish; bowels and bladder act regularly and naturally; paralysed parts keep warm, but are useless. I ordered her absorbents and nerve tonics, also galvanism.—22nd: Got her up in the arm-chair; cannot speak, though she can make her friends understand what she wants.—28th: Has said "No," "Yes"; objects a good deal to the battery; is progressing in strength.—31st: Is able, while standing, to lift her paralysed leg about two inches and a half from the ground; the arm remaining the same; can read a verse in the Bible.—Feb. 6th: The patient has been steadily mending; her speech is slow, but stronger; able now to walk downstairs step by step; can lift her arm towards her head: all functions regular; is looking very well, but inclined to laugh at a trifle. The patient now passed out of my hands into the Cottage Hospital, where I trust she will make as good a progress as at her humble home.

Query, is it sanguineous or serous effusion or hysteria? I am inclined to serous effusion. I heard since that she was troubled about her school not passing, whereby she lost her certificate.

I am, Sir, yours truly,

WILLIAM FRASER, M.B. Univ. Dub.

Ashburton, Devon, Feb. 9th, 1886.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE NEWCASTLE CHILDREN'S HOSPITAL.

THE munificent offer of Mr. Fleming, of this city, to build and furnish a new children's hospital for Newcastle and its vicinity, at a probable cost of £15,000, has caused the charity to become a subject of conversation of late in medical and general circles. The gift of Mr. Fleming has also created some difficulty in the minds of the friends of the institution. By the terms of the gift the hospital is to be removed to the outskirts of the city, at least two miles from the parts of the town most in need of out-patient relief; and as this latter has always contributed the most important part of the children's hospital work, it must needs follow that unless some adequate provision is made for carrying on the work of the out-patient department in the centre of the town, the removal of the hospital will do a great deal of harm, and even if this provision is made it is feared the division of labour in the medical departments will not be found to work well. Many old friends of the institution think that a good central hospital with a limited number of beds, and a small convalescent hospital (a want generally admitted) in the suburbs, would offer most benefit for the sick poor. Then, again, the subject of the endowment or support of a large hospital as proposed will require most anxious consideration when most of our medical charities show a diminishing income. Mr. Fleming's offer is a handsome one no doubt, but the considerations just alluded to ought to be well weighed by

Digitized by Google

the governors. I should have mentioned, when speaking of the medical founders of the hospital in my last letter, that Mrs. Sedman of Leeds, Sir William and Lady Armstrong, Miss Jane Mather, and the late Mr. Joseph Mather of this city greatly aided Dr. William Murray and Mr. J. B. Fife in establishing the hospital, and that Dr. Murray is consulting physician and Mr. Fife consulting surgeon to the institution.

NEWCASTLE DISPENSARY.

The annual meeting of this dispensary, a very old charity, was lately held in this city, and the report (the 108th) was on the whole very satisfactory. The medical officer resident in the institution stated that the number of patients admitted to the benefits of the charity showed an increase of 967 as compared with the previous twelve months. There was also an increase of 1287 in the number of casual patients. Dr. Beatley states that during the early part of last year a severe epidemic of measles caused a great strain to be thrown on the medical staff and the resources of the institution. The number of patients admitted by letter during the year had been 7027, in addition to 550 under treatment at the beginning of the year, making a total of 7577. Of these 6318 had been cured or relieved, 94 sent to the Infirmary Fever House &c., 654 died, and 511 remain under treatment. The casual patients admitted with letters during the year numbered 13,426, making a total of 21,003 cases treated. It is pointed out in his report that the 7027 letter patients constituted the largest number of this class treated in any one year, and that it was among the home patients that the largest increase was apparent. The percentage of deaths was higher than in 1884; this is accounted for by the severe epidemic of measles and the distress amongst the poor of the city. It is pointed out that there has been no death certified amongst the casuals; children are occasionally brought to the dispensary at the last moment, but the medical officer has adopted the practice of referring such cases to the coroner. Dr. Beatley bears testimony to the good work done in conjunction with the medical officers to the sick poor by the Cathedral Nurse and Loan Society, by skilful nursing, and the supply of nourishment and appliances in many difficult cases. In reference to a clause in the report, showing the mortality from measles treated at the dispensary to have been 108 fatal cases in a total of 1062 affected, or 10 per cent., a governor said that the question arose whether the time had not arrived when such cases should at once be reported to the medical officer of health, with a view to steps being taken to stop the spread of the disease.

BEQUESTS TO CARLISLE CHARITIES.

The late Miss Frances Barnes of Carlisle has left several legacies to the charities of that city, including the following:—Border Counties Home for Incurables, £500; Cumberland Infirmary, £500; Asylum for Idiots, £500; Silloth Convalescent Institution, £500; Carlisle Dispensary, £300.

Newcastle-on-Tyne, March 16th.

EDINBURGH.

(From our own Correspondent.)

PROFESSOR SIR WILLIAM TURNER.

THE honour of knighthood has been proffered to and accepted by Professor Turner, who has now for nearly twenty years occupied the Chair of Anatomy in the University of Edinburgh. The honour which has thus been conferred was one thoroughly merited by the distinguished career achieved by our professor of anatomy, who, by the thoroughness of his teaching, as well as by his great organising and administrative powers, has done so much to extend the fame and to enhance the welfare of the University of Edinburgh. The intimation of the honour which has been done him has been greeted in Edinburgh with universal approbation, a sentiment which will be united in by numbers of his old students now scattered over the country, who have become acquainted with his sterling qualities whilst studying in his department during their medical curriculum. On Wednesday week at 1 o'clock, the usual hour for the lecture on anatomy, Sir William Turner was welcomed by an enthusiastic crowd of students who had assembled to congratulate him upon his newly conferred honour. A congratulory address from the members of the anatomy class was presented to him, in which the students expressed their esteem for him as a teacher and their sense of the distinguished career in the pursuit of anatomical science which has so well merited the honour now conferred. In reply to the address, Sir William referred to the numerous expressions of goodwill of which he has been the recipient during the thirty-two years of his connexion with the University of Edinburgh, but stated that he had never dreamed of being a party to such an overpowering demonstration as they had given him that day. As a member of the teaching staff of the University he had accepted the distinction of a knighthood as a recognition of the work being done by the University, and as no mere personal compliment. He concluded by announcing a holiday for that day. The proceedings, which were throughout very enthusiastic, terminated amidst prolonged and reiterated cheering.

THE LATE DR. JOHN BISHOP.

The death of Dr. Bishop, which took place a few days ago at Cannes, has been heard of with deep regret by a wide circle of friends in Edinburgh. Till about two years ago Dr. Bishop was resident in Edinburgh, where he engaged in practice as a surgeon, and where he held the post of assistant-surgeon to the Royal Infirmary. About that time his health became impaired in consequence of an erysipelatous attack contracted whilst carrying on his hospital duties. This illness he never fully recovered from, for it was followed closely by the onset of an attack of profound anæmia, which, after running a prolonged course, has terminated fatally. Dr. Bishop's career as a student was a distinguished one; he was known to be intimately acquainted with philosophical and logical literature, and he brought all the trained acumen of a well-balanced mind to bear upon his medical studies. He was an authority upon antiseptic surgery, and the subjects connected with it, and he obtained a gold medal for his M.D. thesis upon this subject. By his personal characteristics he attracted a large circle of acquaintance, amongst whom he was valued as a true-hearted and generous friend. About five years ago he married Miss Bird, the authoress of several widely known books of travel, by whom he is survived.

IRELAND.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

As previously announced in these columns, there were three candidates in the field for the Vice-Presidency for the ensuing year, the election for which takes place early in June. The three candidates, Messrs. Frazer, Fitzgibbon, and Corley, appeared resolved to contest the matter, but I am glad to state that Mr. Fitzgibbon has, on reconsidering the matter, determined to resign in favour of Mr. Corley, believing that gentleman to have a prior claim on the electors. Mr. Fitzgibbon, however, I am informed, will be a candidate for the Vice-Presidency in 1887. Sir James Paget, Bart, one of the new Honorary Fellows, has intimated his intention to be present at the banquet to be given at the College, on the 28th April, by Sir Charles Cameron, and during his stay in Dublin will be the guest of the President.

ROYAL UNIVERSITY OF IRELAND.

The fourth annual report is of a favourable character, and the progress shown during the past three years gives good ground for the belief that the success of the University is assured. At the various academic examinations last year 2534 students presented themselves, being an increase of 433 as compared with the previous year. Lord Emly, whose work the report is, states, in reference to the women students, that they have on the whole been so successful that it is plain greater facilities and an improved character of education would bring about most satisfactory results.

DEATH OF MR. THOMAS DARBY, F.R.C.S.I.

This well-known gentleman died at his residence in Bray on the 10th inst. from an attack of bronchitis, at the advanced age of seventy-eight years, and his somewhat sudden decease will be regretted by a large number of friends. Some years since he was attached as visiting surgeon to Rathdown Workhouse, which post he resigned in order to devote himself entirely to private practice, of which he possessed the lion's share in the fashionable seaside resort in which he resided. At one time he was a candidate for a seat on the

Digitized by Google

council of the College of Surgeons, and lost it by the casting vote of the chairman, which result prevented him ever coming forward again for this office. He was an ex-president of the Irish Medical Association and of the Dublin Obstetrical Society, and filled other positions with credit and efficiency.

ST. JOHN AMBULANCE ASSOCIATION.

The annual meeting of the Dublin Centre of this Association was held on Saturday last in the Senate Hall of the Royal University of Ireland, when the Countess of Aberdeen distributed the awards of the Society. The St. John Medal was bestowed on Dr. E. Charles Thompson for having risked his life in order to save a child suffering from diphtheria. Dr. Thompson is the first on whom this distinction has been conferred in Ireland, and he is also the recipient of the Albert Medal for the same act of heroism.

CITY OF DUBLIN HOSPITAL.

By the bazaar recently held, this institution, which is one of the best-managed hospitals in Dublin, has obtained a sum of £2000 towards the funds of the charity.

Robert Anderson, A.M., M.D., Professor of Natural History, Queen's College, Galway, has been placed on the commission of the peace for the county of Down.

Dublin, March 16th.

PARIS.

(From our own Correspondent.)

THE PARIS FACULTY OF MEDICINE.

THE summer session of the Paris Faculty of Medicine began to-day, the 16th inst., and will be continued in the following order:—Medical Natural History, Professor Baillon; Physiology, Professor Béclard; Surgical Pathology, Professor Guyom; Medical Jurisprudence, Professor Brouardel; Pharmacology, Professor Regnauld; Pathology and General Therapeutics, Professor Bouchard; Medical Pathology, Professor Damaschino; Experimental and Comparative Pathology, Professor Vulpian; Obstetrics, Professor Tarnier; Hygiene, Professor Proust; Materia Medica and Therapeutics, Professor Hayem. Clinics: Medicine—Professor G. Sée, at the Hôtel Dieu; Professor Hardy, La Charité; Professor Potain, Necker Hospital; Professor Jaccoud, La Pitié. Surgery—Professor Richet, Hôtel Dieu; Professor Verneuil, La Pitié; Professor Trélat, La Charité; Professor Le Fort, Necker Hospital. Mental Pathology and Diseases of the Encephalon—Professor Ball, at the St. Anne Asylum. Diseases of Children—Professor Grancher. Syphilitic and Cutaneous Affections—Professor Fournier, at the St. Louis Hospital. Diseases of the Nervous System—Professor Charcot, at the Salpétrière. Ophthalmology—Professor Panas, at the Hôtel Dieu. Clinical Obstetrics—Professor Pajot.

PROPHYLACTIC MEASURES AGAINST COLD.

At a recent meeting of the Société de Biologie, Professor Brown-Séquard read a paper on the Prophylactic Means to be adopted against Accidents resulting from Cold, which he founded on the following theory:—"The neck is one of the regions of the body the most sensitive to cold; there is no doubt that a great number of accidents, such as coryza, laryngitis, bronchitis, cystitis, enteritis, &c., which are reflex phenomena, result from the impression of cold on the nerves of the skin of the neck." To avoid these accidents, M. Brown-Séquard recommends the blowing on the neck with the bellows of warm air, which should be gradually cooled, by which means the neck is rendered less sensitive to the action of cold. The Professor found that ten sittings were sufficient to produce effect.

A VISIT TO M. PASTEUR'S LABORATORY.

I paid a visit this morning to M. Pasteur's laboratory in the Rue d'Ulm, where he performs his anti-rabic inoculations. The sight to be there witnessed is most interesting and curious, for one meets persons of both sexes, of all ages and conditions of life, the poorer classes being in greater number, even people from different parts of the world—Italians, English, Americans, Russians, Poles, &c.,—who were there assembled to submit themselves to M. Pasteur's treatment. The inoculations are performed by Dr. Grancher with a hypodermic syringe in presence of M. Pasteur, and he does from sixty to eighty every morning. The instrument, which is two-thirds full of the inoculating liquid for adults and one-third for youths and children, is thrust into one or other flank, and this operation is repeated every day for ten consecutive mornings. The composition, or rather the constitution, of the liquid employed is known only to M. Pasteur, who manufactures it in his own laboratory. Dr. Grancher told me that as yet no accidents had occurred in the way of abscesses &c., and that the patients go through the process without any constitutional disturbance. It struck me, however, that many of the applicants had been driven there, more from fright than necessity, as in many cases they did not wait to ascertain whether the dogs that bit them were really rabid. In some cases they were not even bitten. For instance, I saw a young English lady who submitted to the operation simply because she had been licked in the mouth by her dog, which had no signs of madness. I met there also Dr. Hime of Bradford, who came over with his party of seven persons, consisting of four little boys, a little girl, a youth, and a man, who Dr. Hime told me were bitten on Jan. 24th by a dog which was ascertained to have been indubitably rabid, as another person who was bitten at the same time by the same dog died soon after from hydrophobia. M. Pasteur had just received a telegram from Berlin to say that nineteen persons bitten by a rabid wolf were forwarded to Paris to undergo his treatment. Subscriptions for a suitable building are pouring in from all quarters, and the Paris Municipal Conseil has under its consideration a proposition for the immediate construction of the Pasteur Institute.

APPOINTMENTS AT THE VETERINARY SCHOOLS.

M. Chauveau, Director of the Veterinary School of Lyons has been appointed Inspector-General of the Veterinary Schools of France, in lieu of M. Henri Bouley, deceased; Professor Arloing is appointed Director of the Veterinary School of Lyons in succession to M. Chauveau.

Paris, March 16th.

MEDICAL NOTES IN PARLIAMENT.

Inoculation for Hydrophobia.

IN the House of Commons, on the 11th inst., in reply to Sir H. Roscoe, Mr. Chamberlain stated that his attention had been called to the reported discovery by M. Pasteur of a cure for hydrophobia. The recognised eminence of M. Pasteur as a scientific investigator, and the great interest and importance which attach to the subject of his recent inquiries, seemed to justify a careful and impartial examination of the results obtained. At present the information on the matter in the possession of the Local Government Board was too vague and incomplete to afford materials for a full appreciation of M. Pasteur's process. He would consider how such an investigation as might enable a just estimate to be formed as to the reliability of M. Pasteur's method and its applicability to this country could be most satisfactorily conducted, and would confer with the Chancellor of the Exchequer with reference to the question of the expense.

Fever at Port Royal.

In reply to Sir J. Goldsmid, Mr. Hibbert stated that he regretted to have to say that since October, 1885, nineteen cases of yellow fever had been admitted into Jamaica Hospital from the *Urgent*, of which number four had terminated fatally. Besides these, an officer who was on board waiting to join the *Wye* was attacked and died. There had been one other case—from the *Tyne*. There was no "sanatorium or hill station" attached to Jamaica Hospital; nor was it thought by the medical advisers of the Government that any such establishment was necessary for such cases of infectious disease, as Port Royal was so swept by the sea breezes that it was considered more healthy than a hill station.

The Hampstead and Homerton Hospitals.

On the 12th inst., in answer to Mr. Gibb, Mr. Chamberlain said that the Hampstead Hospital had not been used for any small-pox patients since July of last year, and if in the event of any epidemic it should be necessary again to use it for small-pox patients it would only be for a very limited number, and in the cases only of patients who, from the acute nature of the disease, could not be removed to any hospital at a distance. The report of Mr. Shirley Murphy had not yet been officially considered by the managers, and consequently no steps had been taken to test the conclusions

Digitized by Google

at which he had arrived. With regard to the Homerton Hospital, the managers had made such arrangements as would, it was believed, prevent the occurrence in the future of such abuses as formed the subject of the recent inquiry, and it did not appear to the Local Goverment Board that there would be any sufficient advantage in a further inquiry by a Royal Commission or a Select Committee.

The Indian Medical Service.

In reply to Sir G. Hunter, Sir W. Kay-Shuttleworth stated that the option of attending the Aldershot course of instruction, which in August, 1882, had been given to Indian medical officers passing through Netley, was inadvertently withdrawn in April, 1884, on the introduction at Netley of a course of bearer company drill. This, however, would now be corrected; and as the Aldershot course must be optional for Indian officers, a reference would be made to the Government of India as to the instruction in that country of those officers who have not passed the Aldershot course.

Contagious Diseases Acts.

On the 16th inst. Mr. Stansfeld moved that the Contagious Diseases Acts, 1866-69, ought to be repealed. The whole subject had been worn threadbare long ago, and no new arguments were adduced either for or against this class of legislation. Mr. Puleston, as representing a garrison town in which the compulsory treatment had been enforced, spoke of the value of the Acts as a repressive and reclamatory agency, and he read a letter from the Town Clerk of Devonport urging that the supporters of the Acts had wavered not a jot in their opinion as to the usefulness in the interests of health and morality of the measure Mr. Stansfeld sought to annul. Sir John Kennaway tried to effect a compromise; but it was admitted on both sides of the House that the feeling of the country was adverse to the Acts, and when the matter came to a division the amendment was negatived by a considerable majority—245 to 131. The motion was then agreed to without a division.

On the 17th inst. Mr. Stansfeld moved for leave to bring in a Bill to repeal the Acts, but Mr. Bentinck objected, and as it was past the hour at which opposed business could be taken the motion dropped.

The Medical Act of 1858.

On the 16th inst., in answer to Dr. Foster, Sir L. Playfair stated that a Bill was being drafted, and would, he hoped, be shortly introduced, to amend the Medical Act of 1858. It will contain provisions to give direct representation to the medical profession on the General Medical Council.

Rags from Spain.

In answer to Mr. Hunter, Mr. Trevelyan said that he had recently approved of an order issued by the Board of Supervision prohibiting the importation of rags from Spain for some months, and had received various recommendations as to the necessity of further legislation, which would have his careful consideration.

THE SERVICES

INDIA OFFICE.—The Queen has approved of the restoration of the undermentioned officer from the half-pay list to the effective list:—Surgeon George Augustus Cones, of the Bengal Army.

The Queen has approved of the following promotion made by the Governments in India:—Surgeon-Major Benjamin Thomas Saffrein, of the Madras Medical Establishment, to be Brigade Surgeon.

ADMIRALTY.—The following appointments have been made:—Surgeon William E. Breton, M.D., to the *Revenge;* Surgeon Hugh W. Macnamara, to the *Asia;* Surgeon Robert M'Ivor, to Plymouth Hospital; Surgeon John A. M'Adam, to the *Indus;* Surgeon A. H. Miller, to Royal Marine Depôt, Walmer; Surgeon James H. Beattie, to the *Vernon:* Surgeon Richard A. Fitch, to the *Cambridge;* and Surgeon W. Spry, to the *Boscawen.*

ARTILLERY VOLUNTEERS.—1st Cheshire and Carnarvonshire: Arthur Montfort Archer, Gent., M.B., to be Acting-Surgeon.

A SUM of 120,000 marks (£6000) has been left to the University of Rostock, for the erection of an ophthalmic hospital.

Obituary.

JOHN STORRAR, M.D. LOND.

DR. STORRAR was so well known to everyone connected with the University of London as its oldest surviving medical graduate, and for twenty-one years its chairman of Convocation, that his death on the 10th inst. at Blackheath will be felt by most of the graduates as a personal loss. He was born in 1811, and was educated at University College. He took his M.D. degree in 1839, with the late Dr. John Taylor, and they were the first medical graduates of the University. Without a qualification from either of the Royal Colleges he practised for several years in Brook-street, and was largely instrumental in securing the passing of the Medical Graduates Act of 1858, by which the members of the University of London were given the same privileges to practise medicine as were enjoyed by the graduates of Oxford and Cambridge, without becoming Members of the Royal College of Physicians. Dr. Storrar's position in this matter was really made a test case. He was for many years secretary to Dr. Somerville, a former inspector of anatomy. The General Medical Council was first constituted in 1858, and on its formation Dr. Storrar was appointed on that body as the representative of the University of London, and had continued as such up to the present time. He was an ardent enthusiast in improving medical education, on the general and scientific lines adopted by his University, and could always be relied on to oppose firmly but courteously any proposition tending to lower medical standards, or to depreciate university influences in favour of the corporations. If he erred in these matters, it was from a thorough belief that nearly all recent advantages in medical education were due to the initiative and example of the University of London. He was also one of the early reformers of that University, who, after a ten years' struggle with the Senate, obtained a new charter from the Crown by which the members of Convocation were allowed to return Fellows to the Senate, and thus have a voice in the management of its affairs. Dr. Storrar was one of the first members of the Senate elected by the votes of the graduates in Convocation, and he always referred to this as one of the greatest honours in his life. His attendance at the meetings of the Senate was a model of regularity, and his knowledge of the details of its business was most minute and accurate, perhaps only surpassed by that of Dr. Carpenter, the late registrar. On the retirement of Dr. Foster, in 1864, he was appointed chairman of Convocation, and filled the post until last year, when he retired in consequence of his increasing deafness, and a liability to bronchitic attacks, which unfitted him for duties involving evening sittings in severe weather. He was also chairman of the Annual Committee, and rarely missed a meeting. The views of Convocation were always urged by him in the Senate, and members were quite sure that they would be pressed, even if personally he was not in entire sympathy with them. He was always, as he expressed it, the "devoted" servant of the graduates in Convocation. Dr. Storrar also served on the Endowed Schools Inquiry Commission, to which so many of our educational reforms are due, was a life governor of University College, and a governor of the Harpur Trust at Bedford, as the representative of the University of London. He was a man of fine presence and dignified manners; he entered zealously into all questions connected with the University, and fought for his views with all honesty and public spirit, and was always ready to hold out to his opponents the hand of friendship when the question was decided. His death has caused a void in the University ranks which will be long felt.

MR. C. LE VESCONTE GODFRAY.

THE island of Jersey has sustained a severe loss by the death of Mr. C. le V. Godfray, which took place on the 12th inst. Mr. Godfray was the son of a distinguished lawyer. He received his medical education at St. Bartholomew's Hospital, and became M.R.C.S. in 1859, and L.S.A. in 1860. Soon after he qualified he was appointed surgeon to the Jersey General Hospital, succeeding the late Mr. Jones, who achieved a European celebrity as one of the first advocates of excision of the knee-joint. Mr. Godfray had a very large general practice, but surgery was his favourite branch, and, with the only good surgical field in

Digitized by Google

the island at his command, he soon acquired the high reputation to which his experience and talents entitled him. He was a man of untiring energy, and worked hard at his profession—as hard as a man can work. If he had thought more of himself and less of others during the last year or two, possibly we might not have had so soon to deplore our loss. He was a man of quick, keen insight, seeming to seize the points of a case by instinct, and he had a promptitude and decision of manner and action which gained brusque, but this roughness of manner was often simply a confidence at once. His goodness and kindness of heart were over and over again felt by those to whom he not only gave advice, but often food and comforts. He shunned thanks; he was the sort of man who "did good by stealth, and blushed to find it fame." He will be greatly missed by his professional brethren, who were glad to avail themselves of his surgical skill and experience, as well as by his large circle of patients, and by the poor, who looked upon him as an unfailing resource in the hour of need.

Medical News.

UNIVERSITY OF OXFORD.—At a congregation held on the 11th inst., the degree of M.D. was conferred on

George Coates, Balliol.

UNIVERSITY OF CAMBRIDGE. — At a congregation held on the 11th inst., the degree of M.B. was conferred on

E. Collingwood Andrews and G. Darby Haviland, St. John's.

UNIVERSITY OF DUBLIN.—At a meeting of the Senate held last week the following degrees were conferred:—

BACHELOR IN MEDICINE.—P. S. Abraham, Alexander M'Neil D'Evelyn, Henry Cecil Earl, George Farls, Richard Bolton McCausland, Alfred Joseph McNally, George Burbidge Wite.

BACHELOR IN SURGERY.—Richard C. Bolton, Alexander McNeill D'Evelyn, Benjamin D. Dickson, William Ireland Donaldson, Henry Cecil Earl, Alexander Findlater, Robert Travers Lewis, Ross Vincent Beatty Smyth, James Christopher Weir.

DOCTOR IN MEDICINE.—P. Simon Abraham, Alexander Findlater, Thomas N. Flood, Thomas Richard Gillespie, H. Falconer Oldham, Ross Beatty Smyth.

COLLEGE OF PHYSICIANS IN IRELAND.—At the March examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—Louis Aloysius Byrne, William Robert Hall Harris, Alfred Lees Halkyard, Ernest Robert Howe, William Arthur Johnston, James Henry Maguire, Herbert Charles Mooney, Henry D'Arcy Power, Thomas Redmond, W. James Robinson, Frederick Osborne Smith, Augustus Tabuteau

MIDWIFERY.—Alfred Lees Halkyard, Ernest Robert Howe, Walter Kiddle, Herbert Charles Mooney, Thomas Redmond, William James Robinson, Frederick Smith, Augustus J. Tabuteau, Samuel Wilson.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 11th inst.:—

Benson, Henry Thomas, Aberynant, Llanidloes.
Clarke, William, St. Paul's-square, Burton-on-Trent.
Kearney, James, Clapham.
Swyer, Robert, Brick-lane, Bethnal-green.

PROFESSOR M. LEVI, Director of the Clinic for Children's Diseases in Florence, has died from apoplexy.

SANITARY INSTITUTE OF GREAT BRITAIN. — The Autumn Congress and Health Exhibition of this institute will be held in the city of York in September next.

THE *Spitalul* states that at the recent *concours* in Paris two Roumanian students gained posts as internes and six as externes.

AT a meeting of medical practitioners belonging to Ayrshire, on the 5th inst., it was resolved to form an Ayrshire Medical Club.

THE death is announced of Dr. Kazakivich, who had charge of one of the Red Cross hospitals in the Russo-Turkish war. He had written much on medical subjects and had translated Ludwig's Physiology into Russian.

AT the Wolverhampton police-court two county court bailiffs were fined 20*s.* and costs, or in default a month's imprisonment, for having seized, under a warrant of distraint, a quantity of bedding on which two children suffering from scarlet fever were lying. In spite of warnings they removed the bed to a neighbouring public-house, where it remained some days without being disinfected, and was then sold.

ON the 17th inst., Surgeon-Major Evatt, of the Army Medical Staff, delivered an address at Owens College on Ambulance Work and the Formation of a Volunteer Medical Staff Corps for the Manchester district.

SEVENTEEN persons, amongst whom was a clergyman, were fined ten shillings with the alternative of seven days imprisonment, at Leicester on the 15th inst., for failing to comply with the Vaccination Act. The number of defaulters in the town is reported to be 7000.

NEW HOSPITAL IN MEXICO.—*El Observador Médico* states that a new hospital has just been finished and opened in the Calle de Regina, Mexico, the cost of which has been defrayed by a legacy left by Señora de Beistigui. The medical officers appointed are Dr. Joaquin Vertiz and Dr. Ismael Prieto.

AT the annual court of trustees and governors of the York County Hospital on the 16th inst., it was unanimously resolved that Dr. Matterson, who had signified his intention to resign his position as physician to the institution, be requested to accept the office of honorary consulting physician.

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.—At a meeting of the Central Committee of the Association of Members of the Royal College of Surgeons, held on the 13th inst., a sub-committee was empowered to communicate with the Association of Fellows, upon the subjects of the Reform and the Charters of the College. At the same meeting a vote of condolence with Mrs. Cooper Forster was passed unanimously, in memory of the courteous manner in which the late President of the College received a deputation from the Association in January of last year.

THE DENBIGHSHIRE INFIRMARY.—Dr. Arthur E. Turnour, senior hon. medical officer to this institution, has given a munificent donation of £700 to the charity, "as a thank-offering to Almighty God for the recovery of his only daughter from a dangerous illness." The fund is to be applied to provide two free beds, the want of which in this hospital has been long felt. Dr. Turnour has rendered invaluable services to the infirmary for nearly forty years, and it was mainly through his instrumentality that the place has lately been reconstructed and a new wing added to it, at considerable cost.

CITY OF LONDON TRUSS SOCIETY.—The seventy-ninth annual festival dinner of this Society was held recently, upwards of 200 guests being present. The Lord Mayor, who presided, in proposing the toast of the evening referred to the increasing prosperity of the Society, and stated that the income from all sources for the past year amounted to upwards of £5000. In the course of the year the Society has been enabled to relieve upwards of 9000 sufferers, men, women, and children, this bringing up the total number relieved by the charity, since its foundation in 1807, to 413,316. During the evening subscriptions amounting to £500 were announced.

THE LEVEE.—At the levée held at St. James's Palace on the 15th inst. by H.R.H. the Prince of Wales on behalf of Her Majesty, presentations of the following members of the medical profession were made: Surgeon Henry M. Adamson, Brigade Surgeon J. E. T. Aitchison, Surgeon-Major Joseph A'Hearne, Surgeon J. B. Buchanan, Surgeon H. Herbert Brown, Dr. Robert Barnes, Surgeon Waller C. Beevor, Dr. R. W. Burnet, Surgeon-Command. James Cantlie, Surgeon William A. Carte, Surgeon T. Herbert Corkery, Surgeon W. R. Crooke, Surgeon Horace Cocks, Surgeon A. Rea Edwards, Surgeon E. H. Fenn, Surgeon Richard E. George, Brigade Surgeon G. C. Gribbon, Surgeon J. P. S. Hayes, Surgeon F. W. Hennessy, Surgeon Stanley J. W. Hayman, Surgeon John Kearney, Surgeon Arthur Kennedy, Surgeon H. W. M. Kendall, Surgeon E. H. Locker, Surgeon W. J. Lee, Surgeon-Major A. B. R. Myers, Surgeon C. H. Melville, Surgeon Bernard L. Mills, Surgeon Langton G. Mumby, Surgeon-Major James Magill, Surgeon H. M. Ramsay, Surgeon C. Alan Renny, Surgeon Hugh Rayner, Dr. Argyll Robertson, Surgeon W. E. Raw, Surgeon J. E. Squire, Surgeon F. L. Stephenson, Surgeon Whitley Stokes, Surgeon Frederick Skerrett, Surgeon Francis A. Saw, Surgeon Walter Squire, Surgeon Herman Thiele, Dr. John Tanner, Surgeon J. B. Wilson, Surgeon H. R. Woolbert, Surgeon C. L. Walsh, and Surgeon M. T. Yarr. The following, amongst others, attended the levée: Sir William Bowman, Bart., Sir Guyer Hunter, and Surgeon-Major R. Boustead.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ALLINSON, H. CALTHORP, M.R.C.S., L.S.A.Lond., has been appointed Honorary Surgeon to the West Norfolk and Lynn Hospital, vice Wilson, resigned.

CUMBERBATCH, A. E., F.R.C.S., has been appointed Aural Surgeon to the National Hospital for the Paralysed and Epileptic.

ELLISON, WILLIAM A., M.A., M.B.Oxon., L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Eton District of the Eton Union

EWART, CHARLES, M.B., C.M., has been appointed House-Surgeon to the Royal Hants County Hospital, Winchester.

FORSTER, T. F., M.R.C.S., L.R.C.P.Lond., L.S.A.Lond., has been appointed Senior House-Surgeon to the Carlisle Dispensary, vice J. Macdonald, M.B., resigned.

GOULD, ERNEST E., L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the First District of the Hailsham Union.

HARRIES, ARTHUR J., M.D., M.R.C.S. (late Senior Assistant-Physician), has been elected Physician to St. John's Hospital for Diseases of the Skin, vice James Startin.

HEYWOOD, T. WALMSLEY, M.R.C.S., L.K.Q.C.P.I., has been appointed House-Surgeon to the District Infirmary, Ashton-under-Lyne, vice H. Payne, M.D., resigned.

LAWTON, HERBERT A., L.R.C.P.Lond., M.R.C.S., M. and L.S.A.Lond., has been appointed Medical Officer of Health for the Borough and Port of Poole.

MACDONALD, JAMES, M.A., M.B., C.M.Ed., has been appointed Medical Officer for the Stanwix District of the Carlisle Union.

MARSH, N. PERCY, M.B.Lond., M.R.C.S., has been appointed Assistant Honorary Medical Officer to the Infirmary for Children, Liverpool.

MAYNARD, FREDERIC P., M.B., M.R.C.S., L.R.C.P.Lond., has been appointed House-Surgeon to the Infirmary, Newcastle-upon-Tyne, vice J. W. Bidley, M.B., M.R.C.S., resigned.

PAIN, TERTIUS D'OYLEY, L.S.A.Lond., has been appointed Medical Officer for the Kentchurch District and the Workhouse of the Dore Union.

SCHOFIELD, GERALD, M.R.C.S., L.R.C.P.Lond., has been appointed House-Surgeon to the Yarmouth Hospital.

SEARLE, R. BURFORD, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Second District of the Penzance Union.

Births, Marriages, and Deaths.

BIRTHS.

BATTISCOMBE.—On the 8th inst., at St. Mary Cray, Kent, the wife of C. G. Battiscombe, M.B., C.M., of a son.

BROWN.—On the 13th inst., at Bartholomew-road, N.W., the wife of Andrew Brown, M.D., M.R.C.P.E., of a son.

COLTART.—On the 9th inst., at Ashbourne House, Epsom, the wife of William Wilson Coltart, L.R.C.P.Lond., M.R.C.S., of a daughter.

HARRISON.—On the 16th inst., at Sandringham-gardens, Ealing, W., the wife of R. Charlton Harrison, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., of a daughter.

MURRAY.—On the 12th inst., at Gloucester-place, Portman-square, the wife of Charles Stormont Murray, L.R.C.S., of a son.

STEPHENS.—On the 10th inst., at Brook-street, W., the wife of S. Sanders Stephens, M.R.C.S., of a daughter.

WHITE.—On the 11th inst., at Sliema, Malta, the wife of Staff-Surgeon W. R. White, R.N., H.M.S. *Sylvia*, of a son.

WOOD.—On January 22nd, at Leighton House, Stanmore, Sydney, the wife of W. B. Ramsden Wood, M.D., of a son.

MARRIAGES.

CLATWORTHY — HOPE.—On the 9th inst., at Holy Trinity Church, Dartford, Herbert Clatworthy, M.R.C.S., L.S.A.Lond., son of E. Clatworthy, Esq., late of H.M. Dockyard, Chatham, to Alice, daughter of the late Frederick Hope, of Kensington.

HANKINS—FULLERTON.—On January 20th, at Sydney, N.S.W., George Thomas Hankins, M.R.C.S., of Sydney, formerly of Clapham, London, elder son of the late Thomas Hankins, M.R.C.S., of Clapham, to Janet Christina, third daughter of the Rev. James Fullerton, LL.D., of Sydney, N.S.W.

DEATHS.

COURTENAY.—On the 15th inst., at Chandos-street, Cavendish-square, Francis Burdett Courtenay, M.R.C.S., in his 76th year.

FALWASSER.—On the 4th ult., at Neemuch, Central India, Francis Falwasser, F.R.C.S., Surgeon-Major, A.M.D.

JOHNSTONE.—On the 11th inst. (after four days' illness, of Bright's disease, pyæmia, and peritonitis), at Calcutta, George Hastings Johnstone, F.R.C.S.Eng., aged 48.

MAGENISS.—On the 1st inst., at the Bolton Hotel, Peter Mageniss, M.D., Consulting Physician to the Italian Hospital, aged 73.

SMART.—On the 16th inst., at Argyll Lodge, Amhurst-park, London, N., James Smart, F.R.C.S., aged 66.

WEBER.—On the 10th inst., at 44, Green-street, Grosvenor-square, Frederic Weber, M.D., F.R.C.P., in his 78th year.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, March 22.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 3 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Wm. Arthur Brailey: The Muscles and Fasciæ of the Orbit.

SOCIETY OF ARTS.—8 P.M. Mr. Boverton Redwood; Petroleum and its Products (Cantor Lecture).

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Bowreman Jessett: Two cases of Amputation of the Penis by Mr. Pearce Gould's Modification of Thiersch's Operation for Epithelioma.—Mr. A. Pearce Gould: Notes of a case of Alveolar Abscess, causing Death.

Tuesday, March 23.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee: The Function of Circulation.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Mr. S. J. Sharkey: On Spasm in Chronic Nerve Disease (Gulstonian Lecture).

SOCIETY OF ARTS.—8 P.M. Mr. Alexander Begg: Canada and its National Highway.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. Hebb: Case of Tuberculosis of the Skin.—Dr. Theodore Williams and Mr. Godlee: Two cases of Bronchiectasis treated by Paracentesis, with Remarks on the Mode of Operation.

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8.30 P.M. Capt. C. R. Conder: Present Condition of the Bechuana, Koranna, and Matabele Tribes.

Wednesday, March 24.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

A RUSSIAN PRACTITIONER PUNISHED FOR REFUSAL TO ATTEND.

A FOREIGN correspondent, referring to an annotation which appeared in our columns on the 6th ult. on the subject of a practitioner being punished for refusal to attend a patient, calls attention to the consequences of such a condemnation to the defendant. Until the termination of the process he was prevented from leaving his dwelling-house; and as the lawsuit has lasted fifteen months (and, it appears, is not likely to be speedily concluded), all professional occupation, excepting in the cases of patients who are well enough to visit him, is impossible. He has also been prevented from going to a watering-place to which he has of late years been in the habit of repairing for his health's sake, and this prohibition will endure until the suit is ended. Refusal to attend a patient in Russia evidently means ruin to the luckless practitioner.

Edina.—Cocaine has been favourably reported on as a remedy in sea-sickness. But its efficacy is, we believe, not invariable.

"THE USE OF COCAINE IN OPERATIONS FOR PILES."

To the Editor of THE LANCET.

SIR,—Will you permit me to inform Dr. Pritchard, who wrote on the above subject in your last issue (p. 527), that I have for some time past used cocaine as a local anæsthetic for the removal of piles in suitable cases, having performed two operations prior to the appearance of the annotation in your issue of Jan. 31st, 1885 (p. 220), on Mr. Swinford Edwards' case. I make use of the words "suitable cases" advisedly, as I have found that the operation can only be performed painlessly by the use of cocaine when the pile is situated close to the margin of the anus, and not involving too great an extent of skin. I apply a 20 per cent. solution first around the mass, and afterwards inject hypodermically a few drops into its substance.

May I also be allowed to inform your correspondent that I claim to be the inventor of the clamp with which he has associated Mr. Downes' name (see correspondence between Mr. Downes and myself in the *British Medical Journal*, vol. i., 1885, pp. 703, 974).

I am, Sir, yours truly,

Baron's-court, S.W., March 15th, 1886. R. FITZROY BENHAM.

WRY-NECK.

To the Editor of THE LANCET.

SIR,—I should be glad if any of your readers could give me a hint on the treatment of a case of wry-neck. I have already tried hypodermic injections of morphia, liniments of iodine, belladonna, aconite, turpentine and soap, blisters, massage, together with the internal administration of iodide of potash, iron, quinine, nux vomica, and belladonna; but all without avail. Indeed, the case seems to be getting worse.

I am, Sir, your obedient servant,

Elgin-road, W., Feb. 23rd, 1886. JOHN BEATTIE CROZIER, M.B.

THE INSANE POPULATION OF VICTORIA.

FROM the report of Dr. T. T. Dick, Inspector of Lunatic Asylums in Victoria, for the year 1884, which has just been published, it appears that during the year the number of persons officially recognised as insane increased by 19, or from 3209 to 3228. During the past five years the average annual increase has been 45, as compared with 129 per annum during the preceding ten years. Of the 3228, 1749 were males and 1479 females. In the thirty-seven years ending with 1884, 9251 males and 6478 females, or 15,729 in all, have been admitted into the public lunatic asylums, 914 of these being readmissions. The percentage of deaths on the average numbers resident seems to be decreasing. In the three years 1882-4 inclusive it was in each year under 7; but in the preceding fourteen years there were only four years in which the percentage was under 7. The total receipts of the department during 1884 amounted to £6744, the expenditure being £96,225. Of the receipts, £5667 was collected by the Master in Lunacy for the maintenance of patients from their relatives and representatives.

A Junior.—Wilson Fox, Pavy.

"COLOUR-BLINDNESS AMONG MEDICAL MEN."

To the Editor of THE LANCET.

SIR,—The question raised by your correspondent, Mr. Piesse, in your last issue is a somewhat difficult one to answer. There can be no doubt that in medico-legal practice colour-blindness would form an obstacle which might prove insuperable. It is not the lot of every practitioner, however, to find himself in the witness-box, and the mere possibility of his being dragged into a court of law should, I think, weigh but lightly in considering whether a colour-blind man is justified in adopting medicine as his profession. As regards general practice, I cannot imagine that colour-blindness would really be a serious bar to success. Pitting a physically sound man against a physically unsound one, the advantage would, of course, appear to be, *ceteris paribus*, in favour of the sound one. The examples given by Mr. Piesse as possible points of difficulty need not, I think, be made much of. The diagnosis of iritis certainly does not rest so much on the colour of the iris as on the concomitant symptoms, such as ciliary injection, thickening of pupillary margin, contraction of pupil, and, under atropine, irregular dilatation, to say nothing of synechiæ, if they exist. Glaucoma is not diagnosed simply by the greenish colour to which the disease owes its name, but rather to the tension of the globe, the condition of the disc and vessels, the appearance of the capsule of Tenon, the acuteness of vision, the well-known rainbow colours seen by the patient, the pain and the contracting field of vision, &c. Again, in the exanthems the colour of the rash is not so important a feature in diagnosis as the history of the attack, the period of incubation, the temperature of the patient, and the form and situation of the eruption. Have we not "scarlatina sine eruptione"? Nevertheless, there are drawbacks resulting from colour-blindness which cannot be disguised. Whenever the safety or well-being of a number of persons depends on the perfect vision of one individual, it should be ascertained beyond doubt that the individual in question is not colour-blind. This may be the case with those who enter the army and navy. From what I know of the tests to which candidates for the services are subjected, I am of opinion that the vision is not examined sufficiently carefully, and many men are passed whose sight is far from satisfactory. The ordinary coloured wools would, I feel sure, reveal many cases of colour-blindness in military and naval men, if carefully used. The commonest confusion colours are reds and greens. These happen to be the very colours used for signals in the navy and elsewhere. The uniforms of most of our soldiers are scarlet; and yet many men in our ranks might say they were green! It has been my lot to meet with two railway officials, practically concerned with traffic management, who confused reds with greens. The danger to which passengers are exposed if colour-blindness be overlooked in railway *employés* is painfully obvious. Considering all things, therefore, it seems to me that a general practitioner may get on very comfortably under ordinary circumstances notwithstanding colour-blindness, whilst a medical officer carrying out special duties requiring more perfect vision may fail to succeed.—I am, Sir, yours truly,

A. ST. CLAIR BUXTON, F.R.C.S.,
Assistant-Surgeon to the Western Ophthalmic Hospital.

Orchard-street, W., March 15th, 1886.

ON A METHOD OF CONTROLLING BLEEDING DURING COMPLETE OR PARTIAL EXCISION OF THE TONGUE.

To the Editor of THE LANCET.

SIR,—Would you allow me to make a suggestion which may be of use to Mr. Jordan Lloyd and others who may adopt his method of removing the tongue, as described by him in a recent number of your valuable journal. By Mr. Lloyd's alternative way of introducing the needle the second time, directly through the skin, there is, as he says, danger of causing sloughing. This danger may be obviated by placing the half of an ordinary cork, split in its long diameter, upon the skin between the punctures, and then tying the ligature over it. In this manner an elastic pad is produced, which will effectually protect the skin from the pressure of the whipcord ligature, and will furnish a very convenient support against which to compress the lingual vessels.

I am, Sir, yours truly,

Larnaca, Cyprus, Feb. 15th, 1886. J. G. LAFFAN, Colonial Surgeon.

CHRONIC URTICARIA.

DR. J. BRISBANE, of 21, Park-road, Regent's-park, writes to thank the many gentlemen who have so kindly communicated with him regarding his case of chronic urticaria. It would be too great a task to reply to each individually; he therefore trusts that they will all accept this acknowledgment. Dr. Brisbane adds that the rash had spread over the whole body, and the irritation had become agonising, the patient saying that the pain he suffered during the continuance of the rheumatism was more tolerable than the fearful itching and burning of this rash. Under the use of Donovan's solution the patient improved for a time, the rash nearly disappearing; but it soon returned, and has since been rebellious to all treatment. Dr. Colcott Fox kindly saw the case, and expressed the opinion, as had Dr. Crocker, that it was one of "dermatitis herpetiformis," as described by Dr. Duhring of Philadelphia. At his suggestion, the patient was brought before the Dermatological Society on March 10th, when those present concurred in this diagnosis. Dr. Brisbane himself has no doubt that the case is one identical with those described by Dr. Duhring under the title "dermatitis herpetiformis (erythematosa)," but regrets that Dr. Duhring does not give a single suggestion as to treatment.

T. S. H.—Office of the Crown Agents for the Colonies, Downing-street.

LONDON HOSPITAL MEDICAL COLLEGE.

To the Editor of THE LANCET.

SIR,—The account of the ceremony of laying the corner-stone of the new buildings in connexion with the London Hospital Medical College contained in THE LANCET last week assigns so subordinate a position to the staff of the hospital that it might be thought that the medical school is entirely under lay management, that the College is being enlarged at the sole cost of the governors of the hospital, and that the staff were present merely as spectators of a function with which they had no particular concern. For this reason, and for the sake of an accurate record, some amplification of the account is rendered desirable.

It had been appropriately arranged in the authorised programme that the ceremony should be opened by an address to the visitors by Sir Andrew Clark, as the representative of the staff. He was unable to attend, and at the last moment the duty of inaugurating the proceedings suddenly devolved upon myself, as the senior member of the staff actually present. In the course of my remarks I pointed out that the original medical school buildings at the east end of the hospital were erected in 1783–85 by the medical staff, assisted to some extent by subscriptions from individual governors and friends of the hospital. In 1854 the fabric which is now in great measure disappearing, to be replaced by an enlarged college, was erected, at a cost of more than £10,000, by the governors, who required the old school buildings for absorption into an expanding hospital. Since then two enlargements, one in 1871 and the other in 1879, have taken place, and in each instance by means of money borrowed by the medical council of the school from the governors, and repaid out of the students' fees. A certain amount of the sum required for the first of these two enlargements was handsomely remitted by the house committee. The present enlargement is being carried out in a similar manner. The sum of £15,000 has been lent to the medical council of the school by the house committee and governors of the hospital, and the interest will be paid in perpetuity by way of rent, and as a first charge on the fees received from students. In every instance the erection of school buildings has resulted from the urgent representations of the staff and lecturers to the governing body of the hospital, and, save in 1854, when a new and more expensive edifice was given in exchange for the old school, the sinews of war have been guaranteed or provided by the staff and lecturers. The school, however, has been greatly benefited by the cordial co-operation and liberality of the members of the house committee. After giving the main details of the new building embodied in your annotation, I alluded to the present government of the school by a conjoint board, consisting of an equal number of representatives of the house committee and the medical council. The happy conjunction of these two bodies, working formerly on parallel lines which do not meet, has ensured a unity of design and action which were unavoidably absent under the old, but by no means inactive or inefficient, management. After a brief service of prayer, conducted by the chaplain, Mr. Valentine, and the laying of the stone by Mrs. Thompson, the meeting was briefly addressed in congratulatory terms by Mr. Thompson (the chairman of the College board), by Mr. Carr-Gomm (the chairman of the house committee), and by Mr. Frederick Treves in response to a call from the students, who were present in force.

I am, Sir, yours faithfully,

Finsbury-square, E.C., March 15th, 1886. WALTER RIVINGTON.

PRACTICE AT THE CAPE.

To the Editor of THE LANCET.

SIR,—I should feel much obliged if any of your readers could give me some information about practice in South Africa. What parts of the colony afford the best openings at present, and what capital would be necessary for the purpose of starting in practice? Are drugs easily obtainable in the colony? Would it be advisable to take out a supply? In what part would the climate be most suitable for a surgeon whose lungs are slightly affected? Any other information will be most thankfully received by

Yours obediently,

March 2nd, 1886. A CONSTANT READER.

PAPAL AND TALMUDICAL OPINIONS ON CRANIOTOMY.

A SHORT time ago it was announced that the question of craniotomy had been carefully discussed by the Inquisitors-General at Rome, who voted unanimously against the practice on the ground that the taking of a human life could not possibly be justifiable, except as a legalised punishment for crime. This finding was formally referred to the Pope, who ratified and promulgated it. Dr. Mielziner, Professor at the Hebrew College, Cincinnati, has, thinking it to be of interest, recently published the Rabbinical view on this question, which is as follows:—"In Mishna *Oholoth*, vii. 6, the undisputed decision is laid down that 'in case of a dangerous parturition it is justifiable to kill the unborn infant in order to save the mother, as her life precedes its life.' Such operation is, however, not permitted after the infant has already been partially born, as in the latter case the maxim applies that one human life must not be set aside on account of another. In his commentary on Tamid. Sanhedrin 72*b*, where this Mishna is quoted, *Rashi* explains the reason of the distinction between these two cases that the unborn infant is not yet a *distinct personality* with an *independent* life, hence the duty of saving the mother's life is to prevail, while in the second case its individuality is established, hence the legal principle must apply that one life must not be destroyed to save another. The authoritative codes of Maimonides (Hilchoth Rotzeach u Shemirath Nephesh I. 9), as well as of R. Joseph Caro (Choshen Mishpat 425, 2), adopted the decision of the Mishna as the rule of Jewish law." It must be conceded that the Rabbinical view in this case is much more in accordance with common sense and with the highest regard for the sanctity of human life than the Papal opinion.

M.D., F.R.C.S.—1. We are not aware of such an instance.—2. No.

"THE NEUROTIC TREATMENT OF CATARRH."

To the Editor of THE LANCET.

SIR,—In reference to Dr. Lees' communication on the neurotic treatment of catarrh, in your issue of Feb. 27th, I would like to emphasise the fact that in many cases the disease may be promptly checked by local remedies; but the one I have found to be the most efficient he has omitted to mention. Personal experience, extending now over several years, has taught me that when the catarrh is the result of an exposure to a cold or east wind (less frequently, perhaps, when due to a general chill), it can always be limited to the nostrils, and cured in a few hours, by the occasional inhalation of a strong solution of ammonia. I have tried many other reputed and well-known remedies, but I have found none of them so useful, convenient, and satisfactory as this. All that is necessary is to sniff from a small bottle containing about a drachm of the liquid and repeat the dose whenever the return of the watery flux indicates that the effect of the former inspiration is passing off. The frequency and number of the inhalations will be, of course, inversely proportionate to the amount and strength of the vapour drawn into the nostrils. As the bottle can easily be carried in the pocket, it is also obvious that such a remedy gives the minimum amount of trouble, and can be used anywhere, even unobserved. I need only add that when prescribing for others I combine the ammonia with compound tincture of benzoin or other aromatics, and that I should always prefer quinine to bromide of potassium for internal administration.

I am, Sir, yours truly,

Tunbridge Wells, March 8th, 1886. G. ABBOTT.

To the Editor of THE LANCET.

SIR,—I read with much interest Dr. Lees' paper in THE LANCET of Feb. 27th, more particularly as I have been in the habit of using one of the drugs which he recommends—viz., belladonna—for the treatment of catarrh in my own person for more than five years, having been led to do so by the perusal of a letter in your columns in which its virtues as a remedy for catarrh were extolled. My object in troubling you with this communication is to point out that, as far as the writer's personal experience goes, belladonna is a sure and certain remedy for catarrh when taken in the initial stage—i.e., when a general chilliness of the surface and a dryness of the nasal mucous membrane are felt. Taken thus promptly, a dose of from twenty-five to thirty minims of tincture of belladonna has never yet failed to check an attack, and consequently to anticipate and prevent the sneezing, nose-weeping, and other disagreeable concomitants of "a cold in the head."

I am, Sir, yours truly,

Watton, March 3rd, 1886. H. MALLINS, M.D.

THE CANTANI TREATMENT OF PHTHISIS.

Æsculapius.—From a culture of what he calls the "bacterium termo" in sterilised broth Dr. Cantani obtains a liquid which he causes to be inhaled before the patient's mouth. In the struggle for existence between the "bacterium termo" and the bacillus of Koch, the latter, he says, succumbs. This, Dr. Cantani avers, he had ascertained experimentally by the commingling of the two cultures, and on applying the principle to the treatment of pulmonary phthisis he has had quite satisfactory results in three cases in his clinique. The cure, he adds, is effected in less than three months. A treatise on the subject, similar to his well-known one on "Hypodermoclysis," is anxiously expected from the brilliant Neapolitan therapeutist.

Dr. N. E. Davies' paper is marked for insertion.

DIPHTHERIA AND PIGEON-KEEPING.

AT a recent meeting of the Anatomical and Pathological Society of Brussels, M. Destrée called the attention of the members to the fact that cases of croup had been greatly and steadily on the increase in Brussels, so that croup and diphtheria were now endemic there, and he ventured to suggest that there might be some connexion between the keeping of pigeons and the occurrence of these diseases. He pointed out that Emmeriels of Munich had found the microbe of diphtheria in these birds, and he himself had met with three cases of croup in families where pigeons were kept, in all of which cases signs of the disease had appeared in the pigeons. M. Destrée hoped that members would bear this matter in mind, in order that it might be further elucidated.

Mr. R. Jelly.—Fayrer, Tropical Dysentery and Diarrhœa and other Diseases, 1881; Maclean, Articles in Reynolds' System of Medicine, vol. ii.

BATH CHAIRS AT HASTINGS AND ST. LEONARDS.

To the Editor of THE LANCET.

SIR,—The attention of the Hastings Town Council has just been called to a letter on the above subject which appeared in your issue of Jan. 16th last; and as some of the statements made by the writer are calculated to produce a misleading impression in the minds of those who are unacquainted with the facts of the case, I have been directed to ask you to be good enough to insert this explanation in your next issue.

In the first place, the drawing of wheeled carriages of any description whatever on foot pavements, so as to be an obstruction or annoyance to passengers, is prohibited by statute law (the Towns Police Clauses Act, 1847), which is in force in every town in England, and which may be put into operation by "any person aggrieved," as well as by the police authorities; so that it is obvious that neither the Council nor the superintendent of police has any power to give "permission" for Bath chairs to be drawn along the foot pavement. At the same time there is not the slightest probability that any action would be taken by the police authorities in a case in which the foot pavement was being made use of in consequence of the afflicted state, whether owing to a nervous or spinal complaint or otherwise, of the occupant of a Bath chair, unless under very exceptional circumstances, as the crowded condition or narrowness of the foot pavement.

It has been the earnest desire of the Town Council to afford every possible facility and comfort to the numerous invalids who resort to the town for the benefit of their health. They have licensed over 100 Bath chairs, and have had the Parade, for a length of upwards of a mile and a half, paved with asphalte and tar paving, upon which Bath chairs are allowed to be drawn practically without restriction. I may just mention that nearly, if not quite all, the Bath chairs here are provided with indiarubber tyres, which have the effect of materially reducing any jolting motion when they are drawn on the roadway.

I remain, Sir, yours truly,

Hastings, March, 1886. GEO. MEADOWS, Town Clerk.

Student.—Medical etiquette abroad cannot always be made subservient to the strict rules which obtain in the United Kingdom.

"SCARLET HOSIERY."

To the Editor of THE LANCET.

SIR,—In answer to Mr. Holmes' inquiry in your last issue (p. 526), I beg to say that the symptoms in the case of my friend (Mr. Luff of St. Mary's Hospital) were swelling, inflammation, and pain in two or three toes, accompanied a day or two later by swelling, inflammation, and pain in one of the lower vertical inguinal glands.

I am, Sir, yours obediently,

Marylebone-road, N.W., March 16th, 1886. JOHN WOODLAND.

ATROPINE REACTIONS.

MORE than a year ago Mr. Gerrard demonstrated that atropine and other mydriatic alkaloids were so powerfully alkaline as to precipitate mercury from the solution of mercuric chloride. Flückiger has confirmed his results, but has asserted that atropine does not blacken calomel—mercurous chloride. Mr. Gerrard has brought forward, in the *Pharmaceutical Journal*, evidence to show that mercurous chloride is blackened by atropine.

Surgeon-Major Staples.—In an early number.

Gulstonian Lectures
ON
SPASM IN CHRONIC NERVE DISEASE.

Delivered at the Royal College of Physicians of London, March, 1886.

By SEYMOUR J. SHARKEY, M.B., F.R.C.P.,
ASSISTANT-PHYSICIAN AND JOINT-LECTURER ON PATHOLOGY AT ST. THOMAS'S HOSPITAL.

LECTURE I.

(*Concluded from page 535.*)

IN THE LANCET of September 27th, 1884, my colleague, Dr. Reid, published his "Observations on the Relation of the Principal Fissures and Convolutions of the Cerebrum to the Outer Surface of the Scalp." Before the patient left the Home Dr. Edmunds got Dr. Reid's assistance in determining the position of the lesion by surface markings. The boy's head was shaved, and the fissures marked upon the smooth surface, and the opening in the skull was found to be half an inch in front of the middle of the fissure of Rolando. But as it was known that the disease extended backwards along the dura mater for a short distance behind the opening, the conclusion drawn was that the middle of the ascending frontal and ascending parietal convolutions was the part affected. The account I am about to give of the post-mortem examination shows how accurate this localisation was. The patient returned to the Home on Sept. 11th, 1885, looking very ill and emaciated, and with a sinus on the right side and back of the neck, connected with an evident angular curvature of the spine. His right

FIG. 8.

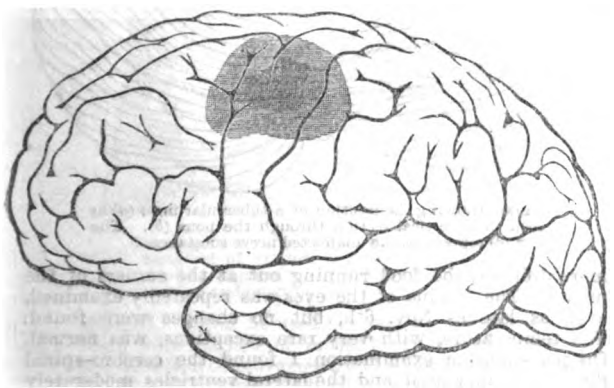

Diagram shewing the position of the cortical lesion. The lighter shading represents the area of adhesion between the dura mater and the arachnoid; the darker area the superficial destruction of the cortex.

arm was flexed at the elbow, and could not be completely extended. He died of exhaustion on Nov. 12th, 1885, the end being accelerated by diarrhœa, which was scarcely controllable. At the post-mortem examination relics of past peritonitis were found, and old and recent tubercular affection of the lungs. There was a chronic abscess in relation with caries of the lower cervical vertebræ, the disease which had produced the angular curvature. There was chronic thickening of the membranes of the cord in this region, but no evident disease of the cord itself. Dr. Edmunds was good enough to hand over to me the brain and spinal cord for careful examination. The following is an account of the condition of things which I found, after hardening the specimens in spirit. The dura mater, which was thickened and adherent over a portion of the left parietal convolutions, was gently peeled off, and that part of the cortex which was so far invaded by disease that it could not be separated from the dura mater, but was torn during its removal, is marked in Fig. 8. The lighter shading represents very slight superficial abrasion, and the darker central part shows where the disease had sunk deeper into the grey matter. The area marked in the figure measured an inch and a half vertically, and the same horizontally. The position which it occupied was the upper half of the middle third of the ascending frontal and parietal convolutions, together with a small portion of the posterior extremity of the middle and of the superior frontal convolutions. On making a horizontal section through the basal ganglia and the internal capsule, a slight discolouration could be seen in the latter just behind its knee. On making a vertical section through the ascending frontal convolution, and traversing the centre of the diseased area, the destruction of cortex was seen to be quite superficial, and no degeneration was made out in the subcortical white matter. The cord was examined high up in the cervical region, above the seat of the chronic meningitis which resulted from the disease of the cervical vertebræ. The sections show that the right half is much smaller than the left, the diminution in size being apparent, not only in the lateral column, but also in the column of Türck. Under the microscope, the connective tissue in the right lateral column is seen to be denser than that in the left, and the nerve fibres appear to be here and there less numerous.

Hospitals where old people congregate afford the best opportunities for post-mortem examination of persons whose brain is the seat of softening originating long before death. Charcot has given his experience at the Salpêtrière, and he says:[1] "In these cases the lesion presented itself under the form of yellow softening (*plaques jaunes*), more or less extensive in area, involving, to a variable depth, the subjacent white matter, and occupying the most diverse regions of the surface of the hemisphere. It is expressly mentioned in all the observations that the softening had not affected the central masses: optic thalami, caudate and lenticular nuclei, and internal capsule. My observations may be divided into two groups. The first includes the cases in which permanent hemiplegia had not existed during life, and in which secondary degeneration was found at the necropsy to be absent. In all, the convolutions supplied by the Sylvian artery, and particularly the ascending frontal and parietal, remained intact. The yellow softening was situated in one of the following regions—namely, some part of the sphenoidal lobes, the lobulus quadratus, the cuneus, one or both occipital lobes in their entirety, some part of the anterior two-thirds of the frontal lobes. In all cases of the second group there had been, on the other hand, permanent hemiplegia and well-marked secondary sclerosis. The feature common to these cases is that the lesions invariably involved, to a greater or less extent, one or other of the ascending frontal and parietal convolutions, principally in their upper half, and often both at the same time. In addition, the regions nearest to the frontal and parietal convolutions were very frequently involved."

In most instances, destruction of a portion of the pyramidal tract on one side gives rise to paralysis and spasm on the opposite side of the body only; but occasionally spasm of the muscles on the same side as the lesion follows later in the history of the case. This is probably due to sclerosis appearing in the opposite lateral column, as Pitres has shown that it often does; and Mr. Sherrington has shown that it occurs in dogs which have had one pyramidal tract experimentally injured. But although this is probably the cause of most cases of bilateral spasm from unilateral lesion, the possibility of the presence of a bilateral lesion must be borne in mind. In the *Revue de Médecine* of May, 1883, Emile Demange records a case of the kind where a bilateral lesion was found in the brain post mortem.

Leaving affections of the cortical and subcortical portions of the pyramidal tract, let us pass to a consideration of the symptoms which accompany diseases of it as it traverses the basal ganglia, crura cerebri, pons Varolii, and medulla oblongata. It is needless, before an audience like the present, to recount cases of hemiplegia followed by rigidity, which result from destruction of the internal capsule by hæmorrhage or softening. Such examples of disease are of common occurrence, and well known to all. I shall rather give an account of a series of cases which are less frequently met with, and which made a considerable impression upon me from two points of view:—1. Because they seem to

throw considerable light on the rigidity and tetanic seizures which are observed in tumours of the cerebellum. 2. Because I failed to recognise the position of the disease in the brain during life, though a reconsideration of the symptoms leads me to think that others might have succeeded.

Case in which a Tubercular Mass occupied both Optic Thalami, producing Paralysis, Tumours, and Rigidity of the Limbs.—F. P——, aged four, was admitted into St. Thomas's Hospital under Mr. Sydney Jones, in August, 1878, and on the 22nd of the following October excision of the left astragalus was performed. The child did very well and was bright and playful until January 28th, 1879, when tremors of the left arm and leg were noticed. They were rhythmical to-and-fro movements, of short excursion, occurring only when the limbs were used voluntarily. There was very little loss of power, no affection of speech, deglutition, or respiration; and the tongue, face, and eyes all moved normally. On March 5th the child was still bright and lively, though pale; and it was noticed that the tremors were more marked on some days than on others. The left side of the face and the right hand had also begun to show similar tremors when used. The patient was sent out of the hospital, but was readmitted under Mr. Sydney Jones on July 8th, 1879, because the ankle and general condition were said to be worse. He had gone gradually downhill, had become very drowsy, passed his evacuations in bed, and was more tremulous. On readmission his face was pale and a large dilated vein coursed transversely across the right upper eyelid. He was always asleep unless roused, and would even fall asleep while eating ravenously. His appetite was good, but he never asked for food. He complained of no pain, but appeared to have general hyperæsthesia of the skin. He was very irritable and peevish, crying out loudly when disturbed or contradicted. There were now rhythmical tremors of the right upper extremity, which were excited by voluntary efforts, and resembled those which used to affect the left side; the latter had ceased and given place to rigid contraction. The elbow was flexed, and the hand clenched so tightly that the finger-nails had produced ulcers in the palm. The hand was pronated, and the rigidity was constant. The mouth appeared natural when at rest, but when the child laughed or cried it was drawn up to the right. There was no squint; the pupils were large and acted to light. The tongue was protruded straight, but was tremulous, and speech was slow. There was no deafness, but the ophthalmoscope revealed double optic neuritis. There was no vomiting or dysphagia; the bowels were very confined, and the evacuations passed in bed. The pulse was 114, respiration 24, and the temperature varied between 99·4° and 101° F. The viscera appeared to be healthy. Until Oct. 8th the symptoms already described became worse. The right hand, arm, and leg trembled violently when used, and the left leg became perfectly rigid. The patient was very drowsy, and seemed to suffer from some headache; but he was never sick, and his appetite was good. His head was slightly retracted. On Oct. 8th he seemed much worse; he vomited three times, took his food badly, and the temperature rose to 103·2°. Subsequently he became more drowsy, his right eyelid drooped, the pupils became unequal, and repeated attacks of general rigidity (sometimes accompanied with foaming at the mouth) supervened, and he died on Oct. 15th. On post-mortem examination, I found an acute recent basilar meningitis. Besides this affection, which was no doubt the immediate cause of death, a large caseous tubercular mass was seen, involving both optic thalami and almost completely obliterating the third ventricle (Fig. 9). The right optic thalamus was the more completely disorganised of the two. The specimen which I now show was hardened in alcohol, and on section it was then seen that on the left side the internal capsule, though pressed upon by the new growth, was clearly defined and looked fairly natural, while that on the right was unrecognisable. The tubercular mass was confined to the optic thalami, and did not involve either nucleus of the corpus striatum. A very small caseous tubercle was also found on the internal aspect of the left occipital lobe, but the rest of the organs were healthy.

It is well known that diseases of the optic thalami and corpora striata are not accompanied by any such symptoms as were present in this case, unless the internal capsule is involved, and the paralysis, tremors, and rigidity of limbs must be attributed to the invasion of this strand of fibres, proceeding from the motor convolutions; while the convulsions of the last week were the result of the recent meningitis. (This case has been already recorded by Dr. Bristowe, in *Brain*, vol. vi., p. 167.)

Case of large Caseous Tubercle of the Pons Varolii, producing Persistent Rigidity of the Neck, Back, Arms, and Legs.—C. C——, aged two, was admitted into St. Thomas's Hospital, under the care of Dr. Ord, on Oct. 4th, and died on Nov. 7th, 1881. The mother was attending Brompton Hospital at the time, and she had lost one of her three children from consumption. The patient was healthy until three months ago, when he began to have diarrhœa and to lose flesh, but had no vomiting. A week before he came in he had two convulsive fits. He had had pain in the head, and had been very fretful and drowsy. On admission, the child lay in a dull and listless condition, taking but little notice of anything, and only crying when disturbed. The head was drawn strongly backwards, and kept stiffly in that position. The back was likewise rigid. The arms were flexed, and the legs and feet extended, all being quite rigid. Patellar reflex was very brisk. There was no loss of sensation; deglutition appeared to be imperfectly performed. The pupils were dilated, but equal; and Mr. Nettleship pronounced the fundus of both eyes to be natural. Pulse 120. Loud rhonchi were heard over both lungs. The urine was free from albumen. During the rest of his life he became more and more drowsy, and had varying degrees of hyperæsthesia, but never loss of sensation. Rigidity of neck, trunk, and limbs continued without intermission, though it varied considerably in degree. Slight left internal strabismus and partial paralysis of the right facial nerve came on; and deglutition was more and more difficult, the food running out at the corners of the mouth. The fundus of the eyes was repeatedly examined, even as late as Nov. 6th, but no changes were found. The temperature, with very rare exceptions, was normal. On post-mortem examination I found the cerebro-spinal fluid much increased, and the lateral ventricles moderately distended with serum. There was slight basal meningitis, but the hemispheres were free from tubercular disease. In the cerebellum and pons were large greenish tubercular masses of rather irregular outline, that in the latter being in the position marked in the figure. It occupied almost the entire extent of that division of the brain (Fig. 10), having only a thin sheet of white matter around it. Longitudinally, it extended the whole length of the pons, but seemed to stop short of the medulla oblongata. Unfortunately, no microscopic examination of the spinal cord was made. The lungs were thickly studded with miliary tubercles, but the other organs appeared to be healthy. The masses in the cerebellum were all situated superficially in the cortex, and did not extend deeply into the substance of the organ.

FIG. 10.

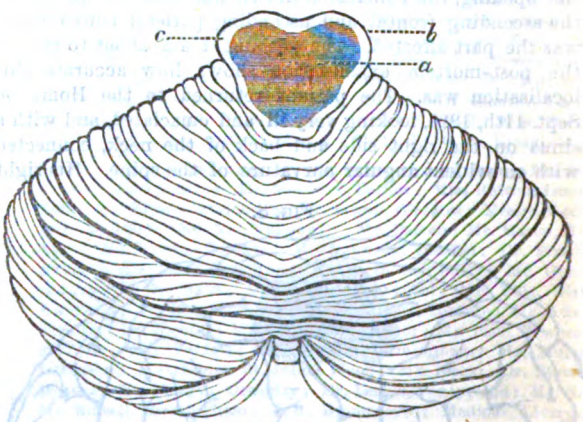

Diagram showing the position of a tubercular mass (*a*) as seen in a vertical section through the pons (*b*). The rim (*c*) represents the unaffected nerve substance.

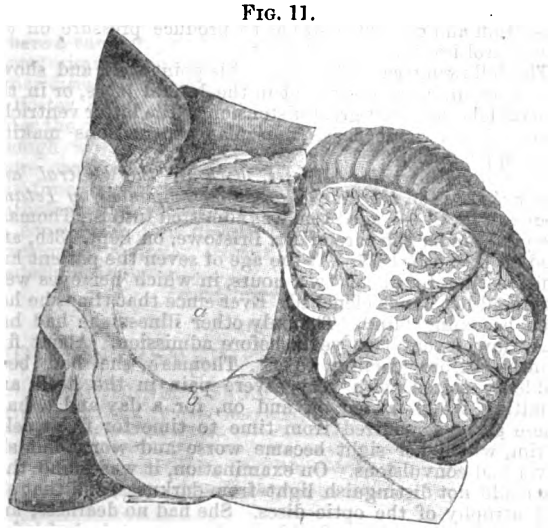

In this instance, again, the muscular rigidity must be referred to pressure exerted by the tumour upon the fibres of the pyramidal tracts in the pons; for tumours situated in the superficial parts of the cerebellar cortex are of pretty frequent occurrence, and are not found to give rise to any such symptoms. I shall presently relate a case in proof of this assertion.

Case in which a Tubercular Mass occupied the Aqueduct of Sylvius, and produced Tremors, Paralysis, and Spasmodic Contraction of Muscles.—E.B.——, aged seven, was admitted

Digitized by Google

into St. Thomas's Hospital, under the care of Dr. Bristowe, on August 2nd, 1882, and died on November 30th in the same year. His family history was unimportant, and the child himself had never suffered from fits, or from any serious illness, except from a blow on the head, which he received at the age of four, and which laid him up for a month. From this he perfectly recovered, and it was not until the end of May, 1882, that his present illness began. Having gone to bed quite well one night, he awoke next morning, throwing himself about, and he was found to have lost power in all his limbs, but most markedly in the right arm and leg, and he was unable to walk properly. He was said not to have vomited or lost consciousness. His speech was affected from the beginning, and his eyes about one week after the commencement of his illness. He was becoming weaker and thinner every day, and the tremors in his limbs, which were noticed at first, were becoming steadily worse. His bowels were confined, and he had lost control over his bladder; he was very drowsy, but his memory was good. He had all along been free from headache, vomiting, and convulsions. On admission the child was found to be rather thin and drowsy. He lay apathetically in bed, but could be easily roused if spoken to. He had weakness in the arms and legs, and when he walked his legs seemed to drag. The most striking peculiarity in his condition was, however, the tremor with which all his movements were accompanied. The head, neck, jaws, trunk, arms, and legs were all similarly

FIG. 11.

Drawing of a large tubercular mass (*a*) occupying the aqueduct of Sylvius, and by its pressure producing a cup-like depression in the pons (*b*). The section is vertical and longitudinal.

affected. When he used his hands and arms the tremors in them were marked, of rather short excursion, sometimes in the direction of movement, and sometimes at right angles to it. The jaws trembled when he used them, and speech was slow and drawling. The tongue was protruded straight, and when he smiled the mouth was drawn somewhat to the right; hearing was normal. All the muscles of the eyeballs were more or less weakened. There was ptosis on both sides, and the internal rectus of the right eye was markedly affected. The superior and inferior recti on right were likewise weak, as were the muscles of the left eye, though not so weak as those on the opposite side. Both pupils acted well to light and to accommodation, the right being a little larger than the left; no anæsthesia was present. The patellar and plantar reflexes were normal, and there was no ankle-clonus. The temperature was natural, and all the organs, except the brain, appeared to be healthy. During the rest of his life the tremors gradually increased, paralysis became more marked, and attacks of spasmodic contraction of the muscles of the limbs and trunk occurred from time to time. On some occasions the legs were noticed to remain for a while rigidly extended. The patellar and plantar reflexes became exaggerated. The patient grew more and more drowsy, and passed his evacuations in bed. The temperature presented only occasional slight elevations until November 26th, four days before death, when it rose to 101·2°; and it subsequently reached 103·8° on the 29th, the day before death. Throughout the patient's illness there was a singular absence of headache, vomiting, and optic neuritis. Though frequently examined, the fundus of the eye presented no abnormal appearances until November 26th, when there was thought to be neuritis. After death, Dr. Edmunds found distinct microscopic evidences of this condition. Another curious point was that the tremors were now and then either greatly diminished or absent for a day or two, and then returned with all their former intensity. At the necropsy the body was much emaciated, and rigor mortis was present only in the lower extremities. The spleen and lungs contained a few tubercles, and those in the spleen were caseous. All the other organs were healthy, with the exception of the brain. Its surface was sticky, and the veins were gorged with blood. At the base, in the interpeduncular space, the membranes were opaque and there was fluid in the optic sheath. Miliary tubercles were present in the Sylvian fissures, and the ventricles were moderately distended. There was a large caseous mass in the region of the corpora quadrigemina, which was round in shape and as large as a medium-sized marble, and which is well displayed in the preparation before you (Fig. 11). It lay as if wedged in the aqueduct of Sylvius, which was enormously distended. On the upper surface of the tumour were the thinned and flattened corpora quadrigemina, while its lower rounded margin rested upon the upper surface of the pons and crura cerebri. Here it occupied a cup-like cavity, which its downward pressure had produced. No other important structures were injured by the tumour.

In this case the usual phenomena of pressure upon the fibres of the pyramidal tract are again well represented. Paralysis and tremors occurred first, then attacks of rigidity. Had the child lived longer and the growth of the tubercular mass progressed, the pressure exerted by it upon the pons and crus cerebri would, no doubt, have produced the final stage of persistent rigidity. The recent tubercular meningitis cannot be said to have produced the tetanic seizures, as the latter occurred months before the patient's death. This case and the next which I shall relate have already been published by Dr. Bristowe in *Brain*, vol. vi., p. 167.

Case of Tubercular Mass occupying the Left Lobe of the Cerebellum, and pressing upon and producing Softening of the Pons and Medulla; Persistent Rigidity of Limbs.—A. G. J——, aged four, was admitted into St. Thomas's Hospital, under the care of Dr. Bristowe, on Dec. 30th, 1878, and died on August 6th, 1879. He had been a healthy child until three months previously, when he was ill with measles and whooping-cough. He began to have fits, which occurred about once a day at first, and then twice a day. He had also been suffering from severe pain in his head, occasional vomiting, and for about two months his mother had noticed that he squinted. The father was said to be asthmatic, and the mother had a weak chest, but their two other children were healthy. On admission the patient seemed to be a sensible child, but quite blind. The pupils were widely and equally dilated, and contracted slightly to light. When lying in bed he could move his arms and legs, but the former were tremulous and ataxic. When placed upon the ground, the patient laughed hysterically, but could not stand, though he could move his legs forwards when supported. The limbs appeared to be equally affected on the two sides. The mouth dropped slightly on the right side, and the tongue was protruded to the right. The pulse was 140 and regular; respiration was easy. The patient passed all his evacuations in bed. There was well-marked optic neuritis in both eyes, the outline of the discs being irregular and blurred, the veins large, the arteries small, and the whole presenting a streaky appearance. Between the time of admission and his death the patient had many fits, in which he was unconscious—the legs remaining rigidly extended, and the arms being flexed and then extended several times in succession. A certain amount of left facial paralysis developed, so that the patient could not close the eye of that side, and the left external rectus was partially paralysed. His arms became more tremulous, the right being more affected than the left; his speech was very drawling. He remained for long fairly intelligent, had no deafness, and was not much troubled with headache or vomiting. From February onwards the arms and legs became persistently rigid, although the degree of rigidity varied. Finally, the child became emaciated to the last degree, and lay perfectly still, taking food well when it was offered him, but showing very few signs of life. He died on

Digitized by Google

August 6th. At the post-mortem examination there was little evidence of important pathological changes in any of the viscera except the brain. The head was very large, all the sutures were separated, and the bones were movable. There was no subarachnoid fluid, but the ventricles were greatly distended, and the substance of the hemispheres reduced to a thin, soft sheet of nerve substance. The left lobe of the cerebellum was entirely occupied by a firm tumour, of the size of a Tangerine orange, yellowish-green in colour, semi-transparent, and consisting of closely placed, concentric layers. The relics of cerebellar tissue remaining on its surface were soft, as was the neighbouring part of the posterior cerebral lobe. The tumour was adherent to the tentorium cerebelli, and the pons and medulla were pressed upon by it, and somewhat softened. The right lobe of the cerebellum was healthy. Another small tubercular mass was found in the grey matter on the orbital surface of the right frontal lobe. In this case, again, persistent rigidity was the result of pressure which the tumour exercised on the medulla oblongata and the pyramidal tracts which run in it. For it will be shown presently that without such pressure tumours of the cerebellum do not produce such phenomena, and that distension of the ventricles with fluid is not sufficient to explain them.

These four cases appear to me to be of great interest as representing diseases affecting a certain portion of the brain, and capable of being localised during life. The region referred to extends from the basal ganglia to the medulla oblongata, commencing at that spot where the pyramidal tracts begin to converge as they pass between the central ganglia, and occupying further on the pons and medulla oblodgata, where the pyramidal tracts lie in close contact. If the motor tracts be affected simultaneously, or quickly one after the other, in the way about to be mentioned, the disease is likely to be situated between the basal ganglia above and the medulla below, and is in all probability a tumour. The earliest symptoms referable to the pyramidal tract are tremors; then come paralysis and rigid contraction, which is finally permanent; and besides these there may occur from time to time attacks of tetanic spasms, affecting most of the muscles of the body. The phenomena of chronic spasm are due to gradual pressure on the motor tracts, proceeding from the central convolutions of the brain; and the fact that both sides of the body are attacked indicates that the disease is situated at a part where the pyramidal tracts are in close proximity to each other. If the case be seen early, probably all these symptoms, tremors, paralysis, and rigid contraction, will occur before the end; but if the patient do not come under observation until late, only some of them may be observed. Thus, in the case where the optic thalami were gradually invaded, and in the case of cerebellar tumour pressing from above on the medulla, all occurred; whereas, in the case of the large tubercular mass almost completely occupying the pons, only the later stage of persistent rigidity was seen. In determining the exact seat of the tumour, whether in the optic thalami, corpora striata, pons, or cerebellum, we must consider the other symptoms referable to the special nerves involved, which arise at different levels along the base of the brain, and also whether there are, or have been, symptoms which suggest cerebellar disease. Moreover, optic neuritis is very constant, and early in its appearance in cerebellar disease, and often late when the tumour is higher up. I would not have it understood that all tumours in these positions give rise to the phenomena described, for soft succulent ones often do not; but if the symptoms I have pictured be present, the disease is probably a hard slowly growing tumour in the area mentioned. In all the cases just related the tumour was a large tubercular mass; and the early stage of such tumours is shown in a specimen on the table, which was taken from the body of a baby who presented no obvious symptoms of cerebral disease. A caseous nodule can be seen (Fig. 12) occupying the lower third of the external segment of the lenticular nucleus. In a drawing of a microscopic section of this mass a large vessel is seen, and close by the vessel [illegible] of well-stained tubercule bacilli (Fig. 13). [illegible] as this series of cases is from the point [illegible] considered, they are still more so in their bearing upon the question of the functions of the cerebellum and its relation to muscular spasm. In THE LANCET of 1880, vol. i., p. 122, Dr. Hughlings Jackson has written "On Tumours of the Cerebellum," and speaks of "cerebellar rigidity." "I suppose," says he, "the cerebellar rigidity to be owing to unantagonised cerebral influx (rigidity in hemiplegia being owing to unantagonised cerebellar influx), and the tetanus-like seizures to be owing to cerebellar discharges analogous to those cerebral discharges which produce unilaterally beginning (epileptiform) convulsions. But there is the obvious objection that the two symptoms, with the cerebellar disease, may be owing to interference with the corpora quadrigemina (electrical excitation of which produces tetanus-like states), or to interference with the medulla oblongata." Further on in the same volume of THE LANCET, p. 522, Stephen Mackenzie has a paper on the same subject, in which he expresses the opinion that "the reeling gait and tonic spasms are both expressions of disorder of the locomotory apparatus, of which the cerebellum is the governing centre." In comparing the tetanus-like seizures with tetanus, he goes so far as to say, "the range of the two is so much alike as to afford the strongest reasons for the belief that tetanus is an affection of the cerebellum." Now, if the same rigid contractions and the same tetanic seizures occur in disease of other parts at the base of the brain, they cannot be held to be characteristic of cerebellar disease. Hughlings Jackson says: "This universal rigidity, as a condition arising from cerebellar disease, I have seen only when the tumour has been in the middle lobe," and again: "In the case of extensive rigidity and tetanus-like seizures, the tumour has been of the middle lobe, and has been large." These remarks really furnish a clue to the matter. I would put the case thus: a tumour of the cerebellum does not produce contractures and tetanic seizures, unless it be in such a position and of such a size as to produce pressure on the pons Varolii or medulla oblongata.

The following case illustrates this point well, and shows that tumours may be present in the lateral lobes, or in the central lobe, and that great distension of the latter ventricles may exist without these muscular contractions making their appearance.

Case of Tubercular Masses, both in the Central and Lateral Lobes of the Cerebellum, unaccompanied by Tetanic Spasms.—E. C——, aged ten, was admitted into St. Thomas's Hospital, under the care of Dr. Bristowe, on Sept. 13th, and died on Dec. 5th, 1877. At the age of seven the patient had a fit, lasting for about two hours, in which her eyes were fixed and her hands clenched. Ever since that time she had been becoming blind. The only other illness she had had was "low fever," two years before admission. About five months before coming to St. Thomas's she had been suddenly seized with very severe pain in the head and vomiting, which lasted, off and on, for a day and a half. These attacks recurred from time to time for five weeks, during which her sight became worse and worse, but she never had convulsions. On examination, it was found that she could not distinguish light from darkness, and that she had atrophy of the optic discs. She had no deafness, and was very intelligent, and able to give a great deal of information about her illness. Her head was somewhat hydrocephalic in shape, and the forehead prominent. She kept it fixed, and said it hurt her to let it drop backwards. When seated the legs appeared to be quite strong, and it was impossible to detect any weakness in them when one tried to flex or extend them against her will. When held by the hands she could walk pretty well, but when she was left to stand alone she quickly lost her balance. The same occurred when she tried to walk, and she seemed to have considerable incoördination of the legs. There was a tendency to fall to the right side, though she was said previously to have usually fallen to the left. When standing up and made to lean a little backwards she did not fall, but ran backwards. During the rest of her life she had frequent attacks of severe pain in the head, accompanied by vomiting and a feeling of great giddiness. Her temperature remained normal, and she had no tetanic spasms or contractures. She was found dead in bed on the morning of December 5th. At the necropsy, there was no evidence of meningitis, but the ventricles of the brain were distended with clear fluid, twelve ounces being removed and measured. The convolutions were flattened, and the whole extent of them collapsed when the ventricles were emptied. The optic nerves were markedly atrophied. The lateral lobes of the cerebellum were both very soft and swollen, and the left was adherent to the dura mater. There were several tumours, both in the central and in the left lobe, which appeared to be tubercular masses with the centres broken down. Their size varied from that of a pea to that of a medium-sized marble; their circumference consisted of a pale, rosy-grey, semi-translucent,

Digitized by Google

hard tissue, and their centres of a puriform fluid. The other organs were healthy.

In the class of cases which I have been discussing, tremors and paralysis are probably due to slight interference with the functions of the fibres of the pyramidal tracts, persistent rigidity to still greater interference, while the attacks of tetanic spasms may resemble the convulsions which are observed in connexion with cortical tumours of the brain. In the case of cerebral tumours, the pressure is exerted upon the cortical grey matter; in the cerebellar cases, upon the grey matter in the floor of the fourth ventricle, and not upon that of the cerebellum itself, for I have seen cases in which the central lobe of the cerebellum has been completely destroyed by tumours, but in which no pressure was exerted upon the medulla oblongata, and no rigidity was observed during life. It is interesting to note, in relation to this question, that Nothnagel has found that irritation of these parts is particularly liable to produce convulsions; so much so that he has supposed a special convulsive centre (Krampfcantrum) to exist in the pons, which is readily brought into action, either directly or reflexly, by stimulation of a spot in the fourth ventricle. I have said that the tetanic spasms "may" be due to pressure on the grey matter of the floor of the fourth ventricle, because they are capable of another explanation; they may, in fact, be the result of varying pressure upon the pyramidal tracts. In the next lecture I shall relate a case where a tumour, pressing upon the cord from without, produced similar spasmodic attacks; and they are also seen in other diseases affecting the lateral columns of the cord.

Foster, in his work on Physiology, says: "We must consider the cerebellum as an important organ of coördination, though we are unable at present to define its functions more exactly." This probably represents our knowledge of the functions of the cerebellum, and it is in keeping with pathological experience; and I do not think we are justified in considering that disease of it produces spasmodic contraction of muscles, except indirectly, by pressure upon underlying structures.

ON SOME

MODERN REMEDIES IN HEART DISEASE.

BY A. ERNEST SANSOM, M.D. LOND., F.R.C.P.,

PHYSICIAN TO THE LONDON HOSPITAL, CONSULTING PHYSICIAN TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN, LECTURER ON MEDICAL JURISPRUDENCE AND PUBLIC HEALTH AT THE LONDON HOSPITAL MEDICAL COLLEGE, ETC.

(*Continued from p. 536.*)

I NOW turn to the evidence, in cases under my own care, of mitral regurgitation in which caffeine citrate was administered. It is to be borne in mind that all these were cases of great gravity, in which the resources of ordinary treatment had been for the most part exhausted.

1. *Effects on the excretion of urine.*—In the following table insignificant variations have not been recorded. The signs < and > indicate a gradual daily increase to or a gradual daily decrease from the amounts stated.

TABLE I.—*Showing the daily amounts of Urine, in ounces, in cases of Mitral Regurgitation, treated by Caffeine Citrate.*

Case.	Before caffeine.	During administration of caffeine.	After caffeine.
1	12	36, 40, 114	180, 172, 114, 68, 57
2	—	24, 42, 47, 52	40, 32, 28
3	—	32, 64, 112, 117	
4	10, varying to 20	20, 30, 36	48, 20, 32>15
4a*	—	16<27, 65>36, 10	—
5	15, 20, 17	25, 20, 10, 25	—
6	50, 18, 15	30, 34, 20, 25>15<26	18, 14, 20>10<15, 20
6a*	—	20, 18, 15	—
7	17	35>12<30, 25	10
8	25, varying to 36>24	30, 29>11>6	—

* Readministration.

It must be accorded that the evidence of these cases proves the citrate of caffeine to be, in cases of mitral regurgitation, a powerful diuretic. It is shown that the amount of urine passed during a considerable portion of the period when the drug was administered was generally in excess of the diurnal amount passed previously. In some cases the effect is very striking; for instance, in Cases 1 and 3, in which the daily amount ran up in the one case from 12 oz. to 114 oz., and in the other from 32 oz. to 117 oz. In both these cases ten-minim doses of tincture of digitalis were administered with the caffeine citrate, in the first case in three-grain, in the second in five-grain, doses three times a day. It is also, in my opinion, indicated that the influence of the drug as a diuretic may be prolonged beyond the time of its actual administration. Cases 1 and 4 tend to show this, and to indicate that the dictum that caffeine is not cumulative in action must be reconsidered. The cases, however, abundantly prove another proposition—that the diuresis produced by the drug is not invariably salutary, and that the free outflow of urine is not an index of rehabilitation of the general vital powers. In Case 1 the effects were remarkably favourable; there existed extreme ascites and œdema in a woman of fifty-three, the left ventricle being much dilated and hypertrophied; then occurred amelioration and disappearance of all the symptoms, and the patient left the hospital feeling well. There can be no doubt that here the effects were rapidly beneficial. A like result was manifested in Case 2, in which there was evidence of aortic obstruction as well as mitral regurgitation. This case was subsequently treated by convallaria, but the maximum of diuresis was markedly during the *caffeine* period. This patient recovered from all her very distressing symptoms, and went out feeling well. In Case 3, however, one of extreme severity, in which pericarditis, signs of embolism, and renal complication occurred, the patient died at the very time that the amount of urine passed in the day had reached the high figure of 117 oz. May prolonged administration tend to diminish or exhaust the diuretic effect? In Case 4 the second administration was followed by a steady and gradual increase to a maximum daily excretion of 65 oz., but the administration being continued the outflow fell to 36 oz., and then to 10 oz. In this case aortic disease coexisted; the patient died. In Case 6 there was a slight diminution under the protracted influence, but here there were very severe complications—viz., empyema and renal disease; this patient died, death being, one might say, inevitable. In Case 8, in which death occurred, there was a steady diminution of the urinary outflow during the administration; but here, in a woman of sixty-four, there existed great ascites and œdema, with advanced granular disease of the kidneys. Considering that in all these cases the great severity of the complications might in themselves constitute a constant and progressive cause of enfeeblement of cardiac muscle, we should not conclude that the urinary inadequacy was due to any action of the drug itself; it might with so much probability be due to a gradual extinction of the powers.

2. *Effects on pulse and respiration.*—The following table indicates the results:—

TABLE II.—*Showing rates of Pulse and Respiration in cases of Mitral Regurgitation treated by Caffeine Citrate.*

Case.	Before caffeine.	During administration of caffeine.	After caffeine.
1	Pulse 117	100, 94, 96	95
	Respiration	30>20	—
2	Pulse	92>56	74>57, 70, 72
	Respiration	30>23	21
3	Pulse	120, 144, 132	—
	Respiration	32, 36, 30, 28	—
4	Pulse 72, var. to 84	96, 112	—
7	Pulse 78 ,, 90	96	120
	Resp. 48 ,, 36	36	54
8	Pulse 100 ,, 114	*	—

* Became quick, small, and weak. Insomnia. Became worse, and died.

It will be noted that the data in two of the cases have been omitted; this has been because they were variable or doubtful. There is evidence, however, as regards some of the cases, that the rates both of pulse and respiration were reduced under treatment by caffeine. In Cases 1 and 2 the influence was very decided. The sphygmogram taken shortly after admission (Fig. 1) shows with insufficient volume a great irregularity with interpolated systoles. After five days of treatment the second sphygmogram was taken, and it is seen that the pulse has become nearly regular

Digitized by Google

(Fig. 2). In Case 2 the combined effect of convallaria and caffeine is well shown. The pulse, which at commencement

FIG. 1.

Sphygmogram in a case of mitral regurgitation, with œdema and ascites.

of treatment was 92, had now, after six days of treatment, not only become reduced in frequency to 52, but had

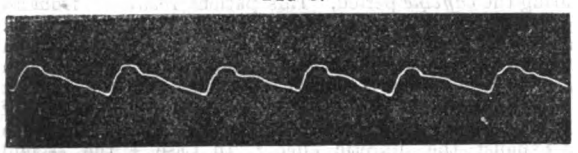

FIG. 2.

Sphygmogram in the same case after five days' treatment with caffeine citrate.

acquired marked evidence of tension, as shown by the sphygmogram (Fig. 3). In the other cases, complicated as

FIG 3.

Sphygmogram in a case of mitral regurgitation treated by caffeine and convallaria in combination.

I have stated them to be, there was no such favourable reaction, though in Case 7 it is shown that on the omission of the caffeine the rate of pulse and respiration rose in very considerable degree.

3. *Effects on the temperature of the body.*—In Case 1 the temperature was nearly normal throughout. In only one case (3) was there a rise of temperature under caffeine; then it was from subnormal to 100° F. In the other cases the reduction was from a subfebrile temperature to normal or subnormal. In Case 7 the temperature previously to the administration varied between 99° and 102°, and during the administration between 98° and 100°. It may therefore be concluded that in such cases as we have been considering, caffeine tends to depress the temperature. I think we are justified in concluding that caffeine, in the treatment of cases of mitral regurgitation in which failure of compensation has occurred, is a valuable agent; that it is a powerful diuretic, and is therefore very valuable in cases manifesting dropsy; that it tends to increase the force of the heart, to calm the respiration, and reduce the temperature; but that it fails in some cases to be of benefit, even though it may manifest its diuretic effect. Like other heart-tonics, it fails especially in pericarditis, where probably the direct enfeebling agency of the disease upon the myocardium is a cause which operates against it.

I now turn to another remedy of comparatively modern introduction—

Convallaria majalis.—This plant, the well-known lily of the valley, has long been used for the treatment of dropsy in Russia, in the form of an infusion of the flowers and leaves. M. Germain Sée of Paris, made a careful study of it as a therapeutic agent, and I called attention to its use in my Lettsomian lectures for 1883. In those lectures I said that I looked hopefully to the drug in the treatment of failure of the right heart in cases of mitral stenosis. Its therapeutic efficiency resides in the principle convallamarin, a glucoside, which may be administered in doses of from half a grain to two grains daily: on account of its cumulative tendency only one dose of convallamarin should be administered each four hours. The following are its preparations and administration:—1. Extractum convallariæ is an aqueous extract of the flowers and stems (two parts) and roots and leaves (one part), the dose being from two to eight grains. 2. Extractum convallariæ fluidum, dose from two to ten minims. 3. Tinctura convallariæ, dose five to thirty minims. Convallaria is classed with digitalis as a stimulant of the muscular fibre of the heart, and is said to act more slowly and more persistently than the latter. Within the last two years convallaria has been extensively used in the treatment of various forms of cardiac disease. The experience of various observers in regard to it is very contradictory; so great is the discrepancy that it has been suggested that the activity of the plant varies with the locality in which it is grown. If this be a difficulty, of course it can be obviated by the employment of the active principle—convallamarin. According to many observers—e.g., Germain Sée, Bochefontaine, A. H. Smith, Labbée, Frederick Roberts, Ott, and others—very valuable results are produced by the drug in cardiac diseases. On the other hand, Leubuscher has declared that it has proved in his hands worse than useless as a remedy. Heller has also given an unfavourable report.[1] Professor Jaccoud says concerning it:—"It is a very untrustworthy medicament, and many cases are quite refractory in regard to it. You must not count upon it, and in cases of urgency you would be wrong to fill up by its administration the intervals of a digitalis course; these you should rather confide to caffeine. If this latter is not well borne, we have no other resource than convallaria; but, I repeat, do not count too much upon it."[2] In estimating the value of such a drug, it is most important, in my opinion, to group the cases. Those on which the conclusions of the various observers have been based were very different forms of heart disease and heart disturbance. I now proceed in the same manner, as in the case of caffeine, to inquire concerning the influence of convallaria in mitral regurgitation. In the cases compressed in the following table convallaria was administered in doses of five grains of the extract or twenty minims of the tincture three times in the day.

TABLE III.—*Showing the daily amounts of Urine, in ounces in cases of Mitral Regurgitation, treated by Convallaria.*

Case.	Before convallaria.	During administration of convallaria.	After convallaria.
1	20	21, 25, 30 > 16 < 30 > 20	30 > 20 < 30, 26
2	20, 30	35, 17, 22, 20, 27, 22	35, 22, 27, 30, 25
3	—	45, 48, 40 < 60, 69, 60 > 52 < 60	—
4	20, 40	45, 64 > 10	—
5	13 < 35 > 10 < 80 > 35	20, 28 > 15	—
6	—	17	35, 30 > 10

If we took the evidence of these cases as indicating the action of convallaria in cardiac disease generally, we should conclude that it is a feeble diuretic. I must ask that judgment be withheld until after consideration of its action in mitral stenosis. It is seen that in four of the cases a slight diuretic action was soon manifest; the maximum diuresis was attained in one, two, four, and eight days; except in Case 3, there was on continuation of administration a tendency to a diminished excretion. In Case 6 the drug was only given for two days; and then, as urine was very scanty, digitalis and caffeine were substituted, with the result of a very decided but temporary increase. So far as these cases show, the influence of convallaria as a diuretic in cases of mitral regurgitation is far inferior to that of caffeine.

The effects of convallaria on pulse and respiration in cases of mitral regurgitation are indicated in the following table

TABLE IV.—*Showing rates of Pulse and Respiration in cases of Mitral Regurgitation treated by Convallaria Majalis.*

Case.	Before convallaria.	During convallaria.	After convallaria.
1	Pulse	120 > 104 < 120	120 > 108
2	Pulse 114	112 > 108	104 < 124
	Respiration 36	34 > 24	34 > 20
3	Pulse	72	—
	Respiration	20	—
5	Pulse 134, 140 > 104 > 76	70	—
	Respiration 28 < 36 > 24	No imprt. of dyspnœa	—
6	Pulse	Varying betw. 78 & 90	Var. betw. 96 & 120
	Respiration	,, ,, 36 & 48	Increased to 54
7	Pulse	96, 120 > 108	—
	Respiration	22 < 40 > 20	Much imprvt. foll.
8	Pulse 120, 98, 88	108 > 84, 90	84 < 108 > 72
	Respiration 27	36 > 30	28, 24, 20

It is seen that, as a general rule, the rates of pulse and breathing are reduced under the influence of convallaria.

[1] See Dr. Mitchell Bruce's Summary in Cassell's Year-book of Treatment for 1884, p. 5, *et seq.* [2] Semaine Médicale, Jan. 13th, 1886, p. 10.

Digitized by Google

That the force of the heart and tension of the pulse coincidently with a good regularity of rhythm *may* be brought about I have graphic evidence to prove. Case 5, however, shows that, even though the pulse-rate be very greatly reduced, there may be no relief from the embarrassment of respiration. This case was one in which there was much cardiac dilatation, and it was complicated by embolism of the right axillary artery. The pulse-trace manifested much irregularity and pronounced dicrotism. Case 7 was complicated with aortic obstruction and regurgitation. Three grains (a smaller dose than that administered in all the other cases) of the extract of convallaria were given three times a day; here, though there was during treatment a temporary increase of the rates of both pulse and respiration, the rate of the latter became notably reduced. This patient was discharged after having manifested much improvement.

Effects on temperature.—In only two cases was there a rise of temperature under the treatment by convallaria; in neither did it rise above 102°, and in one it fell to 99° at the end of the period of treatment. Generally there was after commencement of treatment a slight fall of temperature, and this sometimes occurred suddenly. The lower temperature persisted for some days after the cessation of convallaria, and then as a rule the temperature rose again or became irregular.

General effects.—Cases 1, 4, 5, and 6 manifested no signs which seemed to me to indicate that the drug exerted any marked influence for good, or that it was in any way superior to digitalis. Two of these cases died, one of them being complicated with pericarditis, pleuritis, and pulmonary infarction; the others tided over their difficulties, and were ultimately discharged from hospital. In Case 2, where aortic disease was combined with mitral, much general improvement was manifested two days after the termination of the treatment by convallaria; one week afterwards there was relapse with extreme dyspnœa and death. Case 3, which was also complicated with aortic disease, manifested great improvement; Case 7, with a like complication, also; and in Case 8, which was of the hopeless form of post-partum endocarditis, manifested improvement during the period of convallaria treatment, the temperature then being notably subdued, to manifest irregular rise and fall subsequently.

My general conclusion is that in convallaria we have a drug which may be occasionally used with advantage in cases of mitral regurgitation; that it should be continued for no longer than weekly periods without interruption; that in cases manifesting dropsy it should be accompanied with caffeine; but that for general and systematic administration in mitral regurgitation it will not (except at intervals) usefully supplant digitalis.

(To be concluded.)

THE

ANTISEPTIC TREATMENT OF WOUNDS.

BY SURGEON-MAJOR W. GRAY,

SENIOR SURGEON, JAMSETJEE JEJEEBHOY HOSPITAL, AND PROFESSOR OF SURGERY, GRANT MEDICAL COLLEGE, BOMBAY.

THE following account of my experiences in the pursuit of antiseptic surgery in the wards of the Jamsetjee Jejeebhoy Hospital will, I trust, prove of interest to those who may be engaged in similar investigations. To render it of real value the failures as well as the successes will be described; there is as much to be learned from the one as from the other. The experiments I am about to record were instituted with the object of devising an antiseptic method of dressing wounds which should be not only effective but cheap and easily and quickly applied. The various modifications of treatment were at first employed with amputation and other operation wounds, and latterly with wounds of all kinds. It is only with amputations, however, that I shall deal at any length for the present. The series of cases consists of forty-two amputations successively treated from Nov. 1882 to Dec. 1884, and of these I shall give a short account, either singly or in groups, according to the mode of treatment adopted, and its results. To save time, it will be understood that each patient was in the best condition possible under the circumstances, and that extreme cleanliness of the part to be operated on, of the instruments, assistants, and materials of all sorts used, was insisted upon, and ensured by personal supervision. In fact, to be certain that everything was perfectly clean I always attended to this part of the work myself. The dressings, ligatures, and lotions I kept in my own custody. Mistrusting, as a rule, the purity or quality of the hospital supplies, I usually purchased the first two, the best I could procure, and made the third myself. In this way I possessed an intimate personal knowledge of the materials employed, and in case of failure was in a better position to lay my finger on the weak point of the procedure than if I had to trust to the knowledge or conscientiousness of others. I may also mention that carbolised catgut ligatures, rubber drainage-tubes, and silver sutures were invariably used. I now proceed to detail the cases.

CASE 1.—Female, aged eighteen. Syme's amputation of right foot for sarcoma involving the toes and anterior part of foot. Operation performed on Nov. 3rd, 1882. The stump was washed with a 5 per cent. solution of boro-glyceride, then covered with strips of lint wrung out of the same solution; over this a thick layer of cotton was placed, next a layer of oakum, and the whole was enveloped in a sheet of oiled paper fixed on with adhesive plaster. In this case the temperature remained normal throughout. The dressings were removed for the first time on the twelfth day after operation, when firm union was found to have taken place. The sutures and drainage-tube were withdrawn, a little light dressing applied, and the patient was discharged well on Nov. 24th. On inspection of the first dressing at the time of removal it was found to be perfectly sweet; not a drop of pus had formed, but the cotton and oakum were more or less moist, obviously from retention of the cutaneous exhalation by the waterproof.

CASE 2.—Male, aged thirty. Flap amputation at the middle of the right leg for disease of the ankle-joint. Operation, Jan. 16th, 1883. Dressing as in the preceding case. Temperature remained normal. The stump was opened for the first time on the ninth day. Union firm. After-treatment as before. Patient discharged cured on Feb. 12th.

CASE 3.—Male, aged twenty-five. Flap amputation of right thigh, at lower third, for knee-joint disease. Operation, Jan. 24th. Dressings as before. On the second day the temperature rose to 100·2°; and on the fifth day, it being evident that suppuration had occurred, the dressings were taken off and the stump treated as an open wound. Patient discharged well on April 5th. The failure here was doubtless due to a small portion of diseased tissue, part of a sinus wall having been left behind.

CASE 4.—Male, aged thirty-five. Flap amputation of right thigh, about the middle, for disease of the knee-joint. Operation, Feb. 19th. Parts much diseased. Dressings as before. Temperature rose, as in Case 3, and, suppuration setting in, the dressings were removed. The patient, however, being much reduced and enfeebled from long-continued joint disease, died of exhaustion on March 5th.

CASE 5.—Male, aged sixty. Amputation through right knee-joint for machinery smash of the leg. Operation, March 31st. Dressings as already described, except that dry lint was substituted for cotton, and gutta-percha tissue used instead of oiled paper. Temperature 102° next day, and, continuing at and above 100°, the dressings were taken off on the fourth day. A considerable quantity of pus had already formed. The stump was treated as an open wound, and the patient left hospital well on July 3rd.

CASE 6.—Male, aged thirteen. Amputation at middle of left forearm for machinery smash. Operation, April 1st. Dressings as in the preceding case. Temperature rising, the stump was exposed on the seventh day, when putrefaction to a slight degree was seen to have occurred. The wound was now treated by the open method, and the patient was discharged cured on May 6th.

In the last two cases I am probably nearest the truth in attributing failure to imperfect disinfection of the wound and surrounding parts before applying the dressing. I have observed a greater proportion of failures in accident cases where the flaps include more or less of the injured, though sometimes apparently sound, tissues, especially where there is loose skin or dragged tendons. This injured tissue is often dirty, or it may fail to recover vitality.

CASE 7.—Female, aged twenty-five. Amputation at lower third of right leg for disease of the ankle-joint. Operation,

Digitized by Google

April 15th. Boro-glyceride dressing. Temperature remaining normal, the stump was not exposed till the ninth day, when firm union was found. Patient discharged well on May 28th.

CASE 8.—Male, aged thirty-six. Amputation just below the left knee for extensive syphilitic necrosis of the tibia. Operation, May 13th. Iodine water was used in this case instead of boro-glyceride, the latter being discarded as too expensive. The covering of oakum was made thicker, and was kept on with a bandage firmly applied. By way of making the dressing air-tight the upper edge of the bandage was secured with a broad strip of elastic. Temperature remaining normal, the dressings were left untouched till the next day, and on removal the stump was seen to be healed. The patient, however, for other reasons, was not discharged from hospital till Aug. 13th.

CASE 9.—Male, aged twenty-five. Amputation at middle of right leg for smash of its lower part. Operation, May 14th.

CASE 10.—Male, aged twenty-five. Amputation through left wrist for machinery crush of the hand. Operation, May 14th.

CASE 11.—Male, aged fifty. Amputation through right knee for railway smash. Operation, May 17th.

CASE 12.—Male, aged thirty. Amputation at lower third of left leg for smash of the foot and ankle. Operation, May 17th.

The dressing in each of these four cases was iodine water, lint wrung out of the same solution, oakum, waterproof, and bandage. Cases 9, 11, and 12 were successful, uniting by first intention; but Case 10 was a failure, and the stump had to be treated from the fifth day as an open wound. The patients were discharged well on June 29th, June 13th, June 9th, and June 29th respectively. Case 11 was a drunkard, and a fat, flabby subject, yet he made the best recovery.

CASE 13.—Male, aged forty. Amputation at middle of left leg for disease of the ankle-joint. Operation, May 21st. Iodine water dressing as before. Death on ninth day from tetanus. The dressing, however, was so far perfectly successful; union had taken place, and there was no sign of suppuration.

CASE 14.—Male, aged nineteen. Amputation below right knee for advanced disease of the ankle-joint. Operation, July 3rd. Patient phthisical. Stump washed with 1 in 1000 solution of corrosive sublimate; it was then covered with two layers of lint wrung out of the solution; over this a thick pad of boric cotton, oakum, waterproof, bandage, and elastic. The result was excellent. Dressings removed on the ninth day, and stump found healed. Patient discharged well on July 23rd.

CASE 15.—Male, aged thirty. Amputation through right knee-joint for mycetoma. Operation, Aug. 16th. Dressings and results as in the foregoing case. Discharged cured on Sept. 7th.

CASE 16.—Male, aged twenty-five. Syme's amputation for spontaneous gangrene of the right foot of one month's duration. Operation, Aug. 19th. Dressings as before. Temperature rose to 101° on the second day and remained so. The stump was exposed three days later, when sloughing of the flap was seen to have taken place. This was undoubtedly due to deficient vitality of the part. A more favourable result would probably have occurred had amputation been allowed higher up. Patient discharged at his own request on Nov. 11th, the stump not even then being entirely healed.

CASE 17.—Male, aged twenty-five. Amputation at right shoulder-joint for railway crush of arm. Operation, Sept. 5th. In this case the old-fashioned open dressing (lint wrung out of carbolised oil) was used. The skin on the side of the chest and over the shoulder was badly bruised, had lost its vitality, and consequently sloughed. The patient, however, made a good though slow recovery, and was discharged well on Dec. 5th.

CASE 18.—Male, aged forty. Syme's amputation for railway crush of the left foot. Operation, Sept. 19th. Dressings as before. Temperature rising beyond 100°, the stump was opened up on the sixth day, when a large portion of the flap was found to have sloughed. Treated from this time as an open wound. Discharged well on Dec. 20th.

CASE 19.—Male, aged thirty. Amputation at the upper third of the right arm for machinery smash. Operation, Nov. 10th. Dressings as before. Removed on the eighth day. Firm union. Discharged cured on December 4th.

CASE 20.—Male, aged forty. Secondary amputation at the middle of the right thigh for tramcar crush. Operation, Nov. 22nd. The parts being more or less inflamed and infiltrated, open dressing was used. Patient died exhausted on Dec. 2nd.

CASE 21.—Female, aged fifty. Syme's amputation of the right foot for disease of the tarsus. Operation, Nov. 27th. Patient a feeble old woman. Dressing, corrosive sublimate solution and boric cotton. Temperature rising, the stump was exposed on the fourth day, when commencing suppuration was seen. Treated from this time by the open method. Patient discharged cured on Jan. 29th, 1884.

CASE 22.—Male, aged thirty. Syme's amputation for railway smash of left foot. Operation, Dec. 14th. Dressings as before. Temperature rising, they were removed on the third day, when a portion of the skin over the inner ankle, which had been separated by the injury from the structures beneath, was found to have sloughed. Stump now treated as an open wound. Final results good, however. Patient discharged well on Feb. 7th, 1884.

It will be noticed that out of five cases of Syme's amputation dressed antiseptically, as detailed above, only one healed without suppuration. In Case 16 the obviously deficient vitality of the parts led me to anticipate the unfavourable result, but as regards three at least of the remaining cases I am unable for the present to explain satisfactorily the failure of the dressing.

(To be concluded.)

ON THE TREATMENT OF SYPHILIS.[1]

BY JAMES WILSON, M.D.

THAT the general treatment of acquired, and particularly that of advanced, syphilis in this country is far behind that of the Continent cannot be denied, otherwise why should we be compelled to send cases there so frequently for treatment, and why should an English-speaking race so largely contribute to the support of those places where this specialty is so largely carried out, if our treatment in this country were what it ought to be, certainly what it might be if we more closely followed out the continental principles of treatment, and recognised that syphilis, like other diseases of a blood nature, must be thoroughly and systematically treated if we hope to effect a cure, to say nothing of preventing the terrible relapses so frequent in this disease. The remedies are all right—no fault is to be found with them; mercury and the salts of potassium, particularly the iodide, with their adjuncts, hold good in all countries where the disease is understood and rationally treated. But it is to their mode of application that we must look, and it is entirely, in my opinion, the mode of application that has made Aix-la-Chapelle so famous throughout the whole world for the treatment of syphilis. No doubt it has climatic and other surroundings, such as baths and waters, which in this country we shall never probably possess in a similar degree. Still, there is no reason why the treatment cannot be efficiently carried out in England, and that it should become the exception, and not the rule as it now is, to send bad cases there; and this opinion is not expressed by me without having carefully considered all the means at our disposal, as also from a long sojourn in Aix devoted to the study of the German treatment; and the marvellous results met with there have led me to this conclusion, and impressed me with the desire that it should be more fully carried out in this country than it is.

For a long time before going to Aix I had come to the conclusion that in this country we were far too fond of giving mercury by the mouth, which is the worst of all forms of giving the drug—certainly the most uncertain in its results, the most ineffectual in its operation, and the one most frequently followed by relapses; indeed, these are the cases that later on in life find their way to Aix, then the subjects of advanced syphilis, and that pass from the surgeon to the physician as legacies in our hospitals; and, indeed, I think the physicians here might reasonably complain that a disease in two of its stages essentially belonging to the surgeon, and when so much could be done by efficient treatment,

[1] An address introductory to a discussion at the Medical Society of Liverpool, Nov. 19th, 1885.

Digitized by Google

should be allowed to pass on to his department, when a much longer time for cure will be required, and when he has no other course to pursue than that of being compelled to deal with the shortcomings of his predecessors. One of the gravest mistakes made in the treatment of this disease is unquestionably the inefficient mercurial course in the first and second stages. Now, I cannot say I was greatly surprised to find my views as to the giving of mercury by the mouth confirmed by the German doctors, but I was struck by the fact that nearly all the cases coming to Aix for treatment had been those in which the drug had been administered by the mouth, and that it was rare to find cases there in which the treatment I am about to describe had been successfully carried out—namely, *inunction*.

Of all forms of giving mercury, that by inunction is the best; not the so-called inunction treatment of this country, however, in which a little mercury is applied, most frequently by the patient himself, to the inside of the thigh or armpit, for, say, a few days, and then discontinued altogether; or the wearing of a belt on which a little mercurial ointment has been spread; this may, and sometimes will, answer in children, but in adults it is totally inefficient and inoperative. For mercurial inunction to be successful the ointment must cover a large surface of the integuments, must be thoroughly and systematically carried out, and the skin must be prepared for the anointing by a bath daily, and, above all, must not, if possible, be performed by the patient himself. When, therefore, a case of syphilis presents itself to our notice in which this treatment can be carried out (for of course it could not be done during the stage of efflorescence), it is pre-eminently the best of all forms of giving mercury. Ample experience has proved the correctness of these views. For the successful treatment by inunction, however, three precautions are necessary:—Firstly, the skin must always be prepared for the absorption of the mercury, and the grey ointment (preferable in many ways to the oleate) must always be administered carefully, and in sufficient quantity; secondly, the system during the treatment must be maintained sound both as regards diet and hygienic surroundings; and thirdly, the inunction treatment must be carried out long enough.

With regard to the first point, that of the preparation of the skin for the absorption of the mercury, in general it is sufficient if the patient take a warm bath of from twenty minutes to half an hour's duration, at a temperature of about 95° or 96°. The body is to be well cleansed with soap, so that the skin is in a fitting state for the reception of the grey ointment. After the bath the patient is to be well rubbed, and a drachm of the ointment is then carefully rubbed in (by an experienced rubber if possible). I very much object to patients rubbing themselves, till I have satisfied myself that they have adequate skill and perseverance for the task, and know how to rub, and I absolutely forbid patients who are weak or have insufficient strength for the purpose. The ointment must be rubbed in with the entire surface of the hand, and with both hands conjointly. So that when, for example, the legs are subjected to the rubbing, the surfaces of the hands glide up and down simultaneously. Gloves, or a pad covered with leather are absolutely to be forbidden, otherwise much of the ointment, instead of penetrating the skin, is lost on the surface of the glove or pad. The accuracy of this fact is easily demonstrated by weighing such gloves after a few rubbings. The mercury is but slightly, if at all, absorbed by the surface of the hands, and absolute prevention is obtained by smearing the hands with soap or lard before the inunction. If due precautions are paid to these points the rubber need have no fear of evil consequences following to himself. The rubbers in Aix, who are in the habit of rubbing some dozen or more cases daily, seldom meet with any inconvenience in their daily vocation, being careful as to these matters of cleanliness and the anointing of the hands with soap. The rubbing should last twenty minutes—ten minutes for the one half of the member rubbed, and ten for the other; and the ointment is to be rubbed in with considerable pressure. I should have said that it is well to divide the ointment into two portions—one half, as above mentioned, for one leg, and the other half for the other. Supposing the legs to be the portions of the body on which the mercurial ointment is being applied, and on which it is always best to commence, the systematic treatment by inunction, sometimes less than a drachm of the grey ointment is sufficient to commence with—viz., two scruples (40 grs.). Twenty minutes is quite long enough for the arms and extremities; less for the trunk. Some patients cannot endure the breasts and abdomen being rubbed; in such cases the sides of the body and nates should be selected. It is of great importance that the rubbing be systematic, the different parts of the body being taken in order. For this purpose it is best to commence with the legs on the first day; on the second, both thighs; on the third, the abdomen and breast; on the fourth, the back; and on the fifth, both arms; reverting again to the legs on the sixth day. After the rubbing the patient should lie down or rest quietly for, say, one hour, after which he may go out and walk if the weather permit, or go about his occupation if not too laborious. I always direct my patients to drink a tumbler of Harrogate or Aix water once a day, if not twice; one tumbler in the morning before breakfast, and another about 12 o'clock or a little earlier. Sometimes in people whose skin is sensitive, or who are unduly hairy, the irritation caused by the rubbing and ointment occasionally sets up a little suppuration of the hair follicles, and painful pustules appear. This may be entirely prevented by first shaving the part, and as this condition usually occurs when it does take place on the thighs and legs there need be no difficulty in performing this slight operation. Well cleansing the parts with soap and water while in the bath is generally sufficient to prevent this condition of things taking place. It therefore becomes of the utmost importance that the parts anointed on the previous day should be well cleansed before a second rubbing, while it is always advisable to have recourse to a bath daily for the purpose above indicated, as well as to prepare the skin for the subsequent rubbing. Some people complain that a daily warm bath weakens and prostrates them. I do not think so myself if taken at the temperature indicated—viz., about 95°. Should it appear, however, to do so, then a bath every other day may be taken, though in such cases I would advise a little later on that a vapour-bath be had recourse to once or twice a week.

The second point indicated during a mercurial course is that the system be maintained by a proper and sufficient diet, and due regard paid to clothing and other hygienic surroundings. It is of the utmost importance during the treatment that the patient breathe fresh and pure air; and as the skin and not the lungs is entrusted with the absorption of the mercury, it becomes necessary that the patient should occupy large and airy rooms, and, so far as his strength will permit, take adequate out-door exercise and avoid the risk of catching cold. Most persons of ordinary intelligence may be trusted to guard themselves against this evil, though it is astonishing the difficulty that sometimes occurs to convince people of the importance of this, and further to make them carry it out by clothing suitably and properly adjusted. Then, as to diet, the food must be simple and nourishing, the patients living well, but not overtaxing the powers of the stomach, with absolute abstention from such articles as salmon, eels, mackerel, Finnon haddock, and salt kinds of fish, cheese, salads, and raw fruit. Stewed fruits may be taken, and a moderate use of wine or beer may be allowed in cases where patients are accustomed to their use. The drinking daily of one or two glasses of milk is to be strongly encouraged; indeed, I feel sure that in this country, no matter what form of mercurial administration is employed, whether internal or external, we do not give sufficient milk; in Aix the doctors insist upon milk forming a substantial portion of the daily food, and they have been fortunate enough to obtain a milk as nearly identical to human or mother's milk as it seems possible to get, obtained by a dry-feeding process, the cows never touching green food, but living on a preparation of corn, barley, and wheat-meal with bran, to which a little salt is added; with this mixture the cows are fed twice a day, the intervals being filled up by hay, which is placed in their mangers, of the best quality, and always at their use; they are further allowed to drink as much water as they like,—the result being that a milk highly nutritious and easy of digestion is obtained, which is, I think, at the present moment the nearest approach to human milk that has been produced. Patients from all parts of the world come to drink this milk, and all syphilitic patients are directed to drink as much as they possibly can fresh from the cow, three and four glasses being easily consumed at a sitting, and generally in the afternoon.

Another point to be attended to during the inunction, and indeed all forms of mercurial treatment, whether external or internal, is the state of the mouth. Scrupulous cleansing of the teeth and rinsing of the mouth with a wash made from the

Digitized by Google

acetate of alumina prepared by mixing alum with acetate of lead in adequate proportions, to which a little aromatic water may be added, is advisable. The formula I am in the habit of using is—acetate of lead, 240 gr.; powdered alum, 330 gr.; distilled water, 16 oz.; aromatic or peppermint water, 8 oz. Dissolve the lead and alum salts separately in the water; mix and stir well together; either filter or let the precipitate settle, and decant the clear solution, to which add the aromatic or peppermint water. It may be used diluted with water if necessary, and the mouth is to be regularly rinsed out from the beginning of the treatment to the end ten or twelve times a day, or even more, and in urgent cases during the night. By so doing salivation is prevented, and if by any means it should occur its ill effects are counterbalanced by the use of the mouth-wash. I might here say that preparatory to any mercurial treatment, whether external or internal, it is always well for any old stumps of teeth to be extracted, particularly if they are in the habit of giving trouble.

(To be concluded.)

CASE OF LYMPHO-SARCOMA IN THE GROIN.

OPERATION; RETURN OF THE GROWTH.

BY F. R. FAIRBANK, M.D., L.R.C.P. LOND.,
SURGEON, DONCASTER INFIRMARY;
AND
F. WALLIS, M.R.C.S. ENG.

THE case reported in THE LANCET of December 19th, 1885, from Westminster Hospital, as having been operated upon for recurrent lympho-sarcoma, is of sufficient interest to warrant a more detailed report of its earlier history.

For several years the patient had suffered from a small tumour in the right groin, below Poupart's ligament. This had given him no trouble, and he was advised by his then medical attendant to leave it alone. As it began to increase in size in the early part of the summer of last year, he sought Mr. Wallis's advice, who requested a consultation with Dr. Fairbank. On July 17th they together saw him. He was an emaciated young man, having an anxious look. He stated that during the last two months the tumour had increased rapidly in size. He had consulted a surgeon in the town where he had been staying, who offered the opinion that the tumour consisted of a hernia with a suppurating gland over it. Poultices were applied and an incision made, which gave vent to hæmorrhage, but nothing else. He then came under Mr. Wallis's care, who ordered ice to be applied locally until the consultation had been held. On examination a tumour was found in the right Scarpa's triangle, measuring about six inches in length by four inches in breadth. It was of the shape of the figure 8—two portions joined by a neck. The upper and deeper-seated portion was soft; the lower portion was firm and implicated the skin, which was of a deep red colour over it. The tumour was movable, and, with the exception of the skin over a part of it, was felt to be distinct from the surrounding tissues. The diagnosis was sarcoma, and immediate removal was recommended.

On July 21st, at his own home, in the presence of Mr. Wallis, Mr. J. Gelston, house-surgeon to the Doncaster Infirmary, and Mr. W. Nicholls, Dr. Fairbank removed the growth. Mr. Gelston administered the anæsthetic known by the letters A. C. E. A lozenge-shaped incision was made round the tumour, which enclosed the whole of the skin implicated. The tumour was found in the subcutaneous tissue, and entirely separate from the surrounding tissues, and external to the deep fascia. There was only one artery supplying it, and this was readily secured. The removal was very carefully and thoroughly carried out. The tumour weighed over 2 lb. When the operation was completed the patient fell into an alarming condition: breathing ceased, and the pulse was imperceptible at the wrist. Artificial respiration and faradisation were kept up for about two hours before he appeared out of danger.

The wound healed rapidly and well up to a certain point. In the centre, where there was the greatest tension, a part about the size of a florin remained open. The patient improved rapidly in general health, and was able to go away from home fourteen days after the operation. There was then no increase in the size of the wound, or any sign of other tumour. About Aug. 22nd, while at Ripon, he noticed a fresh lump in the lower part of his body on the right side, and in consequence came home to see Mr. Wallis. When Mr. Wallis then saw him the wound was about the size of a crown-piece, with the edges irregular, thickened, and hardened. A small tumour, about the size of a pheasant's egg, was noticed above Poupart's ligament. The wound increased rapidly in size. On Oct. 1st another consultation was held. There was then an open wound over Scarpa's triangle, the size of the palm. The edges were indurated and undermined. The floor of the wound was clean and glazed. The femoral vessels were only thinly covered. There was a tumour above Poupart's ligament, the size of a small hen's egg. His general health was then good. Subsequently to this he went to Westminster Hospital, and the case terminated as reported in THE LANCET of Dec. 19th.

Portions of the tumour from Scarpa's triangle were forwarded to Dr. Ernest H. Jacob of Leeds, who has supplied the following report of his examination: "The growth was of varying consistency, from that of a normal lymph-gland to that of encephaloid softness. One portion was adherent to the skin. Microscopically, in some parts the growth was ordinary-looking lymphoid tissue, but there was a large amount in which the cell element was in excess, and presented the appearances of lympho-sarcoma rather than lymphoma simple. There were also signs of caseation and breaking down in the softer parts."

Mr. A. A. Bowlby, of St. Bartholomew's Hospital, also has sent the following report:—"Microscopic description of tumour: It is composed mainly of cells, which are larger, more irregular in outline, and more granular than ordinary lymphoid cells or leucocytes. Here and there a little fibrous stroma may be seen and a few bloodvessels. It is evidently a round-celled lympho-sarcoma."

The report of Mr. Walter Arthur deals chiefly with the condition of the nervous and circulatory systems. It would be very interesting to read what was the condition microscopically of the soft parts removed from Scarpa's triangle, and what was also the condition at the time of death. This case is interesting specially as showing that a comparatively innocent enlarged lymph gland may assume malignant characters of most virulent description.

Doncaster.

INHALATION IN PULMONARY DISEASES.[1]

BY W. H. BLENKINSOP, M.D., M.K.Q.C.P.

IN the treatment of pulmonary diseases our efforts, as I need only in passing observe, are directed more or less to a threefold method of cure—(1) by the administration of internal remedies, (2) by the employment of various external agents, and (3) by the introduction of medicated vapours into the air-passages by the process of inhalation. I am desirous here of drawing attention more particularly to the last-named method, the importance of which was recognised by the older physicians, and was developed early in the present century by Scudamore and others, who severally recommended the use of iodine, chlorine, and tar vapours. In whatever way we regard the action of this special mode of treatment, the fact remains that it is by far the most rational, possessing many obvious advantages over others, particularly in phthisis, and being capable of much further development. Notwithstanding the generally encouraging results, however, of this aid to our other methods, there are certain details connected with its employment which are somewhat indefinite at present, and upon which I think we require a distinctly pronounced expression of opinion. Let me for convenience' sake place my observations under the following headings.

First, I find it of service in speaking of inhalation—which will be further discussed as we proceed—to include within it two allied processes—viz., vaporisation, where hot air or steam is generated, and fumigation, where drugs or scents are volatilised. As regards the last-named process, we are sufficiently conscious of its potency in destroying noxious odours and germs in a sick room; but as to its effect upon the air-tubes of invalids suffering from pulmonary mischief, there is little aid that we can hope to gain from it. For example, if a specific action is required upon the lungs,

[1] Paper read before the Harveian Society, Jan. 7th, 1886.

Digitized by Google

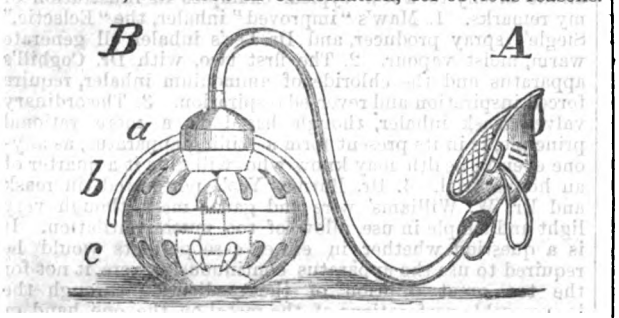
the continuous saturation of the room with a *powerful* strength of vapour tends to produce headache and other nervous conditions in many patients, with derangements of the digestive organs; whilst the attendants also, whether nurses or relatives, are much inconvenienced by the surcharged atmosphere. Few can be found to tolerate this, notwithstanding there are some amongst us who are much in favour of the plan. If, on the other hand, the strength of a vapour is minimised, to prevent unfavourable consequences, we should find the process of cure somewhat indefinitely prolonged, if it ever occurred at all. In one word, therefore, fumigation may be regarded as a serviceable accessory, when reasonably employed, through its purifying action on the surrounding atmosphere, and possibly also by its invigorating effect upon the patient. Vaporisation of *dry air*, to which I shall again allude, is that method which proves so strikingly useful, and offers the greater advantage over steam, in acute cases, where the system is also undergoing other treatment.

Secondly, our subject leads us to inquire what affections of the respiratory organs have been found to be benefited by these auxiliary modes of treatment. Amongst the more acute may be named bronchitis, pneumonia, laryngitis, and croup; of chronic cases, phthisis in its various stages, chronic bronchitis, and pneumonia, and circumscribed gangrene of the lung; whilst of a somewhat mixed variety are to be reckoned whooping-cough, asthma, influenza, hay fever, and many throat affections, including diphtheria.

Thirdly, the point has been much argued, although it still appears to remain an open question, as to whether dry or moist vapours, medicated or otherwise, should be used, either in the usual process of inhalation or where a warm atmosphere is needed around a patient in an acute attack of illness. In speaking of *dry* medicated vapour in connexion with the former, I refer to that which results by volatilising powders or tinctures, or by burning medicinal herbs in a suitable apparatus and without the aid of steam. During a somewhat lengthened experience I have noticed the evil effects of moist vaporisation, excepting only, perhaps, in cases of laryngeal phthisis. The air-passages by this method are charged with an undue amount of aqueous vapour, which renders the mucous membrane so sodden that the calibre of the air-tubes is lessened and much urgent dyspnœa is the result. The tissues also become relaxed, the respiratory function is interfered with, and suppuration is encouraged. I am borne out in this opinion by two very able authorities among others—Mr. Hamilton of Liverpool and Dr. Coghill of Ventnor,—whose views upon the subject correspond very nearly with my own.

In croup and other acute cases, where the process of steaming is now for the most part adopted, for the purpose of warming the atmosphere, many of the drawbacks already referred to present themselves, recovery being in consequence retarded. The use of heated air, therefore, as I have already stated, is of far greater service and more to be depended upon. And here let me recommend a modification of Messrs. Allen and Son's portable hot-air bath, which has been very ably carried out under my directions. At the bottom of the dome of the apparatus a plate of talc is inserted and made completely air-tight—a hot-air chamber being thus constructed, to the entire exclusion of any products of combustion. On the front of the dome is a socket, into which a tube with a ventilator at the end fits. This inlet tube is sufficiently long to prevent any indraught of combustible material from the lamp through the perforations required for the circulation of air around the latter. The air, passing through the chamber referred to and funnel head and tubes attached, heats the atmosphere within a bed tent with dry vapour, and thus aids in relieving feverish symptoms, dyspnœa, and cough, both directly through the air-passages, and indirectly through the skin. The dry or Turkish bath has for years been recommended on these grounds for the relief of phthisis; cough, expectoration, and blood-spitting having been materially influenced by its use.

I have, next, much to say in connexion with the various inhalers which have hitherto been employed in the administration of medicated vapours. Many are based on wrong principles, none are entirely faultless, and a large number are positively useless. The majority demand forced instead of easy inspiration—a function not readily performed in health, much less in disease. The natural mode of respiration, moreover, solely through the nostrils, is perverted, and in a manner reversed; and patients are directed to go through the not very easy performance—which, happily for themselves, they are as a rule unable to attempt—of drawing the medication into the mouth by a deep inspiration, and expiring it through the nostrils! Some of these inhalers generate moist vapour, to which I have already alluded. It is scarcely possible to determine in any what quantity of the prescribed material is absorbed, either on account of its dilution or loss into the surrounding air when used with steam, or in many instances by reason of its slight volatility when used on a sponge and attempted to be snuffed or gulped into the air-passages. In certain forms the medicated vapour is merely drawn into the mouth and puffed out again, as in smoking, without a particle ever finding its way even to the larger air-tubes. It is necessary that an inhaler should be as convenient and easy in its action as it is possible to contrive it for those whose respiratory functions have been enfeebled by illness; and that dry medicated vapour of known strength should at stated intervals be taken into the system, without any effort on the patient's part whatsoever, and in accordance with the natural method of respiration. For lack of an apparatus which should more or less fulfil the above requirements, and in the absence of sufficiently distinct ideas as to the most suitable remedies to be employed, we find that treatment by inhalation has in reality not advanced at the rate it should have done; whilst in many hands it has resulted altogether in failure. Dr. Burney Yeo, who recommends the *continuous* use of a special oro-nasal respirator inhaler, says, "we must not ask more of this method, or expect better results from it than it can possibly give." Now, as this has been less than I myself consider the system perfectly capable of performing, I find one more reason for repeating that it is still very imperfectly understood.



Of the various forms of inhalers in use it is necessary to allude briefly to a few typical examples in illustration of my remarks. 1. Maw's "improved" inhaler, the "Eclectic," Siegle's spray producer, and Dr. Lee's inhaler all generate warm, moist vapour. 2. The first two, with Dr. Coghill's apparatus and the chloride of ammonium inhaler, require forced inspiration and reversed respiration. 3. The ordinary valved mask inhaler, though based on a more rational principle, is in its present form a stifling apparatus, as anyone even in health may know who will give it a quarter of an hour's trial. 4. Dr. Burney Yeo's perforated-tin mask and Dr. W. Williams' wire and gauze mask, though very light and simple in use, allow of too much ventilation. It is a question whether in either case patients would be required to use the apparatus continuously, were it not for the too great dilution of the medication through the innumerable perforations of the metal on the one hand or the gauze on the other. 5. Siegle's spray producer requires much exertion in keeping the mouth continuously open, and is really more intended for throat cases. 6. In the chloride of ammonium inhalers the vapour which is drawn into the mouth practically seldom reaches the air-passages. Lastly, in all, the quantity of the remedy absorbed is quite uncertain, either in consequence of the dilution or the feebly volatile nature of many of the drugs prescribed for use. I may perhaps just add here that Dr. Yeo, in noticing Dr. Coghill's description of his respirator inhaler, remarks that the latter "does not cover the nose, but only the mouth, which is unadvisable, as the majority of persons breathe through the nose; and indeed it is desirable that they should do so. Dr. Coghill lays great stress on inspiring through the mouth and expiring through the nose, in order to secure a complete circulation of the medicated air. But this process would prove very tiring if attempted continuously." After a variety of experiments, I am able myself to offer an inhaler to the notice of the profession, which will, I trust, be found to remedy most of the drawbacks to which I have referred in connexion with those at present in use.

Briefly, my apparatus consists of two portions, connected by a flexible piece of tubing, as shown in the accompanying figure. A is an ordinary mask, with a communicating chamber beneath, containing sponge or felt. On each side are slits, in place of valved openings, and along the crest perforations for the escape of expired air. Elastic tapes worn round the ears or neck help to keep the mask over the nose and mouth. The vaporiser, B, about five inches in width, is in three sections, the lowest of which, *c*, contains a spirit lamp. Over this is the cover, *b*, surmounted by a chamber, which is used either as a receptacle for powders or for generating hot air, and is fitted at its base with a disc of talc. The two main segments are perforated for the admission of air in connexion with the lamp, whilst two curved

Digitized by Google

air-tubes communicate with the above-mentioned chamber.[2] Tinctures, when prescribed for inhalation, will be poured over the felt at the base of the mask. These will become volatilised by the hot vapour passing from the air-chamber of the vaporiser. When powders are used they will be placed in the hot air receptacle of the latter, to be there vaporised, the fumes being inhaled with ether, chloroform, or any tincture, if so desired. This apparatus is easily handled, and can be conveniently used in any position either on the table or on the lap.

Lastly, in reference to treatment, I have already said that in *acute* pulmonary affections the diffusion of heated air around the patient was all-sufficient when other methods of cure were being at the same time adopted. Fumigation may be had recourse to if it should be considered to be of any service; but inhalation proper would, I need scarcely observe, be inadmissible from the dyspnœa already present. Among *chronic* cases, phthisis, gangrene of the lung, and chronic bronchitis and pneumonia are all, under their various conditions, benefited by antiseptics, astringents, antispasmodics, sedatives, or stimulants, of which we have a long array. In the *mixed* varieties also many of the above are found to be extremely serviceable, particularly when used in combination with a heated dry atmosphere. Our object in general is to reduce inflammatory symptoms and allay irritation of the air-passages; to destroy or arrest activity in the specific organism present, as in phthisis; to promote a healthy condition of cavities; and prevent absorption of putrid secretions which are constantly exercising their baneful influence on the blood. These several conditions are readily met by suitable remedies taken directly into the respiratory organs, as well as by constitutional treatment. Inhalants are, like remedies administered by the mouth, best used in combination, for obvious reasons.

Many patients complain of a greater difficulty in coughing up phlegm after inhaling. This may be due to their continuing a habit which has become needless, or from a preternaturally dry condition of the air-tubes during convalescence, which soon, however, passes off. Most drugs in the Pharmacopœia can, with due precautions and a suitable apparatus, be inhaled with advantage. I am myself carrying on a series of experiments with the view of determining the exact doses to be used in all cases, and the time each inhalation should last with dry medicated vapour.

In Squire's fourth edition of the Pharmacopœias of the London Hospitals, upwards of fifty combinations may be found of drugs recommended for purposes of inhalation. The majority are used with *steam*, but although the quantity to be mixed with the latter is given, it is impossible to say how much is taken into the lungs. (This last could only be done by directing that inhalation should continue for a certain length of time, with a medium strength of solution at a given temperature.) It is necessary in every case, at starting, to begin with small doses, particularly when a drug is volatilised by dry heat. Thus, for instance, a strength of seven minims of dilute hydrocyanic acid would scarcely be prescribed in the latter case, although a teaspoonful, of a drachm to an ounce in strength, to a pint of water at 80° F., is recommended in the Pharmacopœia for each inhalation—whatever this may mean. It would be a long and suffocating process, for one thing, to attempt to take into the lungs the vapour of a whole pint of water. About one-half the dose administered by the mouth is generally a fair one to start with. Dr. Wagner, of Buda-Pesth, allows his patients to inhale until a burning sensation is produced in the chest, but I think it better to watch the effects in each case at starting, and then to prescribe accordingly. It is useful for patients to inhale soon after rising, and also just before retiring to rest, as well as two or three times in the day, and at night if awake. Even with the dry process some substances take longer volatilising than others; it is needful, therefore, after prescribing a given strength of a drug, to regulate the heat of the vaporiser. Dr. Carrick Murray, of the Northern Counties Hospital for Diseases of the Chest, considers half an hour twice a day sufficient for the use of the inhaler, and also that twenty minims dropped on at once is sufficient for two days' use. How are we to reconcile this with the instructions of other authorities, say Dr. Coghill and Dr. B. Yeo—the former of whose respirator inhaler Dr. Murray was adopting—for the continuous use of their apparatus?

It would be impossible to enter into details here regarding every remedy found to be useful in pulmonary diseases; let it suffice therefore, in conclusion, to name merely a few. Carbolic acid, creasote, terebene, eucalyptus, thymol, pine oil, as well as iodine and iodoform, are amongst those most frequently used, either in combination with each other, or with antispasmodics, sedatives, &c. In Germany rabbits inoculated with tubercular matter were considered to have been kept free from tuberculosis by breathing an atmosphere saturated in benzoic acid. According to Dr. Cottereaux of Paris, chlorine gas is a specific for every form of phthisis. There are many cases in which sulphur medication has proved of great value, those engaged in the manufacture of sulphuric acid being also stated to be protected against phthisis. Dr. Jaccoud of Paris believes much in the curative effects of the pure creasote of the beech, and gives details of cases. Terebene and carbolic acid are also advantageously employed by the mouth to check intestinal infection from the sputa swallowed so frequently by patients, the lymph follicles of the intestines being so very prone to tubercular infection. Lastly, iodine proves most useful in the second stage of phthisis, and, with carbolic acid, in the purulent expectoration accompanying pneumonia; it has also a soothing effect when combined with ether.

[2] Further details will be provided later on by the manufacturers.

CASE OF THORACIC ANEURYSM RELIEVED WITHOUT OPERATION.

BY EVERARD HOME SAUNDERS, M.R.C.S., &c.,
SURGEON, ROYAL NAVY.

CASES of thoracic aneurysm so seldom being relieved by constitutional treatment or operative interference, the following, under observation here since January, 1885, which by the kind permission of Fleet-Surgeon D. O'Connor, M.D., R.N., I am able to forward, will doubtless prove of interest to the profession and worthy of record.

William F——, aged fifty-three; a naval pensioner, twenty-four years' service, the larger part of which was passed on foreign service; a widower; fair complexion, healthy appearance, of abstemious habits; good family history; has always enjoyed good health; no history of syphilis, gout, or rheumatism. Three years ago the man received the following injuries by a cart on which he was standing overturning, throwing its contents (a ton of copper sheeting) on him, and severely contusing the left hip, right shoulder, and chest, and fracturing the left tibia and fibula at the lower third. In January, 1885, he first commenced to complain of pain affecting the right lung at its apex, together with slight cough and bronchitic expectoration. These symptoms soon subsided, and he returned to duty, that of a labourer. In the following May he presented himself, suffering from laryngeal cough, giddiness in the head, and pain of a gnawing character through the right chest to the scapula, over the right shoulder-joint, and extending up the side of the neck, face, and right temple. He was unable to lie down or sleep on account of the pain, together with a feeling of impending suffocation, nor was he able to undergo the slightest exertion without discomfort. There was no complaint of dysphagia, no numbness or tingling sensations in the limb, no swelling or œdema of the right arm. He had never spat blood.

On examination there was found undue prominence over the right sterno-clavicular articulation; also dulness on percussion extending from the clavicle downwards to the upper border of the third rib, laterally from the left border of the sternum for a distance of two and a half inches

Digitized by Google

towards the right shoulder-joint; visible pulsation in the right subclavicular region, and a pulsating tumour of a rounded form situated behind the right sterno-clavicular articulation. The right pupil more dilated than the left; the right radial pulse less marked and feebler than that of the left side. There existed a patch of cutaneous congestion over the most prominent part of the tumour. No bruit; heart-sounds normal; no distension of superficial veins.

The symptoms becoming aggravated, the patient unable to assume the recumbent posture, pain increasing in severity, and not being able to obtain sleep, he was sent to the Royal Albert Hospital, and admitted under the care of Mr. Leah. Rest in bed, starvation diet, or, in more pleasing words, a modified Valsalva's treatment, subcutaneous injections of morphia to relieve the agonising pain and procure sleep, and the internal administration of the iodide of potassium up to fifteen grains three times a day, formed the treatment. As the patient was unwilling to undergo an operation (which was merely suggested to him), and his bed was required, he was discharged on June 30th, 1883. Although no appreciable alteration took place as regards the tumour and the symptoms whilst an inmate of the above institution, he from the time of his discharge steadily improved. The treatment with the iodide has been continued. There appears to be no doubt as to the present condition of the tumour, which is decreasing in size, and presumably undergoing spontaneous cure.

On reference to several works on the subject of aneurysm, I find but few recorded cases where such marked benefit has taken place in so brief an interval under constitutional treatment—viz., those of Bouillaud, Tuke, Andral, Nélaton, and a more recent one recorded by Dr. Roberts of Manchester. Whether the commencing lamination (primary) took place during the patient's sojourn in hospital, whether entirely or in part due to the restricted regimen, to the iodide of potassium (which, I believe, is now credited with the power of increasing the coagulating powers of the blood), or to all these circumstances combined, it would be hard to form an exact opinion; but the case teaches us that in favourable subjects we may expect now and again to derive marked benefit, if not permanent cure, without operative interference, which is only done in desperate cases as the last resort, and almost invariably proves fatal.

ST. THOMAS'S HOSPITAL.

PERINEPHRITIC ABSCESS DUE TO RENAL CALCULUS; NEPHROLITHOTOMY; CURE.

(Under the care of Dr. STONE and Mr. JOHN CROFT.)

THE following case is well worthy of record. For years a patient who had been suffering from the symptoms of renal calculus, but without hæmaturia, had refused operation, only giving her consent after the evacuation of a large perinephritic abscess. How long the calculus had been forming it is not possible to say, but the evidence of its presence extended over a period of several years, during which she had frequently been incapacitated from the active duties of life and subjected to much pain and impaired health. It is somewhat strange that there had not been greater change in the structure of the kidney as the result of inflammation, but recovery with a useful kidney appears to have been complete.

E. G——, aged thirty-eight, married, was admitted into Christian ward, under the care of Dr. Stone, on Sept. 18th, 1885, and left Feb. 16th, 1886. Family history: Parents dead, causes of death unknown. A brother is said to suffer from stone in the bladder; a sister complains of pain in the region of the bladder, and a son of the patient is said to be "disposed to stone," being troubled to pass his urine. The patient has had trouble ever since she was a child in passing urine, with pain in the loins; but the symptoms did not thoroughly manifest themselves until 1871, when she came under the care of Dr. Stone, and was afterwards twice admitted into the hospital with the same symptoms, but refused operation. Her present trouble commenced at Christmas, 1884, when she had a slight miscarriage, a feeling of something in the bladder when walking, pain in the region of the right kidney, with pain and difficulty in passing her urine, which has been thick and very high coloured. No history of hæmaturia.

On admission she was a fairly well nourished, rather sallow woman, complaining, in a peevish tone of voice, of pain in the abdomen. This pain begins in the right lumbar region and passes through the groin to the right labium; it also passes down the front of the right leg as far as half-way down the shin. There is always some pain present, but she is liable to exacerbations of a cutting character. The right lumbar region is fuller than the left, and a soft round swelling in the region of the kidney can be indistinctly felt; in this position and in the right hypochondrium there is great tenderness. The rest of the abdomen appears normal. No enlargement of liver or spleen. Heart and lungs normal; pulse 80; tongue clean; appetite fair; bowels regular; skin normal. Temperature 99°. Urine acid; only a small trace of albumen; under the microscope there is a large quantity of pus cells, but no blood; deposit of urates and phosphates; sp. gr. 1030.

Sept. 21st.—Feels better for the rest, but does not sleep well. Complains of nausea, and is thirsty. Passes urine about three times in the day; complains of scalding; there is some difficulty in micturition, but when it has once commenced there is no further difficulty. Evening temperature has varied from 99·2° to 100·4°.

On the 26th the swelling in the abdomen had extended to the umbilicus; the abdominal muscles were very tense. She had a sharp attack of pain on the 23rd, and on the 24th there was no evidence of any pus in the urine. From this time until Nov. 4th there was no improvement, the temperature was usually normal in the morning, and two or three degrees higher in the evening. Her tongue became red and sore, the appetite failed, and there were slight attacks of looseness of the bowels. Several times there were attacks of pain in the right groin, and it was noticed that the swelling continued to increase until the above date, when fluctuation was found above the crest of the ilium, about two inches behind the anterior superior spine. The patient was placed under chloroform, and Mr. Battle opened the abscess at the point at which it was presenting. A large quantity of thick creamy pus escaped from the incision, and the finger when passed into the abscess cavity could be moved freely in all directions without touching the wall of the cavity, excepting on its outer aspect. Its full extent upwards could not be ascertained; downwards it extended to Poupart's ligament, and inwards to the mesial line. Antiseptic dressings were applied after syringing the cavity and the insertion of a drainage-tube. The bladder was also carefully explored with a sound, but no evidence of disease discovered. After this, until the 12th, the temperature was normal. An attempt was made on that day to reach the calculus by means of long probes and catheters, but the position of the opening and its distance rendered the attempt unsuccessful. In the evening the temperature rose to 100°. The discharge continued free, though lessening in quantity, and the temperature normal, but there was little improvement in the general symptoms, and she was losing flesh.

On Nov. 21st Mr. Croft operated. The patient having been placed under ether, the opening was enlarged upwards and the sinus examined. It extended downwards towards Poupart's ligament, and upwards towards the kidney; the muscles and fasciæ over it, which were much matted, were incised upwards, and another incision made at right angles to this. When the kidney had been bared fluctuation was felt in it, and the insertion of an exploratory needle gave exit to some thick pus. A longitudinal incision was made down to the pelvis of the kidney, in which a calculus of somewhat dumb-bell shape was found and extracted in two pieces. The wound was then thoroughly syringed with chloride of zinc, the kidney packed with iodoform gauze, and a large drainage-tube passed to the bottom of the sinus. Silk sutures were inserted, and iodoform, salicylic wool, and a pinewood-wool bag applied. This dressing was to be

Digitized by Google

changed every four hours. After the operation the temperature was 95°, gradually rising to normal at the end of twelve hours, when the pulse was 100, weak, and compressible. Vomiting lasted until the next day. She slept after the administration of morphia. Nutrient enemata were given every two hours until 2 P.M. of the day following, and then every four hours.

Nov. 24th: The urine was very smoky, and the temperature subnormal, so the dressing was changed to chlorinated soda lotion. From this date there is little to record, beyond occasional slight attacks of pain in the wound and gradual diminution in quantity of discharge. The temperature rose to 101° on the day after the operation, but became normal next day, and remained so throughout with one or two unimportant exceptions. The albumen (which had never exceeded one-tenth in amount) and the pus disappeared from the urine. Her general condition rapidly improved, and when she left the hospital she was better in health than she could remember to have been before. The calculus consisted of two parts—the larger, oval in shape, measuring one inch by two-thirds of an inch, joined by a narrow neck three-fourths of an inch long to a smaller part, also of somewhat oval shape, and measuring three-fifths by one-third of an inch; when dried it weighed about fifteen grains and a half. On section it was found laminated without evident nucleus. Chemical analysis showed the central portion to consist mainly of uric acid, with oxalate and phosphate of lime. The outer part was composed to the extent of nearly one-half of phosphate and oxalate.

NOTTINGHAM GENERAL HOSPITAL.

PUNCTURED WOUND OF BUTTOCK, FOLLOWED BY TRAUMATIC ANEURYSM; OPERATION; CURE.

(Under the care of Mr. JOSEPH LITTLEWOOD.)

G. H ——, aged fifteen, was admitted on the afternoon of May 8th, 1885, with a punctured wound in the left buttock, which was thus inflicted: He was seated on a form at school with some other boys. The one on his left hand was engaged in sharpening a pencil with a pocket-knife, and he was "playing" with the one on his right, who took up a ruler to strike him. To avoid the blow, he made a sudden movement towards the left, and received the blade of the knife in his buttock. The blade measured two inches and a half long. He was said to have lost a great quantity of blood at the time, which was stopped by a pad of lint and perchloride of iron, and he was then brought to the hospital.

On admission, a small incised wound barely half an inch long was found, its long axis lying across the position of Nélaton's line, posterior to the great trochanter. Another measurement was taken in order to determine its position with respect to other anatomical landmarks. Thus, a line drawn vertically downwards from the anterior superior spine of the ilium, with the limb in a straight line with the body, met one drawn horizontally round the outside of the buttock from the wound, exactly three inches below the anterior superior spine; and the length of the horizontal one between its point of junction with the vertical one and the wound was five inches and a half. The boy had not suffered much from the loss of blood, and the hæmorrhage had absolutely ceased, not a drop of blood now issuing from the wound. A pad and bandage were applied.

May 9th.—He complained of a good deal of tensive pain, so the wound was dressed. There was some hardness and swelling in the situation of it, which was quite dry and almost healed. A piece of dry lint kept on by strapping was applied.

11th.—The wound was completely healed; the swelling was larger and harder, and much ecchymosis had appeared over it.

12th.—Pulsation was noticed in the swelling for the first time.

13th.—There was now a large, hard, ill-defined swelling, the size of a cocoanut, occupying as nearly as possible the centre of the left buttock. It pulsated distinctly with an expansile beat, and on auscultation a bruit could be clearly heard. Most of the pulsation and by far the most marked area of it lay above—i.e., nearer the crest of the ilium than the wound. Much discolouration of the skin was now apparent, and it was curious that it hardly extended at all towards the thigh, but seemed to have spread almost entirely in an upward direction.

14th.—The size of the swelling, its pulsation, and bruit had all increased, and an operation was decided on.

15th.—Chloroform having been administered, Mr. Littlewood proceeded to perform the operation of laying open the aneurysmal sac and tying both ends of the artery in the wound. A short incision was made through the skin and fat over the most prominent part of the tumour down to the gluteus maximus, which on being reached was seen to pulsate and bulge through the edges of the wound. An incision large enough to admit three fingers was then made through the muscle, which was followed at once by a rush of arterial blood. With the fingers in the wound, which somewhat checked the flow of blood, an endeavour was made to find and compress the proximal end of the artery so as to arrest the hæmorrhage before completely laying open the sac. This, however, could not be done. The wound was then rapidly enlarged in an upward and downward direction to the extent of six inches, and the contents of the sac turned out. Rapidly as this was done, the quantity of blood lost was excessive and the patient became faint. An abdominal tourniquet was then applied, which completely arrested the bleeding. The distal end of the vessel was found without difficulty and ligatured, but the proximal end was only discovered after a long search. It was lying just within the great sciatic notch, and after some difficulty was tied. There was a considerable separation between the divided ends of the artery. After both ends had been secured (catgut ligature being used) and portions of loose coagula removed, the wound was closed with wire sutures and a drainage-tube put in. The operation was performed under the spray and carbolic gauze dressings used.

16th.—Had rallied fairly from the shock, and was taking fluid food well. Wound dressed; distended with blood-clot. No sign of hæmorrhage. Some of the sutures were removed.

17th.—Wound dressed again. There was a quantity of dark-brown-coloured discharge and small lumps of breaking-down blood-clot issuing from it. The remainder of the sutures were taken out and the wound thoroughly syringed with a 1 in 40 solution of carbolic acid. The temperature this morning was 102·8°. He complained of no pain; he was delirious during the night, but took fluid food well.

18th.—The wound was gaping widely, and had a by no means healthy appearance; still much dark-brownish clot in it, with an offensive discharge. Syringed out as before, and iodoform sprinkled into the bottom of the wound. Carbolised gauze dressing and spray continued.

The wound gradually discharged the remnants of clot, and began to granulate feebly. The spray and gauze dressing were discontinued, as they did not appear to promote its healing. Various dressings were used, as sulphate of zinc lotion, dry boracic lint, and perchloride of mercury wool. A generous diet with wine was given, but the progress in the direction of healing was of the slowest kind, and when he left the hospital in the middle of July a wound of considerable size still remained. There being scarcely any improvement during the last five weeks, and his parents being well to do, Mr. Littlewood felt no hesitation in sending him to his home, which was a few miles out of Nottingham, and when he saw him the first time afterwards a marked change had taken place, the wound being more healthy in appearance, and the large gap in the gluteus muscle, which had shown no signs of healing in the hospital, was rapidly filling up. He was seen six or seven times, and each time the improvement was marked and his general health improved—so much so that he was quite well at the beginning of September, with the exception of some stiffening about the hip; this, however, had quite gone when he called at the hospital a short time ago.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY-ROAD.—On the 15th inst. a new wing to this institution was opened by H.R.H. Princess Beatrice, with great ceremony, and in the presence of a large number of the friends of the hospital. The annual meeting was subsequently held, when the report for 1885 was submitted. It showed that 7567 out-patients had been treated, and that the year's subscriptions had amounted to £5026. The four wards in the new wing are to be named as follows: the Victoria, the Princess Beatrice, the Princess of Wales, and the Shaftesbury. The hospital was founded by the Duke of Kent in 1814.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuberculosis of the Skin.—Paracentesis for Bronchiectasis.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair. A very good discussion took place on the second paper, the meeting being prolonged till 10.40 P.M.

Dr. HEBB contributed a paper on a case of Tuberculosis of the Skin, which was communicated by Mr. G. Cowell. A strumous boy, under treatment in Westminster Hospital with supposed Barbadoes leg, was seen by many visitors to the International Medical Congress, and no exception was taken to the diagnosis. The boy had never been beyond the environs of London. He died two years later (aged eighteen) of a bronchial affection, and a portion of the thickened skin was secured for microscopical examination, with the following result:—General hypertrophy of skin; dermis thickened from overgrowth of its connective tissue and the presence of collections of lymphoid cells; in many places there are aggregations of both large and small lymphoid cells, and among them numerous giant-cells, the spheroidal masses thus formed being practically indistinguishable from tubercles such as are found in the liver and kidney; in the lymphatics a red staining shows the presence of small bacilli in great numbers, colonies being also found around the aggregations of lymphoid cells. The case is compared with one reported by the late Dr. Tilbury FOX, where the appearances and history were similar, but the microscopical specimens showed no trace of tubercle.—Dr. RADCLIFFE CROCKER said the question was whether this was a unique case or not. Lupus, scrofuloderma, and true tubercular ulceration were three conditions with which the case described might be compared. With the last mentioned it had no resemblance. But it was known that lupus of the legs did lead to elephantiasis of the limb affected; the elephantoid condition was probably the pathological result of obstruction of the lymphatics. Kaposi alluded to cases of elephantiasis following lupus in which the secondary changes masked the lupoid characters; the present case might have been an illustration.—Dr. THIN related the case of a lady suffering from a peculiar limited swelling of the back of the hand that looked something like Barbadoes leg; it was certainly not elephantiasis, and was limited to the carpus and knuckles. He thought it might have been similar to that described by Dr. Hebb. The "anatomical" tubercle resulting from post-mortem wounds had been shown by investigators in Paris and Berlin to be sometimes associated with the growth of tubercle bacilli. He was also struck with the remarkable fact that conditions clinically widely different from one another should be due to one and the same cause. The different clinical pictures caused by trichophyton tonsurans bore some analogy to this.—Dr. HEBB replied that, although many observers saw the case, no one suggested lupus as the nature of the disease; and Kaposi asserted that there was no difference between lupus of the leg and face.

Dr. THEODORE WILLIAMS and Mr. RICKMAN J. GODLEE communicated a conjoint paper on two cases of Bronchiectasis treated by Paracentesis, with remarks on the mode of operation. The first case was that of a gentleman aged sixty-seven, who had suffered for two years from chronic bronchitis and emphysema, and six months later had dry pleurisy of the left lung. After the pleurisy the expectoration, before moderate, became profuse and somewhat fetid, the cough more and more harassing, and although Malvern and Bournemouth were visited and a great variety of antiseptic treatment was tried, he obtained no relief. On Feb. 3rd he was seen by Dr. Williams, who noted the existence of a bronchiectasis in the lower lobe of the left lung, the pleura of which was adherent. Tubular sounds were heard over two small areas, neither exceeding a half-crown in circumference, in the eighth interspace. At the request of Dr. Williams, a puncture was made by Mr. Godlee into the first area with an aspirating trocar and cannula. Under antiseptic precautions the cavity was opened and a drainage-tube inserted. The result of the operation was that the cough nearly ceased, the expectoration, which was for a few days pneumonic, diminished from one pint a day to a few pellets and became free from odour, and the patient gained flesh rapidly. At the end of six weeks the discharge ceased, the channel closed, and the wound healed up. Examination of the chest showed complete disappearance of tubular sound from the second area as well as from the first, and further shrinking of the chest wall. The patient at the close of nine months after the operation remained free from cough and expectoration, and was able to walk four miles at a stretch. The second case was that of a girl aged twenty-one, who, ever since an attack of typhoid fever, had had troublesome cough and copious expectoration, gradually increasing in quantity and becoming more and more fetid. She had had hæmoptysis three times; on one occasion amounting to a pint. Examination of the chest showed several bronchiectases, two of which gave rise to very coarse râles over areas about the size of a half-crown in the sixth and seventh interspaces in the axilla; a third area was detected in the eighth space below the scapular angle. At first the patient improved under antiseptic treatment, the expectoration diminishing and becoming less fetid, but after a while these measures ceased to give relief, and an operation was decided on. On June 29th, at Dr. Williams' request, Mr. Godlee passed a small exploratory trocar successively into each of the three marked spots and, obtaining no result, inserted a large-sized aspirating trocar and cannula into the seat of the first puncture in the sixth interspace. But an attempt to cut down on the cavity failed. A second operation was performed on July 16th, and after some exploratory punctures Mr. Godlee, with antiseptic precautions, cut down on and laid bare the eighth rib, and excised about an inch of it in order to approach nearer to the bronchi before attempting to open them. The trocar and cannula were then passed to a depth of five inches, and Mr. Godlee cut down along the cannula and inserted a drainage-tube. The wound gradually healed up and the patient left the hospital at the beginning of September considerably improved, the cough slight, the sputum having diminished to about three ounces a day, and being only occasionally fetid. The presence of bronchiectases in other parts of the left lung, and possibly also in the right lung, precluded such complete success as was obtained in the first case. A short account was then given of four other cases of bronchiectasis treated by tapping, in all of which the position of the cavities had been recognised and successfully punctured, but owing to the presence of other bronchial dilatations the success was only partial in these cases. The arguments in favour of the operation are: 1. The tendency to death by septicæmia in some form, unless proper drainage is effected. 2. The reduction in the amount of expectoration, this being due, not only to the removal of the matter, but to the disappearance of the effects of its irritation on the healthy bronchi. 3. The invulnerability of the lung tissue, it being proved that punctures of this tissue give rise to little or no disturbance to the part or to the system generally. The difficulties of the operation are principally those of diagnosis of the exact positions of the bronchiectases: (1) from the presence of emphysema; (2) from the reverberatory character of their auscultatory sounds, which renders exact localisation very difficult. Paracentesis of bronchiectases seems to be indicated under the following circumstances: 1. In cases where antiseptic treatment of all kinds has failed to correct the fetor of expectoration, and to allay the harassing nature of the cough, where death by septic pneumonia seems imminent. 2. Where the evidence goes to prove that the bronchiectases are confined to one lung, are situated in the lower lobe, and have overlying them an adherent pleura. It is not indicated where multiple bronchiectases exist in both lungs, where they are surrounded by emphysema, and where the pleura is non-adherent.—Dr. GOODHART showed two recent specimens of bronchiectasis, which he considered lent force to the remarks in the paper on the difficulty of diagnosis. One of the specimens came from a boy aged twelve, at the base of whose right lung physical signs of pleuritic effusion were detected during life, but nothing was done owing to the signs of cerebral mischief. At the necropsy a cerebral abscess was discovered, and a pea was found in the bronchus of the diseased lung, which was in a state of consolidation, but riddled through with abscesses. The other specimen came from a woman who had all the signs of an acute pneumonia. At the right apex there were signs of consolidation; at the angle of the left scapula were sharp râles and harsh inspiratory murmur, which was regarded as probably indicative of pneumonia. At the necropsy pneumonia of the right upper lobe was found,

Digitized by Google

but in the left lower lobe a sacculated condition of the bronchial tubes was discovered. The symptoms and signs were of equivocal character in many cases of bronchiectasis. He had seen four or five of such cases in the course of the past ten years. He agreed that the presence of emphysema was a bar to the operation, for it masked the condition of things altogether. To diagnose adhesion of the pleura was almost impossible. The best cases for operation were those of bronchiectasis associated with chronic pneumonia or fibrosis of the lung. Many cases of bronchiectasis were never associated with fetor from first to last. Fetor was, in his opinion, always a question of some disintegration of the lung.—Dr. PERCY KIDD said that in the second case related in the paper the hæmoptysis was very alarming, and did not cease until the tube had been taken out. In some cases of bronchiectasis the development of fetor was associated with the onset of the signs of pleurisy; this might be explained in various ways; one explanation was the spread by contiguity of inflammation. In a case that had been under his care the illness began with "congestion of lung" eighteen months before; chronic bronchitis had existed ever since, but at the angle of the right scapula there were marked signs of a cavity; later on septic infection appeared, and was complicated with phlegmonous erysipelas. At the necropsy the case was seen to have been one of chronic pneumonia with cavities—none, however, larger than a blackbird's egg. Operation in this case was proposed but not carried out, and it could not have been of much good. Referring to the difficulties of diagnosis of bronchiectasis, he mentioned a case in which the bronchial dilatations were supposed to exist on one side, and post-mortem examination showed that the other side was also affected, though it had yielded no corresponding physical signs. The diagnosis of adhesions of the pleura was also exceedingly difficult, and he had found adhesions to be absent even where there was retraction of the parietes. He had seen three fatal cases of abscess of the brain resulting from suppuration in the lung. As to the diagnostic importance of membranous shreds in the expectoration, he could not bear out Dr. Williams' experience. Operative interference would prove unsatisfactory in intense cases of bronchiectasis. In other cases, where operation seemed favourable, the patient often made a good recovery with mere antiseptic non-surgical treatment. A case of a pulmonary abscess occurring after childbirth illustrated this forcibly.—Dr. CAYLEY believed that operation was most likely to prove successful when the bronchiectasis was surrounded by solid lung, and the pleura was then most probably adherent. Operation, in his opinion, was dangerous when bronchial dilatation was not so associated. The mode of death by abscess of the brain was very frequent in these cases; the abscess was solitary and chronic, and therefore peculiar. Next to ear disease, suppuration in the lung was by far the most frequent cause of cerebral abscess.—Dr. C. Y. BISS considered that suppuration in the lung should be treated in the same way as purulent collections elsewhere in the body. Speaking of the danger of septicæmia, which was real, he showed how in cases of bronchiectasis, by virtue of the tubes being constantly bathed with offensive material, there was a degree of immunity from septicæmia. Brain abscess might occur without operation in these cases. From his experience he would say that the danger from hæmorrhage could not be great, for the hæmorrhage had been small in all the cases he had seen. It had been said that the cut ends of ribs afforded an ingress for septic matter; there was no ground for that assertion, for the removal of portions of ribs in empyemata was now of very frequent occurrence, and yet septic infection was rare in such cases. He thought that inversion to get rid of an excessive amount of secretion threatening suffocation was a valuable mode of treatment if the emergency arose. The liability to recurrence of bronchiectatic cavities should be borne in mind when conferring with patients about operation.—Dr. T. BARLOW spoke of the extreme difficulty of diagnosis in some cases of bronchiectasis. He referred to a case which was almost a reproduction of one of the specimens shown by Dr. Goodhart. There had been impaction of a pea in one bronchus; the lung was riddled with cavities. During life there was almost no breath sound and very considerable dulness. In some cases of aneurysm, too, he had observed the same physical signs, and post-mortem examination had revealed bronchial dilatations.—Dr. COUPLAND also spoke of the difficulty of diagnosing bronchiectasis, and mentioned two cases in which pleural effusion was diagnosed, but bronchiectasis was found after death. The expectoration of a piece of bone in another case showed that what had been diagnosed as pleural effusion was really a solid lung in which a cavity had formed below the obstruction of a bronchus by the bone; this patient recovered without operation. Suppuration and gangrene of the lung might be induced by a suppurating bronchial gland, which opened, on the one hand, into a bronchus, and, on the other, into the œsophagus. Particles of food passing from the food-passage into the lung was no doubt the cause of the gangrene.—Mr. A. PEARCE GOULD said the conclusions of Mr. Godlee would secure the support of all surgeons. If physicians were unable to diagnose with certainty, there was also a corresponding difficulty for the surgeon. It was exceedingly difficult to estimate the distance from the surface of any cavity; the conductivity of sound between the cavity and the site selected for puncture must vary considerably with the nature of the interposed tissue. He recommended Dieulafoy's aspirator as an exploring instrument, the surgeon making a vacuum as soon as the needle has passed through the parietes. He could not agree with Dr. Biss that there was no danger of hæmorrhage.—Dr. BISS explained that, considering the theoretical danger of hæmorrhage, he had been surprised that hæmorrhage had been so slight; he did not assert that there was no danger.—Sir ANDREW CLARK congratulated the authors on their success in the first case especially, which had been under his own treatment a good many years ago. The patient was a dyspeptic, who developed general bronchitis about three or four years since, supervening on which there came a dry pleurisy of the left side, which persisted, but was unaccompanied by effusion; the base of the left lung became consolidated; the bronchiectatic condition of the right lung remained. The patient became subject to convulsive paroxysms of cough, during which he expectorated large quantities of mucopurulent material. For a time he got neither better nor worse, and then was lost sight of. He was glad that Dr. Williams had in the paper given the further course of the case. As to the value of surgical treatment of cases of bronchiectasis, he considered that the cases of operation were not sufficiently numerous to afford a definite judgment, but there could be no question that operation often affords great relief, and sometimes even a possibility of complete cure. With regard to the difficulty of making a diagnosis of adhesions, he was of opinion that the presence of dulness, diminished vocal fremitus, diminished vocal sounds, and resonance were almost certain evidence that adhesion had taken place. As to the diagnosis of bronchiectasis, he thought the difficulties were not so great as had been made to appear. If there were abundant expectoration with severe fever, with the presence of cords or leashes of elastic tissue in the sputa, and the absence of areolar elastic tissue, he would have no doubt that he was dealing with a case of bronchial dilatation. With regard to hæmorrhage, the fact that in fibroid tissue the arteries participated in the sclerosis, diminishing their calibre, was sufficient explanation of the slight tendency to hæmorrhage. Speaking of the scientific side of the paper, he remarked on the absence of tubercle bacilli in the cases narrated, and said that if all consolidations were characterised alike as of tubercular origin, it was a very odd sort of phthisis which could be cured by a simple operation like that to which the authors had drawn attention in the first case. The author's observations on the absence of bacilli in some cases of fibroid phthisis confirmed his own.—Dr. C. T. WILLIAMS, in reply, did not consider that operative treatment should be confined to cases associated with fibrosis and adherent pleura; there were mixed cases, and he would be sorry to shut out all other cases. As to the diagnosis of bronchiectasis, no doubt there was much uncertainty with total obstruction of a large bronchus, but he agreed with Sir Andrew Clark that there was some, but not always unsurmountable, difficulty in diagnosis. In his paper he had laid great stress on the presence of membranous shreds as of diagnostic value. Whether these were due to exudation or not he could not say, but as he believed they were not found in any other cases he regarded them as of much importance.—Mr. R. J. GODLEE, in reply, alluded to the question of hæmorrhage; in the neighbourhood of large bronchi he considered that hæmorrhage might be a very serious danger. In some cases of paracentesis in which the patient's mouth became full of blood he thought that a bronchial vessel must have been opened, and if such a patient were deeply anæsthetised the danger from suffocation would be very serious. In his experience of cases of pulmonary surgery he had always found

Digitized by Google

plugging sufficient to arrest any hæmorrhage. On the diagnosis of adhesions all he would say was that often when operating he had detected no adhesions, even after the asseveration to the contrary of some of the Brompton physicians. When soft adhesions were present the lung was easily pushed away from the parietes, and puncture was therefore difficult. In a case of what was regarded as loculated pleuritic effusion, it turned out, on operating, that but a few weak adhesions were present, and these being unavoidably broken down some fluid escaped into the general pleural cavity, with the development of septic pleurisy. The aspirator was certainly the best instrument to use in exploration; during the withdrawal of the cannula it was possible to ascertain whether a cavity had been traversed. In his paper he had referred only to cavities the result of bronchiectasis.

MEDICAL SOCIETY OF LONDON.

Amputation of Penis.—Alveolar Abscess with Thrombosis of Cavernous Sinus.

AN ordinary meeting of this Society was held on Monday last, Mr. R. Brudenell Carter, F.R.C.S., President, in the chair. An important ethico-physiological question arose in the discussion of the first paper.

Mr. F. BOWREMAN JESSETT read a paper on Amputation of the Penis by Pearce Gould's method, which will appear in full in an early number of THE LANCET.—The PRESIDENT considered that for certain individuals in the active sexual period it was proper to remove the testes in order to prevent the occurrence of repeated discomfort and chagrin from inability to satisfy the physiological desires.—Mr. PEARCE GOULD related another case of amputation of the penis by his own method, which occurred in his practice about two years ago. The patient was a man aged fifty-four, in whom the inguinal glands were involved; in the operation he removed also these affected glands. An ordinary glass syringe was a very convenient instrument to permit of micturition in the standing posture. He was not convinced of the necessity of removing the testicles in such cases, for in his opinion a chaste life was consistent with perfect health.—Mr. J. H. MORGAN spoke of the question of heredity in cancer, which varied according to the tissue in which the new growth occurred. He thought removal of the testes inexpedient, unless there were signs of disease of one or both organs, for mere castration caused considerable temporary depression in parts controlled by the sympathetic system.—Mr. W. PYE considered that mere castration was not an operation dangerous in itself. A perfectly chaste life was, he held, possible without deterioration of the general health; if the testicles were removed he should expect rather that important changes would occur in the body at large.—Mr. DAVIES-COLLEY referred to two cases of cancer of the body of the penis on which he had operated; he removed the organ at the root, and then opened the urethra in the perineum. This method was advocated by Thiersch in 1871, but Professor Humphry of Cambridge had performed a similar operation many years before this. He did not think that removal of the testes was called for.—Dr. W. M. ORD asked whether any trustworthy information existed as to the fatality of the operation that produced eunuchs in the East.—The PRESIDENT said that the operation was done at a very early age in the East, the patients being buried in sand to check the hæmorrhage and heal the wound; there was a certain percentage of deaths.

Mr. PEARCE GOULD read notes of a case of Alveolar Abscess causing death from thrombosis of the cavernous sinus. A widow, aged fifty-seven, was admitted into the Temperance Hospital with the mouth and teeth in a foul state; a sloughy opening was seen in the centre of the right cheek. An incision was made into the tissues over the jaw from the outside, where fluctuation was detected over the lower part of the masseter; the swelling of the face subsided a little after this, but the patient's general condition was very unsatisfactory. Six molar teeth were extracted on the right side on Feb. 22nd. A probe passed into the external wound detected bare bone; the trismus lessened, but there still remained continued fever and the mouth was very foul-smelling. Some œdema of the right temple had also appeared. Four days after the removal of the teeth, an abscess above the external angular process of the orbit and another in the posterior triangle of the neck were observed, but the external jugular was not thrombosed. The general state did not improve; the pulse was 126, small, and weak; the temperature 103·8°; respiration stertorous, and crops of herpes about the lips. The patient was very drowsy; there was great œdema of the orbit and chemosis, with some proptosis of the right eye and less of the left; the eyeball could be moved a little from side to side. The patient had some rigors on March 1st. The general asthenia increased, and on March 2nd the conjunctivæ were yellow and motions colourless. Death occurred in a state of coma. At the necropsy several globular abscesses were found in the lungs with very dense walls, and no signs of adjacent inflammation. The liver was fatty and enlarged; the kidneys healthy. There was necrosis of the outer part of the right side of the lower jaw; the temporal muscle was discoloured, but not actually purulent. Some lymph was detected along the basilar process of the occipital bone and sella turcica. The blood was more fluid than usual. The right cavernous sinus was greatly distended, and contained greyish-yellow broken-down pus and clots; the right ophthalmic vein was similarly affected, and the circular sinus with the superior petrosal on the right side. The inferior petrosal and lateral sinuses were healthy. The left cavernous sinus contained a clot, of which the inner part was yellow. The case appeared to be an example of a rare condition. The thrombosis had probably spread through the pterygoid veins on the right side to the cavernous sinus, and thence to the left side by the circular sinus. Sir William Bowman's case was mentioned in which there was pulsation in the orbit, which led to ligature of the common carotid on the idea of aneurysm.—Mr. B. CARTER referred to two cases of orbital cellulitis in which there was proptosis; both recovered.—Dr. SIDNEY COUPLAND had met with thrombosis of the cavernous sinus after death, when it had never been expected during life. In Mr. Gould's case we had a parallel to thrombosis of the lateral sinus occurring after ear disease. He related a case of basic meningitis in which there was total ophthalmoplegia and loss of sensation in the ocular tissues; at the necropsy there was ancient plugging of both cavernous sinuses. During life there were no signs of papillitis; there was no "choked disc," showing that V. Graefe's explanation was incorrect, as had now been generally accepted.—Mr. DAVIES-COLLEY related three cases of thrombosis of the cavernous sinus occurring in cases of malignant facial carbuncle.—Mr. ALLINGHAM, jun., spoke of the case of a girl, aged twenty-one, who died with thrombosis of the facial vein and cavernous thrombosis; there was extreme chlorosis.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

On Suction of Sewer Gases into Service-pipes conveying Drinking-water—a fertile causation of Enteric Fever.

A MEETING of this Society was held on Friday, Jan. 15th, Dr. Corfield, President, in the chair.

The objects to which the author of the above paper, Dr. HORACE SWETE, alluded, was to show an insidious danger that existed where a vacuum was formed by water-pipes being suddenly turned off from the main, and the means he had devised to prevent such an occurrence. He first pointed out the danger attending the intermittent water-supply, and very often also the constant service supply, as various occasions arise for shutting off portions of the water-supply for making repairs, flushing, &c.; it is when this happens that a vacuum is formed and sewer gases admitted into the water-pipes. This was illustrated, first, in Dr. Blaxall's report to the Local Government Board of enteric fever occurring at Sherborne; secondly, in that notable case of typhoid fever at Caius College, Cambridge, where Dr. Buchanan in a most masterly way discovered the source of sewer gas in the one watercloset which was attached to the room of one of the Fellows, in which during his absence the dry weather caused the small syphon of the weeping pipe to dry up, and gases freely came from the town sewers, and were sucked into the pipes supplying the students with water. Dr. Swete then referred to his own personal knowledge, how he found coal-gas at Droitwich in the drinking-water sucked in from an adjoining gas main; and again at Kidderminster, the water-supply falling short, the main was turned off daily for several hours, the cause of the outbreak here being not in the well water, but in that which passed through the pipes, which, being constantly milky when drawn, showed that air—viz., sewer gas—had

Digitized by Google

found its way by suction into the vacuum formed by the water having been turned off. He then went on to point out the means of preventing this danger, and came to the conclusion that the only true protection would be to admit air into the highest point of house service pipes whenever the water was turned off, thus effectively to prevent suction either by syphon action or by the formation of a vacuum in the service-pipes. To effect this he constructed a dome-shaped valve, inside which a float surmounted by an elastic disc presses against a metallic diaphragm; above the diaphragm are holes to admit air, so that when the water falls the float falls with it, and air is admitted; when the water is again turned on, the float rises and seals the valve; the greater the pressure the more closely the valve is sealed. The objections that have been raised against these valves are: 1. It is a sanitary fad, and there are plenty of others in the market. There are certainly some traps, and also an automatic valve, which entirely failed at Caius College, Cambridge. 2. Why not simply bore a hole in the top of the service-pipe and so admit air. Truly, such a hole will admit air, but what a splendid fountain would be made with a head, say, of 250 feet of water! 3. What is the necessity of such valves when we have separate cisterns for the waterclosets? These often fail, as was the case in the typhoid outbreak at Kidderminster. 4. The fear that, unless care is taken to place the valve where foul air cannot touch it, it would not be of much use. To this objection the author stated that it was not intended to place the valve under any watercloset, but to keep it at the highest point outside any such place; even were it placed inside, the air could only act on a very small film of water and without any pressure; whereas in suction, air, conveying with it organic matter, passes through a considerable quantity of water in the pipes, and all organic impurity is washed from the air-bubbles into the air.

NORFOLK AND NORWICH MEDICO-CHIRURGICAL SOCIETY.

Suture of the Ulnar Nerve.—At the March meeting of the Norfolk and Norwich Medico-Chirurgical Society, Dr. MICHAEL BEVERLEY showed a patient whose ulnar nerve he had sutured in November last. H. G. ——, aged sixteen, received a severe wound above the left wrist by the bursting of a ginger-beer bottle on August 19th, 1885. When first seen by Dr. Beverley, ten weeks afterwards, the cicatrix was extremely painful, especially if the fingers were extended; there was complete loss of sensation in the little finger and half of the ring finger, both of which drooped, and wasting of the muscles on the outer side of the hand, where the skin was cold and clammy. On November 12th (twelve weeks after the injury) Dr. Beverley made an incision along the course of the ulnar nerve one inch above and below the cicatrix; it was found to be severed; the proximal end was bulbous, and attached by its sheath to the tendon of the flexor carpi ulnaris, which was itself lacerated by the original injury; hence the pain which was produced by any movement which extended this tendon, and thus stretched the sheath by which it was connected to the upper segment of the divided nerve. The distal end of the nerve was retracted and separated from the proximal by nearly half an inch. A fresh section was made through the ends of the divided nerve, and they were brought into accurate opposition by two fine chromicised catgut sutures. There was very little tension when the hand was semi-flexed, in which position it was retained by an angular metal splint. The operation was performed under carbolic spray and with strict antiseptic precautions. The wound healed by first intention. On the third day after the operation there was slight tingling in the little finger, on the sixth day slight sensation to the touch, and on the ninth day decidedly returning sensation. On the fourteenth day the hand and arm were thoroughly examined, and it was found that sensation was partially recovered in all the parts from which it had been absent before the operation. A fortnight later the splint was removed, and the patient was directed to use his hand gently; there was a very decided return of sensation, and the drooping fingers could be slightly raised. The subsequent progress of the case has been very satisfactory. He can now (March 1st) move the fingers extremely well. Sensation has completely returned, and the hand is of nearly as much use as it was before the accident. In his comments on the case, Dr. Beverley referred to instances of successful nerve-suturing recorded by Langenbeck, Esmarch, Virchow, Hulke, Heath, and Langton.

Reviews and Notices of Books.

Handbook of Geographical and Historical Pathology. By Dr. AUGUST HIRSCH. Vol. 2: Chronic, Infective, Toxic, Parasitic, Septic, and Constitutional Diseases. Translated from the Second German Edition by CHARLES CREIGHTON, M.D. London: The New Sydenham Society. 1885.

THE subjects contained in this volume of Professor Hirsch's classical treatise include many diseases of great interest from the historical and geographical standpoint. Leprosy, syphilis, goitre, puerperal fever, and scurvy are amongst the number which are subjected to the penetrating analysis of the learned author, whose researches have done so much to complete our knowledge of disease. The scope of the volume will, however, be best gathered by a summary of the chapters, as follows:—*Chronic Infective Diseases:* (1) Leprosy; (2) Syphilis; (3) Yaws, Button Scurvy, and Verruga Peruviana; (4) Endemic Goitre and Cretinism. *Toxic Diseases:* (5) Ergotism; (6) Pellagra and allied diseases; (7) Milk-sickness and the Trembles; (8) Endemic Colic. *Parasitic Diseases:* (9) Animal Parasites; (10) Parasitic Fungi. *Infective Traumatic Diseases:* (11) Erysipelas; (12) Puerperal Fever; (13) Hospital Gangrene. *Chronic Disorders of Nutrition:* (14) Chlorosis and Anæmia; (15) Scurvy; (16) Beri-beri; (17) Scrofula; (18) Diabetes; (19) Gout. Although under the term "leprosy" there has no doubt been included a great variety of skin affections, which add to the difficulties of the historian to assign a proper value to old chronicles, there appears to be sufficient evidence of its occurrence in Egypt, India, and Japan in very remote periods. Professor Hirsch thinks that the biblical term "sâraat" (Leviticus xiii.) probably includes leprosy as well as other affections, as psoriasis, scabies, eczema, and perhaps also syphilis. The same confusion explains, he thinks, the vast number of leper houses in Europe in the middle ages, for although true leprosy was probably then endemic, it is hardly conceivable that it should have prevailed so largely, especially as we have in syphilis a far more probable explanation of the vast increase in cutaneous disease which coincided with the Crusades. At the present day endemic leprosy is very circumscribed in Europe; it occurs in parts of Spain and Portugal, in Italy, on the Gulf of Genoa and the Adriatic, in Sicily (where it has been on the increase), in Greece, and especially in Crete; whilst it has died out in Roumania, Hungary, and Southern Russia, and has gradually decreased in Sweden, but prevails, as is well known, in Norway and in Iceland. Its distribution in other parts of the globe is too diffuse to summarise, but there is ample evidence that climatic and soil conditions are not the sole factors favouring it. The influence of a diet of fish, especially of putrid fish, which has been so staunchly maintained by Hutchinson, is discussed by Hirsch, who concludes that the theory is one-sided and untenable. The proofs in favour of a specific infective virus which have accumulated within the past ten years give all such speculations as to the operation of dietetic, hygienic, and climatic influences a subsidiary importance. The question of the contagiousness of leprosy is met by Hirsch with many facts showing how little there is to support it, whilst the transmission of an inherited predisposition is thoroughly established. That the disease can be acquired by Europeans who reside in leprous localities abroad is also established, and it is remarkable that a few cases have so arisen in "regions where leprosy as an endemic had been extinct for centuries." As with leprosy, so with syphilis; ancient writings afford evidence enough of its existence in the earliest times, but there is no question that about the end of the fifteenth century a great epidemic overran Europe. Some curious facts respecting

Digitized by Google

immunity from syphilis are to be found in the section dealing with its present geographical distribution. Thus it is comparatively rare among the Hottentots, and the pure African negro seems quite exempt; whilst in Madagascar and the adjoining island, Ste. Marie, the Malagasys enjoy an immunity which is not shared by the Hovas. Syphilis, indeed, has been spread over the globe by the advance of colonisation, and there are regions where it has not yet penetrated. Yaws or frambœsia, at one time thought to be syphilitic, is a specific highly contagious disorder of strictly tropical distribution; allied to it is the button scurvy of the south of Ireland and the Peruvian wart (verruga). Endemic goitre and cretinism are very fully dealt with; but the result of Professor Hirsch's inquiries tends to weaken the prevalent notion that these diseases depend upon a special character of soil or the impregnation of water by magnesia; and after refuting the various theories proffered in this connexion, he inclines to the view that there must be a specific morbid poison at the root of these closely related conditions. We must be contented with a mere reference to the articles on Ergotism, Pellagra, and Acrodynia—an interesting group of toxic affections attributable to the consumption of diseased grain. "Endemic colic" is proved to be nothing else than lead colic. The various parasitic diseases receive full notice, and their geographical distribution, known to be so markedly defined, is admirably sketched. Particularly may be cited the articles upon Trichina spiralis, Anchylostoma duodenale, Filaria sanguinis hominis, and the Guinea-worm. Since the publication of this volume a great deal has been added to our knowledge of anchylostoma. Of the remaining articles those on Puerperal Fever abound in facts of its infective nature; but the question of the various morbid conditions undoubtedly grouped under this head is not considered. The articles on Scurvy and Beri-beri are also full of information, and of much interest. But, in truth, the whole work shows the master's hand; and we cannot be too grateful to the New Sydenham Society for presenting us with a translation of it, and especially for having assigned the labour of translation to so excellent a scholar as Dr. Creighton. Professor Hirsch's work is one of those which will be of permanent value, and one which no writer on medicine should fail to consult. It is thus of great advantage to have it rendered into English in so worthy a manner.

The Rotifera or Wheel Animalcules. By C. T. HUDSON, LL.D.Cantab., assisted by P. H. GOSSE, F.R.S. Parts I, and II. London: Longmans, Green, and Co.

A MANUAL of the Rotifera has long been a desideratum in our language, and we cannot suggest the names of any naturalists by whom an exhaustive description of this interesting group could be better given than by Messrs. Gosse and Hudson. Mr. Gosse's writings on this very subject date back, if we mistake not, some thirty years, and Mr. Hudson is well known to have devoted much attention to it. Part I. contains an introduction in which the anatomy of a typical species, the Brachionus rubens, is given, with numerous figures of the several parts of the body. The second chapter contains the history of the literature concerning the rotifera, from which it appears that the first vague description of a rotiferon was given by Mr. John Harris, the rector of Winchelsea, nearly 200 years ago. In 1703 Leeuwenhoek published an account of some animalcules in the Philosophical Transactions, which the authors of the present work consider can be identified with Limnias ceratophylli. Eichhorn, after whom one species, the Stephanoceros eichornii, has been named, published a little book in 1781, in which he gives figures and descriptions of about a dozen rotifera that can be identified. Since that time about twelve or fifteen observers have published essays of importance, and their results will, we have no doubt, be gathered up in the work before us. The third and fourth chapters deal with the classification and the haunts and habits of the rotifera. There are five plates, which are really beautifully executed. The figures are so large that there is no confusion in the outlines of the several organs and the parts are drawn with great precision. The genera—if that word is permissible—which are illustrated are the Floscularia, Stephanoceros, and Melicerta. Part II. of this charmingly got up book contains an account of the Floscullariadæ and of a part of the Melicertadæ. It is illustrated by seven double plates and one single one. The descriptions of the animals are distinct and clear, and the drawings leave nothing to be desired. We can recommend the work to all lovers of nature, and to any of the members of our profession who possess a microscope, and who can find time in the evening to examine the beautiful animals which a chance dip in a wayside pool may present to their notice.

Psychiatry. By T. MEYNERT. Translated by R. SACHS. Part I. New York and London: G. P. Putnam's Sons. 1885.

THIS is an American edition of Professor Meynert's Psychiatry, and will be welcomed by English readers who are unable to translate the German text. The translator acknowledges his shortcomings, but craves the indulgence of his readers. We must confess that he has not presented a readable book to the medical public, but we own that difficulties of translating a German work on the anatomy, physiology, and chemistry of the brain are great, though hardly insurmountable. The structure and architecture of the brain, the minute anatomy of the brain, anatomical corollaries and physiology of cerebral architecture, the nutrition of the brain, and an appendix on the mechanism of expression, are the chief headings of the work before us.

We cannot enter into a review of Meynert's anatomy, and must confine ourselves to a limited allowance of his physiology. "Sensitiveness is the only specific property of brain cells," we are told, and, viewed in the light of one's own interpretation, no doubt this statement may be regarded as true. Nerve cells are the most irritable and we suppose the most sensitive structures evolved from the primordial ovum, but they "discharge" energy in the manifestation of their only specific property. "In the fore-brain sensitiveness is converted into actual sensation." The meaning of this statement is not altogether clear. Actual sensation is no doubt impossible in the absence of the fore-brain—i.e., the cerebral cortex, It is not right to speak of unconscious sensations; we cannot have a sensation merely as the result of the action of sensory end organs, or the paths leading from and to centres situate below the cerebral cortex. When a frog deprived of his cerebral hemispheres survives, he does so by the aid of sensory impressions, which must not be regarded as sensations. Except for convenience of language, surely such a distinction of sensory impressions is not essential, and certainly not scientific. Viewed in the light of evolution, it is only those recently acquired functions that are perfectly conscious; repetition of functions leads to their unconscious performance. Consciousness is purely a question of degree. Are we sure that the brainless frog does not feel consciously the impressions that give rise to reflex actions? But the subject is endless. Meynert says that the volitional acts are nothing more than the perception or memory of the sensations of innervation. We cannot accept such a definition of a volitional act; nor are we certain that such acts differ much from so-called reflex actions. The deliberation that we presume must take place in the sensori-motor centres may be greater when volitional acts are concerned, but can we know whether a certain amount of deliberation does not occur in the simplest action?

THE LANCET.

LONDON: SATURDAY, MARCH 27, 1886.

THE striking and impressive ceremonial of Wednesday last may at first sight appear to have been more than commensurate with either the magnitude or public importance of the work it inaugurated. A little consideration will, however, show that the occasion was one which was well worthy the gratifying recognition which it received at the hands of Royalty. The readiness with which Her Majesty the QUEEN consented, or rather, if report speak truly, expressly desired, to take part in the proceedings of the day, was doubtless in large measure due to the personal regard which our Sovereign and the members of her family entertain for those eminent and sagacious counsellors of whom the justly venerated President of the College of Physicians stands foremost. Her Majesty gave expression to this feeling in her own well-chosen language, and the members of our profession will receive with satisfaction her graceful allusion to the physician who has served his QUEEN and his profession so well.

Although such personal considerations may have had some influence in ensuring the presence of Royalty upon this occasion, the profession must feel that the honour was conferred upon it as a body as much as upon the two Colleges directly concerned. It was evidence of the keen interest which Her Majesty takes in the labours of medical men, as well as of her appreciation of all they are doing for the good of humanity. In the course of her long reign she has witnessed many improvements in the social and material condition of her people which have been due to the increased knowledge and practical application of the principles of medicine. The Victorian era will stand out in history as the period in which science made its greatest advances; and what is true of science in general is quite as true of medical science, whereby so much has been done to solve the problems of disease, to mitigate its ravages, and to check its spread. It has been the era of sanitation — of disease prevention even more than of its cure. Within a generation how great and incalculable have been the gains derived from the wider observance of the laws of public and personal hygiene! The men who have done so much to diffuse a knowledge of the laws of health constitute that profession whose office it is to minister to the sick, with the result that there are some diseases which have almost been banished from the nosology, whilst there are others which are in a fair way to extinction. The world at large is apt to forget how much has been added to the sum of human happiness by such methods as directly arise from the knowledge of the causes of disease and of the conditions that promote health; and we are disposed to fear that as a rule the medical profession receive but little gratitude for the share they have taken in this work. Therefore we gladly and gratefully acknowledge this expression of Her Majesty's goodwill, for the welfare of her subjects has ever been her concern, and her discrimination of the part played by medicine in promoting that welfare is just and discerning.

The ceremony of Wednesday had a further significance. It was concerned more directly with the cause of medical education in this country. It is well known how this has improved during the past decade, for every advance in medical science is reflected in the student's curriculum. The great licensing bodies have the responsibility of prescribing and regulating this curriculum. Upon them depend all changes which, by improving and widening it, raise the character of medical education, and proportionately strengthen the resources of the medical art. As regards the two Royal Colleges, they have hitherto been separated in this important work, kept apart doubtless by the traditions of ancient rivalry. We live in a more liberal age; and just as in its higher functions the College of Physicians has got rid of much of its exclusiveness, so in its more important duty of granting licences to practise the barriers between the Colleges have been swept away. The co-operation of the Colleges in this work has its outward and visible sign in the building in the Savoy, which in future will form the connecting link between Pall-mall and Lincoln's-inn-fields. The result of this union will act in a most salutary manner upon the course of medical study, and will probably have still wider issues. For it must have occurred to many who witnessed the great gathering of physicians and surgeons that the stone laid by Her Majesty was not merely the foundation of an Examination Hall, but was the first step towards the realisation of a real University for London. All the elements of a medical faculty which might form the nucleus of such a University were present; the two Colleges are engaged in considering how best to solve the problem of giving to London students facilities for taking medical degrees; and it seems but to need one slight advance in their natural evolution to supply this want. Since all the teaching bodies are represented in the Colleges, the assumption by the latter of a control over teaching more direct than the formulation of a code of examinations should not be difficult or unreasonable. We may well regard the Royal recognition of the work done by the Colleges in the cause of medical education hitherto as an encouragement to them to pursue their combined efforts to the benefit of the profession, and through it of the community at large.

As to the ceremony itself, it could not have passed off with greater success; and those who have done so much in assiduous preparation for it as the Presidents (Sir W. JENNER and Mr. SAVORY), Dr. BIRKETT, Dr. OGLE, Mr. WOOD, Mr. H. POWER, Sir H. PITMAN, Dr. DUCKWORTH (Chairman of the Building Committee), Mr. TRIMMER, and Mr. SALTER (the architect of the Examination Hall)—to name only a few—are much to be congratulated. To these must be added the name of Professor JOHN MARSHALL, whose influence in the College of Surgeons has had so much to do in bringing about the union of the two Royal Colleges. Everything aided in making it successful. The bright and balmy day of early spring was all that could be desired in point of weather. The vast gathering of medical men was thoroughly representative of every branch of the profession and of every department of the two Colleges. The warmth with which they greeted Her Majesty, the Heir-Apparent, and those other members of the Royal Family who graced the proceedings by their presence, testified to the manner in which the honour bestowed on the profession was appreciated.

Digitized by Google

Her Majesty, who appeared in excellent health, performed the duties of the day with a genial cordiality which proved how thoroughly she entered into the spirit of the occasion, which was further shown in the reply she made to the address read by Mr. SAVORY. On behalf of the medical profession, we may echo the sentiments expressed by Her Majesty, and confidently trust that the undertaking commenced that day "may largely contribute to the further advancement of medical and surgical education." The day will be a memorable one in the annals of our profession, and it will be our own fault if the work so brilliantly inaugurated be not pursued to a great and worthy fulfilment.

ON the 16th inst. the Rivers Pollution Bill was rejected by the House of Commons, and the country has now simply to depend upon the legislation of 1876 as the only means for controlling the pollution of rivers and streams. This Act has been found to be altogether inadequate to prevent a growing nuisance and a growing danger to health. It was anticipated that it would control pollution by sewage and pollution resulting from manufacturing processes, but it may be said without exaggeration to have failed generally to prevent either the one or the other. This failure is due chiefly to the absence of any power to move local authorities, who can alone take proceedings under the Act. The local authorities upon whom this duty devolves are the sanitary authorities through whose districts or by whose districts a stream passes, and, as Sir CHARLES RUSSELL recently pointed out, it is these authorities who are themselves the chief offenders. To remedy this obvious defect, the Bill of this session proposed to confer on private individuals who were aggrieved by the pollution the right to institute proceedings at the cost of an authority which neglected themselves to take the initiative. This right is obviously so much open to abuse that it did not commend itself to the good sense of the House of Commons, but the fact remains that local sanitary authorities cannot be trusted to carry out the duty, and further machinery is required to prevent the Act from being a dead letter.

The real opposition to the Bill, however, probably came from those who feared interference with the manufacturing industries of the country. Under the Act of 1876 no authority can institute proceedings concerning pollution from manufacturing processes without the consent of the Local Government Board; but in the Bill of the present session it was proposed to confer the power upon any authority or person interested to take proceedings in a County Court without such consent. The Bill has now been rejected, but it is sure to make its appearance in a modified form during another session. There ought to be no difficulty in the way of amending it without injury to its usefulness, and so as to make it acceptable to a majority of the members of both legislative bodies; but it is perfectly obvious some course must be adopted which will neither leave the institution of proceedings in the hands of authorities who are indisposed to move, nor confer this right upon private individuals to protect their own interests at the public expense. There is indeed necessity for the creation of some other authority, upon whom should devolve the duty of investigating complaints and of taking proceedings where these are upon inquiry shown to be well founded. The existence of such an authority would render unnecessary the adoption by Parliament of definite standards of impurity, such as those incorporated in the Bill. Chemistry must doubtless play an important part in determining any decisions which are come to in any case under consideration; but it is at least open to doubt whether it is desirable for a standard to be incorporated in any Act which is based upon the estimation of the amount of carbon and nitrogen in any liquid. Mr. CHAMBERLAIN'S belief in local government leads him to argue that the main remedy is to be found in improved local bodies for dealing with this and other questions; but we fear it is doubtful if this much-desired change, even supposing it were brought about, would enable any effectual action to be taken. The pollution which results from the negligence of one of these bodies constitutes so great a danger to other districts that the subject can only be dealt with seriously when it is regarded as a matter of national rather than local concern.

The promoters of the Bill will evidently have sufficient work before them to create an interest in the question sufficient to overcome the opposition which they will meet. They have not lessened their difficulties by omitting to deal separately with pollution due to sewage and pollution caused by manufactures. The danger to health of these two conditions is different, and there is a likelihood that they will succeed earlier with the former than with the latter. Although they have met with a temporary defeat, their labours have not been altogether thrown away, and they will doubtless at a later date bring forward a measure which will deserve and meet with a better fate than that which attended the rejected Bill.

DR. ROBERT F. WEIR recently read a paper before the Medical Society of the State of New York, in which he related seven cases in which he had treated chronic effusions in the knee-joint by antiseptic irrigation. As Dr. WEIR is careful to point out, this treatment was introduced by SCHEDE in 1875, and since then has been practised by many surgeons, especially in Germany; but, judging from the teaching of English surgical text-books and periodical literature, it has not won its way in this country, and Dr. WEIR says the same for America. It may therefore be well to draw attention to this plan of treating an obstinate and serious affection. The cases for which it is suggested are those of subacute and chronic serous synovitis, which resist the usual methods of treatment — rest, counter-irritation, absorbents, and pressure. It is not proposed that all cases of synovitis should be treated in this manner, but that a careful selection should be made. The treatment consists in tapping the joint with a trocar about the size generally used for hydrocele, and then, when all the fluid has escaped through the tube, a quantity of carbolic acid solution (5 per cent.) is injected through the cannula, and allowed to flow out. This is repeated until the fluid returns from the joint quite clear and free from flakes, and then the cannula is withdrawn, and the puncture closed by a pledget of boric lint, over which an abundant antiseptic dressing is fixed. In performing this simple operation it is well not to admit air to the joint; this can usually be prevented by carefully adjusting the pressure of the hand; an antiseptic spray may be employed to play over the cannula

Digitized by Google

as an additional safeguard. After the operation the limb should be fixed upon a back splint or in a plaster-of-Paris case. As a rule the pain and reaction afterwards are slight, and quickly subside, and all dressings can be removed in the second week, and the patient gradually bring his joint into use again. The synovial membrane can usually be felt to be markedly thickened, but the joint is otherwise sound. Dr. WEIR reports seven cases which he had treated in this way, and refers to thirty-two others which he has found recorded by other surgeons. VOLKMANN is stated to have treated hundreds of cases by this method, without a serious complication in any case. Such a sweeping and vague statement is, however, of little scientific value, and will certainly fail to recommend the method to judicious surgeons.

Putting aside such statements as this of VOLKMANN'S, the evidence before us certainly warrants a careful trial of this method in suitable cases. Our resources in such cases have not hitherto been great. Where rest, counter-irritation, compression, and the use of absorbents have all failed, three courses have been chiefly practised—aspiration, injection, and drainage. Aspiration is sometimes successful, but is by no means reliable; often it fails to remove the whole secretion, and, whether from this cause or not, reaccumulation of the fluid only too commonly follows. Injection of the joint with iodine—as for the radical cure of hydrocele—has long been advocated, but is not now largely used in this country; experience has shown that it is not free from risk, and that suppuration may ensue. Antiseptic drainage of the joint, on the other hand, has been attended with good results, but it must be regarded as a severe measure. Should the precautions taken fail in their aim, a violent suppurative inflammation may be lighted up, imperilling the joint, the limb, and the patient's life itself. Compared with it, antiseptic irrigation of the joint is certainly a milder measure, is attended with less danger, does not require such complete acquaintance with the details of aseptic surgery, and when successful restores the patient to activity in a much shorter time than antiseptic drainage. On many grounds it commends itself, and if further experience corroborates the opinions already expressed upon it we shall have acquired a very useful addition to our means of dealing with a very troublesome affection.

THERE is a distinction to be drawn between suicide *from* fear and suicide *for* fear. There is not probably any large proportion of cases in which self-murder is committed for fear of evil. The fear of detection in crime very seldom induces a wrong-doer to kill himself. The chances of concealment generally appear to outnumber those of discovery. When once suspicion threatens to ripen into conviction the outlook darkens and the probability of suicide increases, but still the blunted moral sense seeks refuge in hope, and few criminals incline to self-murder for fear of conviction. After they have been convicted, suicide instead of death by the hand of the executioner is a matter of sentiment, and the traditional belief or impression that self-murder will entail evil after death is generally sufficient to determine the condemned to die on the scaffold rather than by their own hands. Suicide for fear of ills less than the death-penalty are probably even fewer. There is generally as much courage latent in the mind [illegible] will enable a man to face adverse fortune, however formidable it may seem. The very aggressiveness of the evil rouses a spirit of opposition. As a rule, few men, and scarcely any women, are craven enough to seek death as a way of avoiding adversity, or even extreme poverty, if it be not disgraceful. The suicides of women, fearful of shame, are, with rare exceptions, the indirect effect of mind-weakening or prolonged agony from fear, rather than cases of self-murder prompted by fear acting directly.

This is the distinction we are desirous of drawing between the two forms of self-slaughter: on the one hand, suicide because the offender is afraid of something, and prefers death to it; on the other hand, suicide which is the result of demoralisation or depreciation of the strength of self-control by the accumulation and wearing pressure of a terror which is not so much a particular fear as a general fearfulness. Even those who are least well acquainted with the clinical characteristics of mental disease are aware that *suspicion* is one of the salient symptoms of those varieties of mind derangement which in their development produce suicidal or homicidal propensities. There is at first a vague feeling of being in peril of some sort, a sense of impending evil; then comes the idea of being too much noticed by others; presently the sufferer feels that he or she is watched; and at length there comes the horror of being pursued or haunted by physical, or it may be spiritual, beings. In its making this madness has fearfulness rather than fear for a principal factor; and in cases of suicide occurring without previous symptoms of insanity there is, generally speaking, an inordinately rapid and, as it were, premature development of the same terror which in ordinary and more typical cases of mental disease culminating in suicide or a suicidal tendency, undermines the judgment or overpowers the will more slowly. Suicide *from* fear is familiar enough. It is commonly preceded by secrecy or shyness, with a fitful, moody state of mind, and an aspect of distrust or concealment. There is not unfrequently a tendency to seek relief in religious exercises, in prayer, Bible-reading, or the services of a church or society, although the subject of this impending trouble is seldom more than a quiet member, with retiring manners and an almost preternatural docility. When a man or woman who has been at least moderately, perhaps somewhat excessively, demonstrative and self-assertive, suddenly becomes subdued, retiring, or even diffident; when there is a tendency to repeat the smaller actions of common life—such, e.g., as shutting doors and drawers, turning off gas-taps, and the like,—as though to make assurance doubly sure; when there are noticeable sly glances or an air of fearfulness,—that person, however rational and even exceptionally calm and forbearing may be the general demeanour, is in peril of passing into such a state of mind as may readily express itself in suicide. We often hear of resignation, and great sorrows bravely borne in secret; there is far more of danger in the practice of these virtues than in the loudest and most aggressive complainings. Because the destructive operation of persistent fearfulness is carried on in secret and elaborately disguised by the victim of its evil influence, cases of this suicidal tendency are too commonly overlooked, with the result that deaths by self-murder from fear are very numerous; although in the great majority of

Digitized by Google

instances the morbid mental state is one which, if promptly and wisely treated, will prove susceptible of remedy. "Am I my brother's keeper?" is too conventional an expression of the prevailing sentiment in social life. If only there were more real friendliness in families and among men and women generally, there would be fewer suicides, not so much because the troubles of life would be relieved, as because that morbid sense of apprehension which does its most deadly work in secret would be checked in its development.

As practitioners of the art of healing, our duty is not limited to the feeling of pulses and the looking at tongues. If we would do our very utmost for those with whom we come in contact, it should be our aim to engender in the minds of our patients such a feeling of confidence in our honour and wisdom, that, without prying into their secret affairs, there may grow up in their minds a consciousness that there is always counsel and help to be had for the seeking. A mind struggling with the growing sense of fear will not always need to unbosom itself to secure relief. We all know how, in crossing a narrow plank bridge, the consciousness that there is a handrail will often give the pedestrian steadiness without the need to grip it. If he should require to grasp it, he knows it is there, and can find it. So is it with moral aid and guidance; the fact that it can be obtained when needed is in itself a source of strength and comfort, without actually confiding the trouble in words to a stranger. In this most terrible ordeal of *fear* the mind will often pass unscathed through the fire if only it can feel that there exists a trusty friend and protector at hand, and suicide from fear may thus be avoided. It is the noble and happy mission of the medical adviser—not the specialist, but the general practitioner—to minister thus lovingly to minds diseased, and there is no more worthy aim than to qualify oneself for the discharge of this most important function.

THE meeting of the Council of the Hospital Sunday Fund at the Mansion House on Tuesday was a very satisfactory one. It was called to consider certain suggestions by Dr. WAKLEY for increasing the public interest in the Fund and developing the collection to proportions more commensurate with the needs and merits of the hospitals of the metropolis. In the unavoidable absence of Dr. WAKLEY, these suggestions were introduced to the notice of the meeting by Mr. HENRY C. BURDETT. They are briefly as follows. 1. That a list of the wealthier workers and landowners in London who are non-resident be prepared in anticipation of Hospital Sunday. 2. That a week before the date of Hospital Sunday a letter by the Lord Mayor be sent to each of the non-residents. 3. That arrangements be made for a public meeting to be held in different parts of London on each day of the week preceding Hospital Sunday. 4. That the committee of every hospital in London shall be urged to prepare statements showing the work which it accomplishes: (*a*) for the whole of London; (*b*) for people outside of London; (*c*) especially for the inhabitants of the district in which it is situated; and that the hospitals in each district be asked to combine to canvass ministers of religion and the influential residents in the district, with a view to excite local as apart from metropolitan interest in the hospitals, to promote attendance at the public meetings and increased contributions to the Fund. 5. Two special supplements of THE LANCET will be published, one in the week preceding and another in the week following the collection, the first giving a description of the claims and needs of the hospitals, the second a record of special sermons on Hospital Sunday. 6. The hospitals or portions of hospitals might be usefully thrown open to the public under certain regulations, and an attempt might be made to induce the wealthy to visit these institutions, while special facilities might be afforded to the clergy to make themselves personally acquainted with the working and management of one or more of the hospitals.

The meeting of the Council was one of the largest and most representative which has been held. The suggestions, though not discussed in detail, were very cordially received, and in the end, on the motion of Sir SYDNEY WATERLOW, seconded by Sir EDMUND CURRIE, were referred for consideration to a Special Committee. This Committee was empowered to spend on its investigations not more than £150. It is the pride of the Council of the Hospital Sunday Fund to be very economical in its methods, and to spend all the money it gets, save something like 3 per cent., on the sick poor. Sir SYDNEY WATERLOW therefore was quite right in stipulating that the Committee should not exceed a certain limited amount without further appeal to the Council. But, obviously, statistical and clerical work and the holding of public meetings cannot be carried out without some outlay. This will be well justified if it brings a few more thousands into the coffers of the Fund. Sir EDMUND CURRIE in his speech showed that while the hospitals were very grateful for what was done, the amount raised was quite inadequate to the want, and that in some cases small contributions to the Fund were used as excuses for not giving proper annual subscriptions. Mr. BURDETT replied to the latter objection pretty effectually by showing that in places where Hospital Sunday was established subscriptions increased rather than diminished, and that the sermons of Hospital Sunday were a great means of diffusing knowledge of the work and claims of hospitals. The public will look forward to the work of the Committee with interest. There must be thousands of gentlemen who find their work and wealth in London who leave the town from Saturday to Monday, and so miss the powerful appeal which is made to the residents in London. Such gentlemen will not be ungrateful to the Lord Mayor for reminding them of the claims of those institutions, in which their servants and poorer neighbours find the highest medical and nursing skill, and their medical attendants the education which makes them so efficient in those emergencies of disease which arise even in the country.

A SPECIAL meeting of the Royal Medical and Chirurgical Society will be held on Tuesday, the 30th inst., at 8.30 P.M., when the subject of Supra-pubic Lithotomy will be discussed. Papers will be read by Mr. Barwell, Mr. Walter Rivington, and Mr. W. H. A. Jacobson, and an interesting debate may be anticipated.

NEXT May a Medical Congress under the auspices of the Scientific Athenæum of Valencia is to meet in that city for the "calm and dispassionate discussion" of Dr. Ferrán's anti-cholera inoculations, with the hope of arriving at an unbiased view on that much-debated subject.

Annotations.

"Ne quid nimis."

SIR WILLIAM JENNER, BART., K.C.B.

AT the present time it may be interesting to briefly recall the circumstances which led to the appointment of Sir William Jenner as Physician to the Queen, and many of our readers will still remember the accident by which the talented and respected physician who, had he lived, would in all human probability have obtained the coveted post—we allude to the late Dr. Baly—lost his life. The late Dr. Parkes had been spoken of as the probable successor of Sir James Clark, but his failing health rendered such an appointment undesirable. Sir James had long had the intention of introducing Dr. Baly to Her Majesty, and of recommending him as successor to himself in the post of Physician in Ordinary to the Queen; and there is little doubt that this design would have been carried out had it not been for the accident resulting in Dr. Baly's death, which occurred on the South-Western Railway whilst he was travelling to Guildford to see a child suffering from diphtheria. The carriage in which Dr. Baly was seated, asleep, with his handkerchief over his face, was turned completely over; the door near him flew open, and he was tilted out, receiving in the fall injuries which killed him immediately. Although there were other passengers in the same compartment, they escaped with slight or no injury, and it was thought at the time that Dr. Baly came by his death owing to his being asleep when the accident occurred, and consequently unable to make any effort for his safety. It is a curious coincidence that the local practitioner under whose care the child at Guildford was had mentioned to its parents the names of three physicians, Dr. Baly, Dr. Jenner, and another whose name at this moment has escaped our memory, as being suitable to be summoned in consultation, Dr. Jenner going to see the little patient the next day, when he also identified the body of Dr. Baly. Some time afterwards Sir James Clark introduced Sir William to the Queen, and his appointment was soon gazetted as Physician in Ordinary to Her Majesty, of which onerous and responsible post he has now discharged the duties and enjoyed the honours for over twenty-five years. It is worthy of mention that Her Majesty has during her lifetime been under the care of only two physicians—Sir James Clark during, roughly speaking, the first forty years, and Sir William Jenner during the remainder. The Queen is, we understand, a model patient, and her confidence in her medical attendant, when once vouchsafed, is implicit. In this respect, as in many other aspects of her life, she affords an exemple which many of those over whom she reigns could follow with advantage. For five consecutive years Sir William Jenner has been President of the Royal College of Physicians, and although we believe that he will be invited to retain his office, we understand that he will decline to take upon himself the duties of this important position for another year. The interesting ceremony, of which we give a detailed account elsewhere, seems to be the climax of a life's work of no ordinary value to the profession which he so much adorns, and by the members of which he is so universally and deservedly respected. It is well known that it is mainly through Sir William's influence that the Colleges of Physicians and Surgeons have been brought to act in concert in building the new Examination Hall, and it is also certain that Her Majesty has consented to lay the foundation-stone of the building entirely through his mediation. To her appreciation of Sir William's successful care of her may be attributed her words of graceful praise, "The President of the Royal College of Physicians, with whom I have been long personally acquainted, and whose eminent abilities and far-seeing knowledge have justly placed him in the foremost rank of those who have benefited mankind."

THE GOVERNMENT COMMISSION ON HYDROPHOBIA.

WE have reason to believe that the eminent pathologists, Sir James Paget, Professor Burdon Sanderson, and Dr. Lauder Brunton, have, together with Sir H. Roscoe, who initiated the matter, consented to serve on the Commission to inquire into M. Pasteur's method of inoculation for hydrophobia; and that the Government intend to seek in addition the services of a few distinguished physicians, including Sir W. Jenner. As soon as the details are arranged the Commission are expected to proceed to Paris, personally to investigate M. Pasteur's proceedings and their results.

MILK ADULTERATION.

WE have lately drawn attention to a form of milk adulteration somewhat different from the time-honoured skimming and watering. The new offence consists in the addition to pure milk of the skim-milk obtained from the "cream separator." We commented, not for the first time, on the defective state of our law, which compels the public analyst to adopt as his standard of purity the poorest of cow's milk. There can be no doubt that genuine milk is sometimes found which contains as little as 11 per cent. of solids—viz., 2·5 per cent. of butter-fat and 8·5 per cent. of sugar, albuminoids, and ash. It is admitted by all that such milk is abnormally poor, and the selling of it a serious danger to the public health, and yet the public analyst is unable to stop its public sale, for the law most absurdly compels him in his certificate to state in figures the extent of the adulteration which has been practised, the quantity of water which has been added to, or the quantity of cream which has been removed from, the milk. If milk were a substance of constant composition, like sugar, this would be easy enough, for, thanks mainly to the labours of English analysts, the methods of analysis are now singularly accurate. But milk is a very variable mixture, and an analyst is therefore obliged to take as his standard of purity the very poorest milk he can find. Even then he is not quite safe, for it is asserted by many that milk may be drawn from a cow's udder which is even poorer than this standard. What the law ought to do is evidently to fix a limit of strength as regards fat and total solids, below which milk shall be deemed to be adulterated for the purposes of the Act. This would render the work easy and satisfactory, and would leave to the vendor no serious difficulty. We are glad to find from a report which has just reached us that this simple and satisfactory solution of the problem has already been attained by at least one enlightened board, which, however, is unfortunately in America, and not in England. It appears that in the State of Massachusetts an "inspector of milk" has long been a recognised official, but it was only at the commencement of the last official year that a new law gave him the power of attacking the evil efficiently. Mr. James F. Babcock, the present officer, is entitled the "Inspector of Milk and Vinegar," and his report for 1885, addressed to the Mayor and Board of Aldermen of the city of Boston, is an interesting and important document. Under the new law every carrier of milk must be licensed, and every vendor of milk in a "store, booth stand, or market-place" must be registered, the fee in each case being fifty cents. The inspector has power to enter and take samples of milk, butter, oleomargarine, and vinegar, and to lodge complaints, followed by legal proceedings when the law is deemed to have been violated. From April to December last 9853 inspections were made

Digitized by Google

and 110 complaints lodged, of which only five were dismissed. Under this vigorous action the percentage of adulterated samples of milk sank from 38·60 in April and May to 16·19 in November and December, and it can hardly be doubted that a still further improvement will be effected. A well-furnished city laboratory has been provided, and the report describes in detail the apparatus it contains, its cost, and the methods of analysis employed. The latter will be interesting to many of our readers, and may be briefly described. In the preliminary examination the specific gravity is first determined by a Piles's hydrometer, correction being made for temperature by means of a table given in the text. The standard temperature is 15° C. (59° F.), but the standard specific gravity is not given. We presume further analysis would be required if it fell below 1·033. The approximate percentage of fat is also in every case estimated by means of Feser's lactoscope, in which four cubic centimetres of the milk are diluted with water in a glass cylinder until black lines on a vertical white glass rod in the centre are visible. Graduations on the outer glass then give the result. If these two preliminary tests give doubtful results a more complete analysis is made, pretty much in the usual way, the fat being removed by boiling petroleum "benzine"—spirit we presume—and the sugar by the polariscope. This system is of course imperfect, but it is calculated to give concordant and tolerably trustworthy results. The chief fault seems to be that the fat is not directly weighed, and that, as we understand, the total solids and the solids not fat are not carried to constant weight. The milk standard is, as we have before mentioned, fixed by law. Milk is considered adulterated unless it contains 13 per cent. of total solids—namely, 3·7 of fat and 9·3 solids not fat. This is a somewhat severe standard, and possibly in England 3 per cent. of fat and 9 per cent. of solids not fat would be high enough. But, on the other hand, there is force in Mr. Babcock's remark, with which we may conclude: "The public have a right to demand that the milk supplied to them shall be of good *average* quality; and it is asserted that the present standard in Massachusetts is precisely this, and no more."

THE USE OF ANÆSTHETICS.

WE have deemed it necessary from time to time to call the attention of our readers to the subject of anæsthetic agents as employed in surgical operations, and more especially to the dangers which attend upon the use of chloroform when employed alone. The frequent occurrence of a fatal result from this agent, as recorded in our columns, has rendered it necessary for us to draw attention to the matter and seriously put the question to our surgical brethren as to whether they are justified in using chloroform as an anæsthetic, seeing that a considerable risk is of necessity associated with it, however carefully it may be employed. This question assumes much greater seriousness when it is remembered that large experience and careful investigation have proved beyond a doubt that the use of other agents which produce insensibility to pain is not accompanied with so much risk as attends the employment of chloroform alone. If no other anæsthetic were obtainable, we should have to balance the good results against the evil and be content with the former; but this is not the case. Although there are some drawbacks to the use of ether, inasmuch as it is not so manageable as chloroform, and, in the case of persons liable to emphysematous or bronchitic attacks, is attended with inconvenience and some risk, yet for the majority of adult patients this agent may be employed with comparative safety. Then, again, extensive experience with the safe and effective anæsthetic composed of one part of alcohol, two parts of chloroform, and three parts of ether, has demonstrated that it is not only as powerful in producing insensibility to pain, but that it is in a great degree less dangerous than chloroform. This form of anæsthetic is now used largely, both in hospital and in private practice, and a fatal accident from its use has rarely been recorded, whereas the announcement of a death from the use of chloroform alone is a matter now of almost weekly occurrence. We think it our duty to state that a surgeon is not justified in recommending the employment of chloroform as an anæsthetic whilst he has it in his power to make use of agents which are capable of producing the same effect in annulling pain without anything like the danger which results from chloroform when used alone. It is only fair towards a patient who is ignorant in these matters, and who places his confidence in his medical adviser, that if he is to undergo a surgical operation those methods which are the least dangerous as well as the most efficient should be adopted. No surgeon would at the present day recommend a patient with aneurysm of the popliteal artery to undergo ligature of the femoral before trying the less dangerous method of pressure, and no surgeon would think of performing the formidable operation of lithotomy in a case where a stone could be crushed. In either of these cases he is guided in his conduct towards his patient by the knowledge of the fact that one operation is as effectual and much less perilous than the other. In like manner we conceive it to be the duty of a surgeon about to perform an operation to employ the form of anæsthetic which is proved by experience to be attended with the least amount of risk. Chloroform is by far the most dangerous agent to employ; as a rule it should be discarded except in particular instances, such as in operations on children who bear it well, or on old persons who are afflicted with pulmonary complaints, to whom the use of ether is decidedly objectionable.

THE CONTAMINATION OF BRITISH UNIFORMS.

A MEETING of workwomen engaged at the Army Clothing Depôt at Pimlico, held last week at Portcullis Hall, Westminster, revealed the fact that the sanitary precautions taken some years since have of late been entirely abandoned. Eight years ago we clearly demonstrated how uniforms made in the private dwellings of the workers were often brought in contact with small-pox and scarlet fever patients. The Secretary for War at that time, Mr. Hardy, acknowledged that of the three viewers who examined the clothing brought from outside one had contracted small-pox during the course of the previous five years. Another viewer and his daughter suffered from small-pox just before the five years in question (1872-77). In 1878, when our revelations on the subject were published, a great alteration was made in the management of the Army Clothing Depôt, which we were assured was based on the following principles:—A slight reduction in the rate of wages, so that the Government might with greater facility compete with private contractors, the latter being even more likely to neglect the necessary sanitary precautions. All out-door work was in principle to be abolished. No new hand should be allowed to take work home, and it would only be continued with respect to some soldiers' widows and others to whom the State was morally indebted and who had no better means of subsistence; there were but very few such cases, and these would gradually die out. Thus the uniforms would ultimately be entirely manufactured within the walls of the factory, where the workpeople would enjoy healthy quarters, ample ventilation, and where the cloth could not be brought into contact with persons suffering from infectious disease. These promises have, however, been wholly forgotten. The workwomen say that their wages have fallen so low that their patience and powers of endurance are exhausted. Questioned in the House of Commons, Mr. Woodhall replied that the

Digitized by Google

average wages in 1884 amounted to 15*s.* 8*d.* per week, and in 1885 to 15*s.* 8½*d.* It seemed therefore as if there had been no reduction, and that is certainly the case so far as the amount of money paid is concerned; but the quantity of clothing made for this sum according to the present piece-work tariff is considerably in excess of what was formerly required. To earn this the women have to work long hours in the night. Overtime, however, is contrary to the stipulations of the Factory Act, and therefore the women take the work home. As a matter of form, it is said this is not allowed; as a matter of fact, it is the general custom. But for this, the average wages paid could never have been maintained at their former figure. About 500 women were present at the meeting in Portcullis Hall. They greeted with laughter the suggestion that they were not allowed to take work home. When those who were in the habit of taking work home from the factory were asked to hold up their hands, every hand was uplifted. Then, to make sure of the test, the workwomen who had not taken work home were called upon to hold up their hands, and not a single hand was raised. Hence it seems clear that the sanitary precautions deemed necessary and the Factory Act are both openly violated at the Army Clothing Depôt. Home work, with its attendant danger of infection, instead of being restricted to a few exceptional cases, is now, on the contrary, the universal practice. The Factory Act, stipulating that women shall work only ten hours, is flagrantly defied by their continuing at night, and in unhealthy, overcrowded homes, identically the same task which was begun during the day in the healthy and well-ordered State factory. How can we hope to suppress the sanitary defects and the illegal practices of the "sweater" in the East-end when in the West-end the managers of this model Government establishment contrive to evade the law? Economy may be a virtue, but it becomes the worst form of extravagance when it compromises public health. Nor is it fair to the public, who are anxious that those who work for the State should at least earn enough to afford means of living. We feel convinced that public opinion will support us in demanding that the Factory Act shall be duly observed, home work strictly suppressed, and the scale of prices so revised that the average of 15*s.* 8*d.* can be earned within the walls of the Government factory and within the working hours prescribed by the law.

LONDON DUST.

MR. MILLAR, the Vestry Clerk to St. George the Martyr, Southwark, has proposed to Sir Robert Rawlinson a comprehensive scheme for dealing with the dust and refuse of the metropolis. His suggestion is to reclaim the useless land from Tilbury to Southend by removing to it all the refuse of London. The Government for this purpose would have to engage wharves along the river which would be used as shoots by the various vestries and district boards, whence the dust would be conveyed to its destination by small tugs and barges. The cost of conveyance to Tilbury he proposes should be paid by a metropolitan rate, and the cost of reclaiming the land by the Government. Mr. Millar's scheme will certainly commend itself to those who regard this subject from the public health point of view, but it could not be carried out without interference with certain industries. Brickmakers would argue that the present system which is carried on in London dust-yards is necessary for the purpose of enabling them to manufacture bricks for the growth of London. Farmers have learnt to depend upon London road-sweepings and "soft core" for manure; and last, but not least, contractors have learnt to make sufficient profits out of London dust to make their influence felt by local authorities. But this industry is less remunerative than formerly, and as a result there is often a tendency on the part of the contractor to leave the dust in dust-bins rather than devote it to the uses we have indicated. Hence there has for some time been a growing feeling that some radical change was necessary in the method of dealing with the waste material of this large city. Efforts have been made by more than one métropolitan medical officer of health to bring to the notice of his sanitary authority the advantages of burning house refuse in some such manner as that practised in the north of England. Vestries have been taught continually that they must learn to think of dust-removal in its health rather than its economic relations. But the influence of the contractor and the force of custom have always stood in the way of any alteration of procedure. Mr. Millar's scheme will, we hope, revive the whole subject. Subject to regular removal from houses the money cost of dealing with refuse is an important consideration, and it is obvious that every effort would be made to utilise the material in some way that would make as much return as possible for the money expended in its collection. Mr. Millar calculates that the metropolis now pays £120,000 annually for this purpose. If his scheme be such as to cost no more than this, it is even then worthy of consideration, for the removal from houses would not then be dependent, as now, upon the requirements of the brickmaker or the farmer.

RUPTURE OF PREGNANT UTERUS; PORRO'S OPERATION; RECOVERY.

A COMMUNICATION by Professor Slawjansky to the Surgical Society of St. Petersburg, on a case in which he successfully performed Porro's operation for rupture of the gravid uterus, is published in the February number of the Paris *Annales de Gynécologie et d'Obstétrique*. Slawjansky states that he has collected 175 cases of the operation which was first practised by Porro at Pavia in 1876. It was performed by Dr. Prévot at Moscow in 1878, ten hours after rupture of the uterus, but the patient died the fifth day in consequence of hæmorrhage from the pedicle. C. E——, aged thirty-seven, within one week of full term, was knocked down by a tramcar while crossing one of the streets of Vassili-Ostroff. Considerable hæmorrhage ensued from the genitals, and the patient lost consciousness while being carried to her home. She was first seen in the clinique of the Imperial Academy of Medicine by Professor Slawjansky twenty-six hours after the accident. The patient was then quite conscious; skin pale; mucous membranes slightly cyanosed; ecchymoses on the inner side of the left eye and on the buttocks; abdomen very tender on pressure. Temperature 38·1° C.; pulse 138. Objective examination of the enlarged abdomen, conducted under chloroform, in consultation with Professor Bider, gave the following results: Immediately under the abdominal wall, and towards the left iliac fossa, could be felt the sutures in the fœtal head. Upwards and a little to the right the trunk of the fœtus and some of the ribs could be distinguished. The breech was above and a little to the right of the median line. On the right of the fœtus, over an extent equal to two hands' breadth, was experienced a sensation of decided resistance, but without defined outline. The fœtus was movable, heart sounds not audible. By vaginal examination the cervix could be felt with easily dilatable orifice admitting two fingers. Beyond the internal orifice the uterine wall was reached on the right side, and the edge of the placenta easily touched; but on the left the uterine wall could not be discovered, and, on practising bimanual touch, the fingers of the two hands could be approached until they were only separated by the abdominal wall. Penetrating more deeply and upwards, a fœtal foot could be felt, and, between it and the exploring fingers, the presence of the fœtal membranes. But nowhere could the edges of the uterine rupture be detected. All circumstances con-

Digitized by Google

sidered, *traumatic rupture of the gravid uterus* was diagnosed, and the necessity recognised for immediate delivery. Exploratory laparotomy having been decided upon, three hours after the patient's admission Dr. Matveef administered chloroform. The temperature was then 38·6° C.; pulse 138; respiration 25. The operation was performed under the strictest antiseptic precautions, and Dr. Fisher was the principal assistant. Immediately over the fœtal head an incision of two centimetres was made into the abdominal wall, and one of two millimetres into the peritoneum, giving issue to a mixture of bloody serosity, meconium, and cheesy flocculi. The hairy scalp of the fœtal head could then be felt in the abdominal cavity, and the parietes and peritoneum were divided with scissors to the extent of twelve centimetres, the dead fœtus seized by the head and extracted gently.. On introducing the hand into the peritoneal cavity with a view to extract the placenta, this was found firmly adherent, apparently to the outer surface of the womb, and it was thought preferable to withdraw that organ through the abdominal wound. It then became evident that the uterus, torn from side to side in its upper third, was completely everted. The placenta and membranes were completely adherent throughout their whole extent. The internal orifice was not visible, being bridged over by the membranes. The womb had thus the appearance of a mushroom, round the top of which the Fallopian tubes proceeded to their insertion. An elastic ligature having been placed on the cervix, the placenta and membranes were detached; the mushroom-like shape of the everted uterus was then still more perceptible. The cervix was now more firmly secured with a second elastic ligature, and the uterus and appendages removed with the bistoury. The pedicle was divided into two, and each portion secured by separate elastic ligature. While performing careful peritoneal toilette, evidences of general peritonitis became manifest, with deep redness of the intestinal coils and a dull velvety appearance of their surface. The pedicle was fixed in the lower part of the wound, the ligatures projecting through it and its edges closed with nine deep silken sutures. Powdering its surface freely with iodoform, covering it with two layers of iodoform gauze, a thin layer of sublimated wadding, and a hypogastric bandage, constituted all the dressing. The operation lasted forty-five minutes. The patient was removed into an isolated room, and on waking said she felt better, and the pains had left her. The pedicle stump dried up rapidly and separated on the twenty-third day. The sutures were removed on the fourteenth day, with the exception of the two near and beneath the pedicle, which were removed on the twentieth day. On the fifth day copious diarrhœa set in and lasted four days. The maximum of temperature was 39·1° C., of pulse 126. From the third day after the operation the urine contained some albumen, and occasionally a considerable number of red and white globules. The nephritic affection disappeared on the twentieth day, and on the thirty-sixth the temperature was normal.

CHOLERA AND WATER.

IN an address delivered before the South Indian Branch of the British Medical Association, Surgeon-General Furnell draws attention to the relation which exists between the water-supply and the prevalence of cholera in India, and at the outset he declares that the remedy against the recurring epidemics of this disease lies in the hands of the authorities if they will but have the courage to use it—namely, to provide the people with an uncontaminated water. Speaking generally of Southern India, and more or less of the whole of the immense continent, it is said that every hamlet, village, and town has a water-supply open, and easily open, to the foulest contamination. Detailing the special means by which water is fouled by the inhabitants of our Eastern Empire, Dr. Furnell asks two questions—namely, first, have we any proof that water contaminated with cholera dejecta will spread cholera? and secondly, have we any proof that a people supplied with a pure and uncontaminated water supply escape cholera? Proceeding to give instances which in India supply an affirmative answer to the first question, and of the crucial evidence obtained as to it, he states that as regards the second question the evidence procurable is circumstantial only. Indeed, improvements in water-supply have so generally gone hand in hand with other sanitary reforms that it becomes, as a rule, next to impossible to eliminate all other conditions, and to declare that immunity from cholera is the result of one improvement only. But in reference to the town of Pondicherry, there does appear to be reason, according to Dr. Furnell, to attribute the singular immunity from cholera which that place has experienced, at a time when such neighbouring towns as Cuddalore were severely infected, essentially to an improved water; and it is added that in so far as such sanitary improvements as are involved in securing cleanliness are concerned, Pondicherry is no better off than Cuddalore. Indeed, taking into consideration all other reasons alleged for the difference in the behaviour of cholera in these two towns, Dr. Furnell arrives at the conclusion that the unique water-supply of Pondicherry, free as it is from sources of contamination, supplies the only explanation. The effect of the paper is to leave a strong impression of the need of the improvement of the water-supplies for the populations of India, and as such it will receive the support of all interested in the prevention of cholera, irrespective of their views as to the nature of the contagium to be dealt with.

THE CHEAP DINNER MOVEMENT.

THE movement for supplying wholesome food and dinners to the people at a cheap rate has received a further development from the able and interesting paper read by Captain Wolff on Thursday week last at the Parkes Museum of Hygiene. The audience, consisting of the Fellows and Members of the Sanitary Institute, and presided over by Dr. Richardson, listened with great interest to the essay, and carried out afterwards a very useful discussion. Captain Wolff, who has personally traversed the greater part of the metropolis in order to determine where the wants of the people are most pressing, displayed the results on what may be called a food map of the metropolis. In some of the quarters thus delineated it may truly be said that there is not only deficiency of provisions at a moderate cost, but that the means for the preparation of food of any kind in a wholesome form are completely absent. There are neither kitchens, nor fires, nor cooks. In the wildest parts of the world it would be possible to find better provision than here in the midst of civilisation; and how it can be expected that men under such conditions should live a law-abiding, civilised existence? If a man drinks beer he thinks beer, said Samuel Johnson; and equally true is it that, if a man is forced to feed as wolves feed, he will grow wolfish and out of the ordinary rules of human government, however wisely those rules may have been framed for the common good. The design now suggested proposes to meet the dangers and the difficulties incident and consequent on starved revolt by sensible prevention of danger. It asks for no charity which, as the chairman insisted, cannot be a permanent aid; but it opens to all thoughtful persons a mode of applying their time and their money in a way that shall yield a return for both, and confer a national service, which it were well to render while times are still peaceful and the masses loyal. The subject is not technically one which concerns the profession

Digitized by Google

of medicine more than other professions or callings; yet we are glad to see that medicine is taking the lead in the practical working of it. If Dr. Richardson and those who are striving with him can but succeed in establishing half a dozen kitchens on a model scale, the success will, we seriously believe, be quickly assured. The movement would rapidly grow, and in a few months the metropolis, in every part of it, would have comfortable dining quarters at which the poorest would be fed wholesomely, rationally, and comfortably. A public kitchen and dining-room in rivalry to every public-house would be the grandest counterblast to public intemperance that was ever set up.

HYDROPHOBIA AND THE DOG REGULATIONS.

WE are glad to see that police notices have been extensively advertised to the effect that the order of Dec. 4th, 1885, which requires that all dogs while in the streets of the metropolis (within six miles from Charing-cross) not being led by some person are to be muzzled is still to remain in force. There can be no doubt that these regulations, and the consequent wholesale destruction of dangerous, ownerless, and useless curs have been successful in reducing the number of cases of rabies and hydrophobia. Indeed, if proof be needed, it is furnished by a return, moved for by Sir Richard Cross, and issued on Wednesday last, which shows that since the order for muzzling was put in force on Dec. 10th the decrease in the number of cases of rabies reported has been marked. In December last forty-six cases were reported, in January twenty-seven, and in February fourteen. The number of deaths from hydrophobia reported in the metropolitan district was twenty-six in 1885, and one in January, 1886. Considering this great increase in the usual annual number of cases, it is no wonder that we have been passing through what is generally called a "hydrophobia scare"; for once in a way, however, a "scare" has made its influence widely and, let us trust, permanently felt, and has so far had good results. It is to be hoped that when the present epidemic has died away and this terrible disease is again almost lost sight of by the public, the authorities will still continue to exercise some sort of control over wandering and ownerless dogs.

NEW FRENCH MILITARY SANATORIUM.

THE arrival at Toulon of a transport with two hundred invalids from Tonquin has caused no small sensation and alarm. The evidence collected shows that the cholera was not imported from Tonquin; and, indeed, there had been cases of cholera at Marseilles some ten months before the *Sarthe*, the incriminated vessel, reached the port of Toulon. Nevertheless an unpleasant impression prevails, and when it was announced that the sick men were to be located at the island of Porquerolles a perfect outcry was raised. The clamour was so loud that the Minister of Commerce, M. E. Lockroy, has been compelled to visit Marseilles, Toulon, and Porquerolles. The latter place is the largest of the Golden Islands, or Isles d'Hyères. It is situated six miles out at sea and nine miles from the well-known winter station of Hyères. As a healthy and beautiful spot nothing better could be desired. The island is divided into seven ranges of small hills, with innumerable nooks and sheltered corners where the sea air may be enjoyed without disturbance. The rich vegetation, the pine-trees, thyme, myrtle, and tamarisk, perfume the atmosphere with balsamic exhalations. For a sanatorium it would be difficult to find a better position, but for the fact that it is already used for a convalescent hospital for soldiers coming from Africa. There are also small local interests that might be injured by the presence of dangerous and contagious forms of disease imported from the colonies. The sanitary condition, it must be added, of the existing hospital is most unfavourable. It is a wretched old building, with no sanitary contrivances whatever, and very insufficient means of ventilation. Under all these circumstances it would be much wiser to select the neighbouring island of Portcros. As may be gathered from its name (a derivation of *port-creux*), it has a better harbour, and has the advantage of being further out at sea. Also there are barely fifty inhabitants in the island, and, like Porquerolles, it possesses rich balsamic vegetation with hills affording good shelter from the winds. Here tent or field ambulances could be established which would be far safer than the malodorous and old structure called the hospital of Porquerolles. We understand that M. Lockroy himself favours this solution of the difficulty, and trusts it will be acted upon without further loss of time. With so many beautiful sites and the exceptional climatic advantages of the Riviera, the French Government should be able to provide its soldiers with all that is needful for their restoration to health.

DOCKED FEES.

A CORRESPONDENT writes:—"The practice of giving sovereigns instead of guineas to medical men is one which, I think, is worthy of notice on account of the great destruction of good feeling which it occasions. Its origin is obscure; possibly it dates from the replacement of the guinea as a coin by the sovereign. The practice is almost confined (curiously enough) to the aristocracy and to those who, being perhaps distantly related to some member of that body, seek to emphasise the fact by the adoption of their defects—in the same way as parasites of Royalty have from time to time imitated the physical imperfections of a Sovereign—both, possibly, on the principle that 'imitation is the sincerest flattery.' I do not mean to say that this habit is universal among the aristocracy, many of whom discharge their debts not only with exactness, but with generosity. Now, after the authentic history of the two knights who fought about the colour of a shield, and found on looking at both sides of it that it was, after all, both gold and silver (the shield was, without any doubt whatever, in reality a guinea), I feel that no other method can be so conveniently adopted as that which led to the resumption of harmonious relations in the case above recorded. First, from the point of view of the "upper ten." The guinea is an obsolete coin; small change is a nuisance. What follows? To dock the fee and give a sovereign? Nay; if the airs of a grand seigneur are to be adopted, by all means give another sovereign, or at least gold. Now, the practice is *not* kept up from inadvertence; for it is not unfrequently the subject of animated discussion among members of the aristocracy themselves. From the point of view of the medical man, it means, first, pecuniarily (a consideration of the least importance on this occasion), a tax of 5 per cent., a loss on an income of 2000 guineas of £100. On each occasion on which a sovereign is tendered singly, it means that the good nature, forbearance, and good manners of the medical man are presumed upon. If a lump sum is paid in this manner, it means that the patient deliberately withholds part of his debt. Let each person in the habit of acting in this way think what he would say to a tax of 5 per cent. being levied on all his income by each private individual through whose hands it passed; what would he or she say to such a proceeding in the case of such a commonplace matter as the price of a horse or the payment of a bet? But this is the least part of the matter. The fee tendered by a patient is not *only* a payment. It should be rather the outward and visible sign of gratitude for benefits received, which can never be entirely paid for by money. There are many little kindnesses constantly rendered by us for which we neither ask, nor expect, nor would receive money payment; our only reward is the gratitude and friendly regard of our patient; and it is just this, the dew on the grass, the bloom on the

Digitized by Google

grape, which is by this act necessarily destroyed. I will go further, and say that most of us would willingly provide the shilling rather than lose the sentiment. As concerns the conduct of our profession, I am far from hinting or advising that they should on all occasions call the attention of a patient to a 'docked fee,' but opportunities arise on which it is possible to correct erroneous ideas without giving offence or disturbing friendly relations. Such opportunities should not be missed for the want of a little moral courage; but medical men should remember that they owe it to their brethren to do what they can to prevent the establishment of wrong precedents, and be ready to give themselves a little trouble for the good of their profession."

FEMALE LABOUR IN COLLIERIES.

THE movement in favour of the abolition of female labour in collieries does not, it would seem, give general satisfaction among the class which will be chiefly affected by it. At a recent meeting near Wigan a considerable number of persons discussed the changes proposed and entered a protest against them. Among them were 100 pit girls in working dress. This is described as consisting of a closely-fitting black padded bonnet, blue flannel loose jacket with sleeves, dark-blue flannel trousers, dark-blue short skirt with rough apron, and clogs. The subject of female labour was considered at length by the speakers present, and the condition of the pit women reviewed in various aspects. Their muscular development and physique generally were said to be of a superior order, and the advantages of occupation in the open air favourably contrasted with the evils engendered by ill-ventilated workrooms. Domestic life, it was stated, did not suffer from the long daily absence of the women from their homes. On the contrary, this very fact gave an additional charm to household duties in the evening. The use of a modified masculine dress was considered to be decent in itself, and to be justified by necessity. The colliery work was admittedly hard, even harder than was usual or suitable for women, but the want of it would deprive thousands of women of their livelihood: and the agitation which aimed at this result was, the speakers believed, the work of interested trades unionists, and intended solely to increase the wages of pitmen. That this is a one-sided statement of the case is manifest, but it must also be admitted that the arguments used in support of it are not merely specious. It is not to be denied that occupation in the open air is good for women as well as men, and it is only to be expected that muscular strength should be the effect of hard work in such conditions on those who can stand it. The strain encountered in colliery work by women is, however, allowed, even by the advocates for their continued employment, to be unduly severe, and the attendant circumstances are certainly better avoided if possible. The dress cannot, indeed, be blamed as conspicuously indecent, but few persons would regard it as becoming or womanly. This is, no doubt, to some extent a matter of sentiment, and we have therefore no wish to magnify its importance in the face of direct advantages with regard to warmth and ease of movement. It is, however, only one of many circumstances in a masculine calling which must tend to obliterate the right and natural degree of character-distinction between the sexes, to the injury of home life. Women in the northern coal districts do not seem to feel the want of work at the pit mouth. There is no reason to suppose that their Lancashire sisters will ultimately suffer if deprived of it. At the same time it is only fair that custom and the state of trade should be considered by the authorities in making this change, and that the transference of the women's work to men should be a gradual process.

THE ISLINGTON MEDICAL SOCIETY: MULTIPLE PHLEBITIS.

AT the Islington Medical Society on Tuesday, Dr. Morison gave the details of an interesting case of multiple phlebitis, or, as he properly suggested, multiple thrombosis. The patient was a gentleman of temperate habits, with no history of ague or syphilis, gout, or other constitutional disease. There was no other permanent disease to be detected, though in the course of his illness, which extended over two years, he had two attacks of pleurisy. No post-mortem examination was allowed. The urine was of ordinary specific gravity, and free from albumen and sugar. The affection occurred in both legs and arms, and finally gave rise to striking varicosity of the veins of the abdomen. Two or three curious symptoms deserve special notice. One was a swelling of the uvula, with considerable oozing hæmorrhage from it. Another was deep melancholia, produced by the long and, as it proved, incurable persistence of the disease in spite of all sorts of remedies, which led to an almost suicidal refusal of food. Not the least striking feature of the case was the constantly subnormal temperature of the patient. Generally his temperature was 97°; but for two or three days before death Dr. Morison found it much lower. He was careful in his observations of this point. On Aug. 5th, 1882, the patient starving, it was 94°. On the 6th he took some food, and it rose to 96°. On the 7th the breath was cold, and the temperature in the rectum 91°; the intellect clear; pupils normal or slightly contracted: heart's action regular. On the 8th, at 8 P.M., death took place. The pulse, too, was slow (under 70), and there was but little tenderness in the affected veins. Such facts confirm the justice of the view that regards thrombosis as not a mere inflammatory affection of the veins, but rather a blood disease. Even when the patient had his attacks of pleurisy his temperature was only 100°. At the same meeting Dr. Stokes gave particulars of a case of scirrhus of the left chest in a girl of eighteen, which simulated pleurisy so closely that she was twice tapped, without much relief.

SURGICAL TREATMENT OF BRONCHIECTASIS.

THE valuable paper contributed by Dr. C. T. Williams and Mr. Rickman Godlee to the Royal Medical and Chirurgical Society provoked considerable discussion, and may be regarded as marking a decided step in advance in the surgical treatment of suppurative disease of the lung. From our report it will be seen that the following features were the main topics of discussion. All the speakers commented on the difficulty of diagnosing bronchiectasis, and special stress was laid by Drs. Goodhart, Barlow, and Coupland on the difficulty that offered when a bronchus was totally obstructed. Under these circumstances the absence of breath sound, loss of vocal fremitus, and almost absolute dulness gave a decided clinical resemblance to effusion into the pleura; and in most of the illustrative cases the diagnosis was only made at the post-mortem examination. Most speakers concurred in the difficulty of forming any positive conclusion as to the existence of pleural adhesions. The majority of those who joined in the discussion argued that the most favourable cases for operation were not those of simple bronchiectasis, but those in which there was added a fibrosis or chronic pneumonia around the bronchial dilatation. Indeed the authors of the paper considered that simple multiple bronchiectasis was not likely to be relieved by paracentesis. Other centres of interest were the question of danger from hæmorrhage and the best method of exploring to discover the site of the bronchial dilatation. Sir Andrew Clark believed that the reason why hæmorrhage was slight in operations in such cases was because fibrosis being generally present, the arteries were also sclerosed and their

Digitized by Google

calibre diminished. The argument is perhaps supported by the freedom from hæmorrhage in some cases, but it might be urged that a sclerosed vessel would be more likely to remain patent, contraction of the middle coats being prevented. That danger may arise from hæmorrhage was testified to by Mr. Godlee and Mr. Gould, who also spoke on the value of an aspirator in the detection of the situation of cavities.

FOOTBALL.

IT is pleasant to have to chronicle under this heading some items less sombre than the usual ones of contusions, fractures, and deaths. The Rugby Union and the Football Association—who differ much, at least so far as the game of football is concerned—on Saturday last entered into praiseworthy combination in the cause of charity. During the afternoon representative matches were played at the Oval in the presence of the Prince of Wales and many thousand spectators. In the evening a smoking concert was held in the principal room of the Holborn Restaurant, a varied and capital entertainment being provided and enthusiastically received by a crowded audience. This "charity festival" will probably result in a substantial sum being left at the disposal of the promoters, who announced that the festival was to be held "on behalf of the London charities." This is comprehensive, if a little vague. We heard it rumoured, however, that the greater part of the sum raised was likely to go to King's College Hospital in response to the recent appeal. Be that as it may, we trust that the hospitals, which are very noticeable "London charities," and just now sadly in want of funds, will not be forgotten. We are glad to see that the president of the Football Association, Major Marindin, was at the recent general meeting of that body successful in passing the following new rule: "No player shall wear any kind of projection on the soles or heels of his boots, with the exception of flat leather bars, to be arranged in accordance with patterns approved by the committee." Any measure calculated to diminish the present painfully frequent occurrence of accidents must be warmly welcomed. It is interesting to note that the representatives of Guy's have this year been successful in both the Rugby Union and Association inter-hospital cups.

AMENDMENT OF SANITARY LAW.

THE Association of Public Sanitary Inspectors have issued a report emanating from their council, in which they plead for greater power, greater responsibility, and increased emoluments. They point out that the sanitary inspector should initiate proceedings on behalf of the local authority for the abatement of nuisances, and should not await the instructions of the authority for this purpose. As a matter of fact, in some districts this course is already adopted, and is found to work well; in others, where there is closer adherence to the formality of the law, a preliminary or informal notice is served by the inspector, and this, in cases where the first notice is disregarded, is followed by a legal notice signed by the clerk to the authority. This is perhaps the most satisfactory method of overcoming the difficulty created by the law requiring that the local authority should institute proceedings. Sanitary authorities rarely meet more often than once a fortnight or once a month, and it is distinctly prejudicial to the public health if no notices are served until after instructions have been given for this purpose by the authority to its officer. Under the Food and Drugs Act the authority appoints its officer to act as purchaser, and upon the purchaser devolves the duty of instituting proceedings where food or drugs submitted to the analyst are found to be adulterated. It was obviously not the intention of those who drafted the Act that the authority should interfere with the officer so long as he performed his duties faithfully, but in practice authorities often decide in every case whether offenders shall be prosecuted. We fear, therefore, that the Association of Public Sanitary Inspectors, even if the law put them in the same position as the purchaser under the Food and Drugs Act, would not be materially benefited by this change. Local authorities have it in their power, and frequently exercise that power, to deprive the sanitary inspector of all freedom of action, and would doubtless continue to do so were the law amended in the manner indicated; but if local authorities were improved, much good would come from an alteration in the position of sanitary inspectors. Another desirable modification of existing law is pointed out in the report: it is of frequent occurrence that when proceedings are instituted with regard to neglect to carry out an order of a local authority, either a nominal fine is inflicted or no punishment whatever is awarded. The report recommends that the minimum penalty should be specified in every Act, and that it should thus be rendered impossible for magistrates to permit offenders who have been convicted to escape without punishment. We are glad to see the sanitary inspectors showing in so marked a way a proper appreciation of the value of their work.

IMPORTANT DISCOVERY OF RARE METALS.

THE necessity for minute accuracy in chemical analysis has just been illustrated in an important discovery by Dr. Strohecker of Frankfort. Somewhat extensive diluvial deposits of brick clay exist at Hainstadt, near Seeligenstadt. The bricks made from this clay vary considerably in colour, according to the temperature at which they are burnt, but the cause of the variation has never before been suspected. It now appears that the layers of this clay are singularly rich in several metals hitherto very scarce, particularly cerium, glucinum, lanthanum, didymium, and yttrium. The first two of these metals are present in such quantities that a more abundant supply may be expected. Ceria, in the form of hydrate, constituted 9·4 and 13·4 per cent. of the clay in two layers analysed, and the colour of the bricks seems to be mainly determined by its presence, for the quantity of iron present was very small. The discovery is therefore of immediate value, and will doubtless lead to further researches on the elements, which may prove to have much more importance in the economy of nature than has been supposed. It is evident that we must not neglect these little-known elements, for, apart from their scientific interest, we cannot tell what undiscovered uses may lie in them. We do not know, indeed, whether they are really as scarce as has been supposed.

VEXATIOUS LITIGATION IN THE UNITED STATES.

A MEDICAL MAN in New York has been mulcted in the sum of 500 dollars for erroneously reporting a case of small-pox, and thus "starting the machinery" by which it was sent to the small-pox hospital; and two Philadelphia medical men have recently been successfully sued for damages by a patient whom they certified, negligently as it was asserted, to be insane, and so were the means of placing in confinement. Such facilities for vexatious litigation exist in the United States that, according to the *Medical News*, "there is much hesitation on the part of physicians to furnish a certificate of insanity, even in cases in which in their judgment it clearly exists. Some positively decline, while others do not act until the disease is so manifest that an average juryman may come to a conclusion. A procedure ostensibly intended to protect the sane may in its practical operation become the means of doing injustice to that class of the insane whose only hope of recovery is

Digitized by Google

treatment in the early stage, and before decided changes and chronic conditions have become permanently established." An opinion is further expressed, which is as applicable to the existing state of things here as across the Atlantic, that some further legislation is required to protect medical men from vexatious litigation, or that the courts should clearly define and determine their rights, privileges, and exemption from responsibility.

GUSTAVE FLAUBERT.

THE publication by M. French Sheldon of an English version of Salammbô has once again opened the question of Flaubert's professional status. It has been assumed from internal evidence afforded both by this realistic work and by the fragments of the "Temptation of St. Anthony" that Flaubert was a medical man; but this common belief is, we are convinced, founded on a misconception. Both his father and brother were well-known surgeons—a circumstance which probably suggested the remark made by Sainte Beuve, in criticising the works of Gustave Flaubert, that the author handled his pen with as much facility as "the others" handled the scalpel. The father was for nearly thirty years one of the surgeons of the Hôtel Dieu at Rouen, and was the author of a well-known text-book on Surgery, besides several papers on the Treatment of Wounds. Gustave, who had a passionate admiration both for his father and his elder brother, commenced the study of medicine, and so acquired some knowledge both of anatomy and physiology; but he soon abandoned his scientific studies, and devoted his attention to literature and the production of those realistic works of art with which his name will always be associated.

THE ACADEMICAL COSTUME OF MEDICAL MEN.

IT may have occurred to many, as it undoubtedly occurred to some, of our readers who were present at the Royal ceremony on the Embankment on Wednesday last, that the occasions on which medical men appear in public in academical or any other characteristic costume are remarkably few. The clergy display their hoods every Sunday, and as a matter of fact are popularly held to be almost monopolists of academic distinction. We are not of those who attach very great importance to the setting of a good picture, but it certainly is possible that the throwing aside of all class and professional marks of distinction has the drawback that a profession which in fact, even more than in name, is emphatically a "learned" one, has ceased to command that respect in the eyes of the community at large to which it is unquestionably entitled.

TUBERCULOSA VERRUCOSA CUTIS.

THE well-known intractable inflammatory patches on the hands of those engaged in making examinations of dead bodies is attracting considerable attention at the present time. Dr. Wilks described them in 1862 under the name Verruca necrogenica, and attributed them to the constant irritation of the skin from the acridity of the morbid fluids of the dead body, but he did not notice any systemic infection. In France, where this condition is known as the "tubercule anatomique," some of the Hôpital St. Louis physicians, such as Besnier and Vidal, have long suspected their tubercular nature; and Tscherning, Merklen, Karg, and others have reported cases where subcutaneous nodosities developed up the arm with implication of the glands, followed by tubercular infiltration of the lungs. In the discussion of Verneuil's case it was related that Laennec carried one of these warty patches for some years, and eventually died of tuberculosis. In the last issue of the *Vierteljahreschrift für Dermatologie und Syphilis*, a number of cases of these patches are collected by Drs. Gustav Riehl and Richard Paltauf under the title of Tuberculosis verrucosa cutis. Some beautiful plates are appended showing their histological structure, resembling lupus, though more superficial and containing more numerous bacilli. It does not appear that any of Riehl's cases were followed by tuberculosis of the lungs.

"THE LAW AND THE LUNATIC."

THERE have been digests and commentaries without number called forth by the long-persisting agitation for reform of the Lunacy Laws; but a paper read before the Statistical and Social Inquiry Society of Ireland on Jan. 19th last, and since issued in the form of a pamphlet, seems to us to have the strongest claims on the attention of the profession and the Legislature. The *résumé* is admirably done, and the suggestion with a view to the provision of Observation hospitals, or, better still, Observation wards, in connexion with general hospitals, is on the same lines with the scheme we propounded in these columns in 1875-6, and which was submitted by our commissioner, Dr. Mortimer Granville, to the Select Committee of that date. We commend Dr. George Sigerson's *brochure*, "The Law and the Lunatic," to the attention of our readers.

AMENDMENT OF THE MEDICAL ACTS.

IT is still the intention of the Government to introduce a Bill to Amend the Medical Acts, in the sense of requiring full qualification in the three branches of the profession as a condition of registration; of giving direct representation to the profession, &c. It would of course be altogether premature to discuss the question now. But if Parliament survives the rocks ahead we may hope soon for the introduction of the Bill, and we shall then offer such criticisms on it as it may seem to require.

NEUROLOGICAL SOCIETY OF LONDON.

DR. HUGHLINGS JACKSON delivered, in the capacity of President of the new Society, an inaugural address at the National Hospital for the Paralysed and Epileptic on Wednesday last. The chief object of the address was to show the wide extent of neurology as it is to be studied by the Society. The address teems with most valuable suggestions in the various departments of neurology. A vote of thanks to the President for his address was proposed by Dr. Burdon Sanderson and seconded by Dr. Bristowe.

ARTIFICIAL COCAINE.

MERCK is said to have prepared cocaine by synthesis. Cocaine is benzoic methylecgonine. Benzoic ecgonine is treated with iodide of methyle in slight excess, in the presence of methylic alcohol at 100° C.; the excess of iodide and methylic alcohol is driven off by heat; from the resulting syrupy liquid cocaine is extracted. This artificial cocaine melts at 98° like its prototype, and it possesses all the reactions of the natural product.

ROUGH PITCHING IN LONDON STREETS.

IT is strange that, notwithstanding the improvements which have been effected in the paving of roadways generally throughout the metropolis, street-crossings and the little carriage-ways leading to private houses should have been almost uniformly neglected. In walking down the right side of Piccadilly from the circus—that was—to Hyde-park-corner, the pedestrian has to cross some thirty of these agonising bits of rough pitching, and if he happen to wear thin boots or to labour under the miserable disadvantage of tender feet he will not fail to execrate the perversity of the

Digitized by Google

public or private authorities by whose neglect he is tortured. There surely need be no great difficulty in finding a remedy for this nuisance.

A MOST DISGRACEFUL HOAX.

A LETTER appeared in the *Daily Telegraph* of Thursday, from Mr. C. L. Todd, Secretary to St. George's Hospital, saying that a cheque for £1000, the receipt of which had been acknowledged in that paper on the previous day, had been returned unpaid, marked, "No account." We do not envy the practical joker whose sense of humour is gratified by such unfeeling and very foolish conduct.

ON the 18th inst. the death occurred, after a short illness from acute pneumonia, of Mr. John Fremlyn Streatfeild, F.R.C.S., senior surgeon to the Royal London Ophthalmic Hospital, ophthalmic surgeon to University College Hospital, and Professor of Clinical Ophthalmic Surgery in the College. Mr. Streatfeild received his professional education at the London Hospital, and became a member of the Royal College of Surgeons in 1852. He was employed during the Crimean War as an assistant-surgeon to the British Hospital at Smyrna; but on his return to England devoted himself entirely to ophthalmic surgery, in which he attained a considerable reputation. He obtained the Fellowship of the College of Surgeons in 1862, and made various contributions to the literature of his department of practice. We hope in an early number to give a more detailed account of his life and work.

WE are requested by the Registrar of the Royal College of Physicians to state that he desires to express his regret should any letters addressed to him on the subject of the ceremony which took place on the 24th inst. not have been answered, his excuse for such apparent want of courtesy being the great increase of correspondence which that ceremony occasioned.

AN election for a curator of the museums of the Royal College of Surgeons in Ireland was held on Thursday, the 18th inst., when the Council appointed Dr. Alexander Baillie McKee to the post, at a salary of £250 a year. Dr. McKee is a graduate in Arts and Medicine of the University of Dublin.

THE Dublin Hospitals Inquiry Commission, having completed the task of receiving evidence, has, we learn, commenced to prepare its report, which will probably be ready for presentation to Parliament in the course of three or four weeks.

PROFESSOR GERHARDT, of Berlin, has had the misfortune to break his arm through his foot slipping when getting out of a railway carriage at the Central Railway Station in Berlin.

MR. PETER C. LITTLE, F.R.C.S.I., died last week at his residence in Amiens-street, Dublin, after a lingering illness, aged fifty-three years.

NATIONAL HEALTH SOCIETY.—The success attending the comprehensive course of Health Lectures recently delivered at Bayswater by Dr. Schofield has encouraged the National Health Society to commence a similar course at the Town Hall, Kensington, to be inaugurated by H.R.H. Princess Christian on Wednesday, March 31st. The subjects of general health, causes of diseases, dress, food, and home nursing will be treated in turn. The Health Lectures will be followed by ambulance classes, in which practical instruction will be given in nursing, first aid in accidents, bandaging, and stretcher drill.

OPENING OF THE NEW MEDICAL EXAMINATION HALL BY THE QUEEN.

ON the 24th inst. the Queen gave evidence of the interest which she has ever taken in the progress in her realms of the medical profession—a profession on which the prosperity, as gauged by the health, of her subjects is so largely dependent, by attending in semi-state to lay the foundation-stone of the new building upon the Embankment, which the ancient Corporations of Physicians and Surgeons are erecting for the purpose of a conjoint Examination Hall. Encouraged by the bright and warm sunshine weather, in such glaring contrast to that experienced during the last few weeks by residents in the metropolis, spectators began to line the route of Her Majesty's progress at an early hour of the morning, although the ceremony was not arranged to take place until after noon.

The site of the proposed building lies within the precincts of the Savoy, and at this place the band of the Scots Guards were stationed and played at intervals whilst the guests were arriving, amongst whom were the Duke of Northumberland, Earl Spencer, the Lord Chancellor, Lord Granville, Sir Lyon Playfair, the Lord Mayor, the Deans of St. Paul and Westminster, Sir John Lubbock, and Canon Duckworth. The site was covered with a marquee, which was very handsomely and effectively decorated for the occasion. The Embankment front was lined out to the full extent of the frontage of the new building with Venetian masts bearing floating banners and tasteful trophies of flags, triplicate. The Royal entrance, which was at the eastern end of the marquee, was made charming with flowering plants and Indian tapestry artistically disposed; while above it was a flagstaff, from which, in due course, the Royal Standard was displayed. In the interior was a handsome arcade in crimson and gold, supported by columns clothed with ferns, which led to the Royal seat and the foundation-stone. Around this special scene of the ceremony a horseshoe-shaped enclosure, slightly rising in the rear, covered with crimson cloth, bore a number of chairs for the high officials of the two Colleges. Behind this enclosure the remaining area of the marquee was laid out as an amphitheatre rising in tiers of benches, each numbered, for the reception of the general visitors, and the interest shown in the ceremony was evidenced by the fact that by 11.30 almost every one of these seats was occupied. Soon after the arrival of the guard of honour, which consisted of a company of the 3rd Battalion of the Grenadier Guards, a company of the Medical Staff Corps, and a company of the Artists' Volunteer Corps, at noon the officials of the two Colleges arrived upon the scene in accordance with the programme given in our last issue. Shortly afterwards the Prince of Wales, the Duke of Cambridge, the Princess Louise, the Marquis of Lorne, the Duke of Abercorn, the Archbishop of Canterbury, the Prince and Princess Christian, and the Duke of Connaught arrived, and waited the arrival of the Queen. At 12.30 a burst of cheering from the crowd outside announced the approach of Her Majesty, who, attired as usual in black, was met at the entrance of the marquee by the Royal group, the Chancellor of the Exchequer, the Chancellor of the Duchy of Lancaster, and by the Presidents of the two Colleges. Sir William Jenner and his colleague, Mr. Savory, led the way to the dais, where Mr. Childers and Mr. Engleheart, the Clerk of the Council of the Duchy, were waiting to receive Her Majesty, and lead her to her chair of state. Directly this duty had been performed, and the cheering had subsided, the choir of the Chapel Royal, Savoy, sang the National Anthem, the assembly joining in unison with admirable effect. A prayer, taken chiefly from the prayers of Francis Lord Bacon, a circumstance which accounted for the quaint-

Digitized by Google

ness of the language, was then offered by the Archbishop of Canterbury, and the choir afterwards intoned the Lord's Prayer and sang a hymn.

Mr. Savory, with Sir William Jenner standing by his side, then read the following joint address of the two Colleges:—

"We, the Royal College of Physicians of London and the Royal College of Surgeons of England, who owe our foundation to Royal favour, and to whom for many years the responsible duty of granting diplomas in Medicine and Surgery has by Royal Charter been entrusted, with a view to the further advancement of medical and surgical education, have recently combined for the purpose of establishing joint examinations in Medicine and Surgery and the science on which they are founded. We hope by this means not only to remove many of the existing difficulties in the way of students, but also to render the examinations more complete and satisfactory. And in order to promote the convenience and efficiency of this important step, we have undertaken to erect this hall, in which the examinations will be conducted, and which will be entirely devoted to that purpose. We cannot but regard it as a happy omen of the future success of this undertaking that your Majesty has been graciously pleased to inaugurate this good work by your Majesty's presence here to-day. And we desire to express to your Majesty our grateful sense of the distinction which has been thereby conferred on the two Colleges and the profession. In witness hereof we, your Majesty's loyal and dutiful subjects, have caused our common seals to be hereunto affixed this 24th day of March, 1886."

To this Her Majesty, in a clear but low voice, replied:—

"I thank you for your loyal address. It is with sincere pleasure that I lay the foundation-stone of the building which you propose to erect. I cordially concur in the hope which you have expressed, that this undertaking—in which I take a deep and personal interest—may largely contribute to the further advancement of medical and surgical education. The establishment of this hall is mainly due to the efforts you have made in conjunction with the President of the Royal College of Physicians, with whom I have been long personally acquainted, and whose eminent abilities and far-seeing knowledge have justly placed him in the foremost rank of those who have benefited mankind." (Great cheering).

Her Majesty then placed with her own hands a number of documents relating to the Colleges of Physicians and Surgeons, copies of THE LANCET, *The Times*, and *Morning Post*, and some coins and medals, in two glass jars, which were fitted into a cavity in the bed of the stone. An enamel photograph of Her Majesty, by Mr. A. L. Henderson, was, with her approval, also deposited in one of the jars. An elegant silver gilt trowel, appropriately inscribed, designed, and manufactured by Messrs. Hancock and Co., of New Bond-street, was then handed to Her Majesty by Mr. Stephen Salter, and the stone, which bore the following inscription, was lowered to its bed:—

VICTORIA,
Queen of Great Britain and Ireland,
Empress of India,
Laid with her own hand
This Stone.
24th March, 1886.

Her Majesty then gave the stone three taps with a black ebony mallet, which was handed to her for the purpose, and declared it well and truly laid, amid the loudest and most enthusiastic cheering.

The following gentlemen were then presented to Her Majesty by Sir William Jenner, Bart.:—The President of the Royal College of Surgeons, William Scovell Savory, Esq., M.B. Lond., F.R.C.S., F.R.S.; the Senior Vice-President of the Royal College of Physicians, Edmund Lloyd Birkett, Esq., M.D. Cant., F.R.C.P.; the Senior Vice-President of the Royal College of Surgeons, John Wood, Esq., F.R.C.S., F.R.S.; the Junior Vice-President of the Royal College of Physicians, John William Ogle, Esq., M.D. Oxon., F.R.C.P.; the Junior Vice-President of the Royal College of Surgeons, Henry Power, Esq., M.B. Lond., F.R.C.S.; the Treasurer of the Royal College of Physicians and Chairman of the Building Committee, Dyce Duckworth, Esq., M.D. Edin., F.R.C.P.; the Registrar of the Royal College of Physicians, Sir Henry A. Pitman, M.D. Cant., F.R.C.P.; the Architect of the Examination Hall, Stephen Salter, Esq., F.R.I.B.A.

The Archbishop of Canterbury then pronounced the benediction, and Sir W. Jenner having had the honour of kissing Her Majesty's hand, the Royal party retired.

Seldom, if ever, has her Majesty's appearance in public been more auspicious, and rarely has she performed a more gracious act, and one which we are sure will endear her more to the hearts of an appreciative people.

PASTEUR'S METHOD IN HYDROPHOBIA.

MANY of our readers are unacquainted with the method adopted by Pasteur for the prevention of the development of hydrophobia; to meet their requirements we publish the following information. If a piece of spinal cord from a rabid street dog be placed under the dura mater of a rabbit, by trephining, rabies will develop in the rabbit after an average period of incubation of about fifteen days. If the virus from this first rabbit be transmitted to a second, and from the second to a third, and so on by the same method of inoculation, it is soon found that the rabies becomes more and more pronounced, and the period of incubation becomes shorter and shorter. After the transmission through twenty or twenty-five rabbits the period of incubation is eight days, and at this point it remains for a fresh period of twenty-five transmissions. Then at the end of the fiftieth inoculation the incubation period is seven days. These results were found to be perfectly invariable, and the experiments begun in 1882 have been continued ever since. Consequently nothing is more easy than for the operator to have constantly by him during intervals of considerable duration a virus of rabies of perfect purity, and always perfectly identical, or as nearly so as possible. This is the practical point in the method. The spinal cords of these rabbits are "rabid" throughout their extent with a constant degree of virulence. If from one of these cords a certain length be removed with all proper antiseptic precautions and be suspended in dry air, the virulence slowly disappears in the spinal cord until it is extinguished. The time that elapses before extinction varies a little with the thickness of the pieces of cord, but more especially with the temperature of the environment. The lower the temperature, the longer is the virulence preserved. These facts constitute the scientific point in the method. It is interesting also to observe that if the rabid spinal cord be kept in carbonic acid gas in a moist state, its virulence is preserved, at least for many months, without any variation, provided it is kept free from foreign microbic alteration. These facts being understood, the following is the method of rendering a dog refractory to the development of rabies. In a series of flasks, in which the air is kept dry by means of fragments of potash deposited on the bottom of the vase, is suspended every day a portion of a rabid cord fresh from a rabbit dead of rabies—of rabies developed after seven days' period of incubation. Every day a syringeful of sterilised bouillon is injected under the skin of the dog—of bouillon which has been mixed with a small fragment of one of the spinal cords undergoing desiccation, a cord being commenced with which is not in a too virulent state, and therefore one which has been suspended a few days before being used. Previous experiments of course enable these details to be ascertained. The following days still more recent cords are used, separated by an interval of two days, until a time is reached when a very virulent cord is used—one that has been placed only a day or two in the flask of dry air. The dog is then completely protected. "You may then inoculate it with the most powerful virus,

Digitized by Google

either under the skin or, by trephining, on the surface of the brain without its ever getting rabid." By the application of this method Pasteur was able to obtain fifty dogs of all ages and all varieties perfectly refractory to rabies, without a single failure, when unexpectedly there presented themselves at his laboratory on Monday, July 6th, 1885, three individuals from Alsace—Theodore Vone, Joseph Meister, and his mother. At Pasteur's invitation M. Vulpian and M. Grancher paid a visit to the boy Joseph Meister, on whom they found fourteen wounds that had been inflicted by a dog which was regarded as incontestably rabid. The life of Joseph Meister was despaired of, and so it was agreed that he should be made the subject of an experiment similar to those by which Pasteur's dogs were rendered refractory to the virus of rabies. On July 6th, at 8 P.M., sixty hours after the infliction of the bites by the rabid dog, in the presence of MM. Vulpian and Grancher, under a fold of skin of the right hypochondrium M. Pasteur inoculated half a syringeful (Pravaz) of bouillon containing a fragment of a spinal cord of a rabbit, dead on June 21st, and preserved in a flask of dry air, consequently a cord that had had its virulence diminished by fourteen days' subjection to the necessary influences. The following days fresh inoculations were made, always in the hypochondriac regions:—

July	7th, at	9 A.M.,	half a syringeful	of a cord kept	14 days
"	7th "	6 P.M.	"	" 12	"
"	8th "	9 A.M.	"	" 11	"
"	8th "	6 P.M.	"	" 9	"
"	9th "	11 A.M.	"	" 8	"
"	10th "	"	"	" 7	"
"	11th "	"	"	" 6	"
"	12th "	"	"	" 5	"
"	13th "	"	"	" 4	"
"	14th "	"	"	" 3	"
"	15th "	"	"	" 2	"
"	16th "	"	"	" 1	"

Corresponding experiments were made on rabbits by trephining so as to gauge accurately the degree of virulence of the cords used. It appeared that the cords used on July 6th, 7th, 8th, 9th and 10th were not virulent, for the rabbits inoculated with them remained free from rabies; but the cords of the 11th, 12th, 14th, 15th and 16th were all virulent and increasingly so, the rabies in the rabbits appearing after a period of seven days' incubation with the cords used on the 15th and 16th. When the condition of immunity is attained the virulent virus may be inoculated and in any quantity without any result.

MORTALITY AND VITAL STATISTICS OF THE UNITED STATES.

THE Census Office of the United States has recently issued the eleventh volume of the Report upon the Census of the United States in 1880. It is a quarto volume of nearly 800 pages, constituting Part I. of a special report on the Mortality and Vital Statistics of the United States in 1880, by Dr. John S. Billings. The United States "has no system of registration of vital statistics such as is relied upon by all other civilised nations," and in default of such a system attempts have been made at each of the last five national censuses to collect, through the agency of the enumerators, data with regard to the births and deaths that occurred during the year preceding the date of each census. Such attempts have been made in Ireland and in other countries prior to the establishment of civil registration. The result of such attempts has invariably been to prove the impossibility of collecting complete or trustworthy data by such a method. Dr. Billings freely admits that "the experience of the United States census furnishes no exception to this rule." It is acknowledged that the enumerators do not ascertain and record more than from 60 to 70 per cent. of the actual number of deaths. With such a preliminary admission as to the nature of the facts dealt with, it may well be doubted whether the elaboration of the bulky volume of tables under notice can be statistically justified. Dr. Billings' introductory remarks, however, which occupy nearly forty pages of the volume, call for notice, and are valuable for the results he has been able to deduce from these imperfect census data bearing upon the comparative healthiness of the United States, and the relative mortality from different forms of disease in different parts of the States. In the concluding paragraph of his introductory and explanatory remarks Dr. Billings says:—"As a general rule, it may be said that the figures given in these volumes are more valuable for suggesting inquiries than for answering them, yet the more I compare them with those of other countries the more I have become satisfied that they are valuable for both purposes if properly used."

The deaths recorded and tabulated for the year of observation preceding each of the last three censuses were equal to a death-rate of 12·54 per 1000 in 1860, 12·77 in 1870, and to 15·09 in 1880. This apparent increase in the death-rate in 1880 is attributed to the success of efforts made in the last census to obtain more complete returns of the deaths than had been the case at the two preceding enumerations.

In order to measure the extent of deficiency in the number of deaths returned by the enumerators at the last census, their returns for the State of Massachusetts (excluding the city of Boston), and for the whole State of New Jersey, were compared with the records furnished from the State registration offices, the total deficiency in which is considered not to exceed 2 per cent. The result of this comparison is to show that the deficiency in the enumerators' returns was 26·6 per cent. in Massachusetts (excluding Boston), and 36·5 per cent. in New Jersey. "The deficiency was greatest among the deaths of infants, of females, and of foreigners, and increases in a tolerably uniform ratio for each month of the year, going backward in time from the date of the census, and was greatest in the thinly settled sections of the country."

With a view to correct this important deficiency in the number of deaths reported by the enumerators, a register form was sent early in the census year (which ended on May 31st, 1880), with a stamped envelope for its return at the end of the year, to everyone in the United States who was reported by his or her postmaster to be a physician, or to be addressed as such. It was requested that the particulars of all deaths occurring during the year under observation within the knowledge of the medical practitioner might be entered in these registers before they were returned. The number of these registers sent out was 70,299, of which only 25,809, or 37 per cent., were returned. The registers' report returned to the census office contained records of 166,896 deaths, of which 61,020, or 36·6 per cent., were found not to have been reported by the enumerators. Even after the correction of the enumerators' returns for Massachusetts and New Jersey by the addition of the cases obtained from the physicians' registers, the new numbers, compared with the numbers furnished by the State registration offices, still showed a deficiency of 13·3 per cent. for Massachusetts, and of 20·1 per cent. for New Jersey. Dr. Billings assumes that after the addition of the deaths proved by the physicians' registers that came to hand to have been omitted, the returns of the enumerators were "still deficient as much as 30 per cent.," which is believed to be the maximum. The result of this rough estimate is stated to be to raise the average annual mortality for the whole country from 15·09, as shown by the uncorrected enumerators' returns, to 18·08 per 1000. It may be noted, however, that if the uncorrected rate (15·09) be raised by 30 per cent., the corrected rate would be 19·62. Dr. Billings on this point concludes that "it seems safe to assume that the death-rate was not less than 17 nor more than 19 per 1000 of the living population, and I shall assume the mean of these—viz., 18 per 1000—as the mortality rate of the United States during the census year."

The grounds upon which Dr. Billings concludes that the maximum deficiency of the corrected death returns is 30 per cent. should be referred to. The recorded mortality during the census year in thirty-one American cities in which the registration records of death is "presumed to be fairly accurate" gave a death-rate of 22·28 per 1000; and as the mortality of such cities is "usually between 4 and 5 per 1000 greater than the average mortality of a large country, including cities, towns, and rural districts," this is said to increase the probability that the rate in the whole of the United States is not far from 18 per 1000. This argument involves so much assumption that it is of doubtful value. Its validity mainly depends upon the accuracy of the presumption that the death records of these thirty-one cities are "fairly accurate." This may be doubted when it is considered that the death-rate of females in Cincinnati is stated

Digitized by Google

to be 18·97, in St. Louis 18·23, in San Francisco 17·02, and in Newark 16·49. A further ground for the belief that the deficiency of recorded deaths in the United States did not exceed 30 per cent. is that the deaths of infants under one year in Massachusetts during the census year were equal to 17·05 per 100 births; "if this be taken," says Dr. Billings, "as the true average proportion for the United States, the deficiency in the number of deaths of children under one year would be a little over 34 per cent.," and as the deficiency at this age is known to be greater than at subsequent ages, it is assumed that the total deficiency cannot have been much more or less than 30 per cent., at which Dr. Billings places it. With reference to this line of argument, it is worth pointing out that the recorded facts for the United States show a rate of infant mortality of only 11·10 per cent. of the births, against the 17·05 shown in Massachusetts, and that the value of the comparison depends in great measure upon the approximate accuracy of the record of deaths of infants in the latter State.

Full consideration, therefore, of the various elements of doubt that envelop all the bases of facts upon which Dr. Billings has had to deal, and upon which he has attempted to construct trustworthy mortality statistics, makes it exceedingly difficult to accept his final conclusion that "it will be *seen* that the death-rate in the United States compares favourably with that of all other civilised countries." It may readily be admitted that "since poverty and overcrowding are the chief causes of excessive mortality, and in the United States there is a more general and equable distribution of the means of supporting life, including especially a food-supply of good quality, and more room than in European countries," the death-rate might be expected to be lower than in most of the countries of the old world. We cannot, however, accept Dr. Billings' figures and deductions as affording satisfactory evidence that the death-rate in the United States in the census for 1879–80 did not exceed 18·0 per 1000, although they abundantly prove that any conclusions based upon the recorded deaths, except in a very small section of the States, including mainly a certain number of registration cities, are entirely untrustworthy.

It is matter for international regret that in such essential departments of vital statistics as the registration of births and deaths the United States should be so far behind most other civilised countries. Until, however, some tolerably uniform system for such registration be adopted throughout the States, we much doubt whether, either from a public health or a statistical point of view, the comparison of American and European mortality statistics can yield any useful result.

IRISH MEDICAL SCHOOLS AND GRADUATES' ASSOCIATION.

THE ninth annual meeting of the above Association was held on the 17th inst. (St. Patrick's Day), at 49, Berners-street, the President, Dr. H. Macnaughton Jones, F.R.C.S.I., in the chair. There was a large attendance of members. The report, which extended over a period of less than eight months, was of a most satisfactory character. The number of members had increased since July 29th last—when the eighth annual meeting was held at Cardiff—from 272 to 355. Two members had died during that period—viz., Drs. F. Helen Prideaux and J. J. Jennett. There had been no resignations. The Council hoped that, their senior Vice-President, Dr. Balthazar Foster, being now an M.P., there would be no delay in getting power for the King and Queen's College of Physicians to register its membership and the Royal University of Ireland its degree of M.A.O. No steps had yet been taken to secure rooms for the Association in London, the Council thinking it better to wait till the numbers on the roll had reached at least 500. The balance in the hands of the treasurer was declared to be over £40. On the motion of Professor G. F. Yeo, M.D., Dr. Jones was re-elected President in consideration of his services in connexion with the reorganisation and rapid development of the Association, and also because of the curtailment by the new constitution of the period during which he had held office. Brigade Surgeon W. Alexander, M.D., and W. H. White were elected to the two vacancies on the Council. Dr. James Thompson was re-elected Hon. Treasurer.

The annual dinner took place the same evening at the Holborn Restaurant. Ninety-two members and their friends (the latter including several ladies) sat down. The chair was occupied by the President, who was supported by Sir Spencer Wells, Bart., F.R.S., Sir Joseph Fayrer, K.C.S.I. (Hon. Physician to the Queen), Professor Humphry, F.R.S. (Cambridge), and other guests of the Association. Among the members present were Sir William Mac Cormac (Vice-President), Professor Gerald F. Yeo (Chairman of Council), Brigade Surgeons T. Wright and W. Alexander, Staff Surgeon O'Sullivan, R.N., Dr. S. J. Flood, A.M.S., Dr. Carte (Coldstream Guards), Dr. James Thompson (Hon. Treasurer), and Drs. Daniell and Stewart (Hon. Secretaries).

WILLS OF MEDICAL MEN.

THE Irish Probate, sealed at Dublin, of the will and codicil or scheme of Barnewall Peter White, M.D., late of St. Columbs, co. Londonderry, who died on December 3rd last, granted to Mr. Michael King, one of the surviving executors, was resealed in London on the 2nd inst., the aggregate value of the personal estate in England and Ireland amounting to upwards of £31,000. The testator gives annuities to his wife and his two sisters charged on his Tamlaght estate, in the county of Londonderry; and there are a few other bequests. The Tamlaght estate he devises to the use of his half-brother, Richard White, for life, with remainder to his son, Thomas Earle White, for life, with remainder to his first born and other sons successively according to seniority in tail male. Certain plate, furniture, books, and effects are made heirlooms to go with the estate. His waterside estate in the city of Londonderry, he settles on his half-brother, Thomas White, for life, then on his son, and in default of a son on the said Thomas Earle White. He appoints as his residuary legatee the person who shall succeed to the Tamlaght estate. Should the remainders to the said estates fail, the testator gives them to the Superioress-General of the Sisters of Charity, Dublin, to found an asylum for the families of professional and commercial men, small proprietors and agriculturists afflicted with insanity, whose relatives have insufficient means to pay the usual pension for them in private asylums.

The will of Murdoch Kelburne King, M.D., late of Kingston-upon-Hull, who died on January 2nd last, was proved at the York District Registry on the 22nd ult. by Mrs. Mary King, the widow, the executrix, the value of the personal estate amounting to over £14,000. The testator bequeaths the marble bust of himself to his wife for life, and then to the General Infirmary, Hull; the oil painting of himself, in his mayor's robes, to his wife for life, and then to the Mayor, Aldermen and Burgesses of the Borough of Kingston-upon-Hull in their corporate capacity, and a few other legacies. The residue of his property he leaves as his wife shall appoint.

The will and codicil of Gavin Milroy, M.D., formerly of 30, Fitzroy-square, late of 21, Church-road, Richmond, Surrey, who died on January 11th last, were proved on January 23rd by Mr. Edward Hawes and George Blundell Longstaff, M.B., the executors, the value of the personal estate amounting to over £10,000. The testator bequeaths £1000 each to the National Refuges for Homeless and Destitute Children, and the Asylum for Idiots, Earlswood; £100 each to the British Medical Benevolent Fund and the Medical Missionary Society of Edinburgh; £1743, being the amount received by him in 1872 from the Colonial Office as remuneration for his tour to the West Indies, and a further sum from his estate to make up £2000 in all, to the President and Council of the Royal College of Physicians, to found and continue a yearly lectureship of three lectures on State Medicine and Public Hygiene; the silver cup presented to him by the College for acting as honorary secretary of the Leprosy Committee, and certain papers and books, to the said College; and many other legacies. The residue of his property he leaves to some nieces, the wife of a nephew, and the infant son of a deceased niece.

The will of Edward Christopher Holland, M.D., late of 15, Catherine-place, Bath, who died on January 5th last, was proved on the 10th inst. by Mrs. Anna Holland, the widow, and Mrs. Eliza Henrietta Hartnell, the daughter, the executrixes, the value of the personal estate exceeding

Digitized by Google

£4000. The only legatees under the will are testator's wife and said daughter.

The will of Joseph Wyatt Crane, M.D., late of Leicester, who died on September 30th last, was proved at the Leicester District Registry on the 19th ult., by Charles Albert Crane, M.D., and Alfred Wyatt Crane, the sons, two of the surviving executors, the value of the personal estate being under £2000. The only legatees under the will are testator's children and his granddaughter, Ethel Crane.

The will and codicil of Frederic Gilder Julius, M.D., late of 4, Portland-terrace, Richmond, who died on January 4th last, were proved on the 8th ult. by Mr. Arthur Onslow Julius, the son, and Mr. William Adolphus Frederick Bateman, the executors, the value of the personal estate exceeding £6000. The testator gives legacies to his sons, the Ven. Archdeacon Julius and Arthur Onslow Julius, and to his daughters, Mrs. Annie Bateman and Miss Mary Caroline Julius; and the residue of his property to all his children in equal shares.

The will of John McGrigor Augustus Thomas Croft, M.D., M.R.C.P., late of 15, Abbey-road, St. John's Wood, who died on Jan. 1st last, was proved on the 22nd ult., by Mr. Harry Smith Styan and Mr. William Henry Biss, the executors, the value of the personal estate amounting to over £2000. The testator leaves all his property, real and personal, to his son, John Bonham Croft.

The following legacies have recently been left to hospitals and other medical institutions:—Mr. George Redford, of Portland-street, Southport, Lancashire, the residue of his real and personal estate to the Southport Infirmary, the Oldham Infirmary, and the Southport Convalescent Hospital, in equal shares.—Mr. William Beale, of Manor House, Stoke Newington, 100 guineas to the Stoke Newington Dispensary, and 50 guineas to the Invalid Asylum at Stoke Newington.—Mrs. Jemima Steuart Barclay, of 1, Gordon Villas, Snells-park, Edmonton, £200 each to the Tottenham Hospital, near High-cross, and the Tottenham and Edmonton General Dispensary, Lower Edmonton; and £100 each to the British Home for Incurables, Clapham, the City of London Hospital for Diseases of the Chest, Victoria-park, the National Hospital for the Paralysed and Epileptic, Queen's-square, Bloomsbury, and the Royal Hospital for Incurables, Putney-heath.—Miss Hannah Domager, of 11, St. James's-square, Bath, £200 each to the Bath Royal United Hospital and the Bath Mineral Water Hospital.—Miss Henrietta Hannah Bult, of 1, Houghton-place, Ampthill-square, £30 each to the Royal Hospital for Incurables, West-hill, Putney, the Royal Free Hospital, Gray's-inn-road, the North London Consumption Hospital, Hampstead, and the National Hospital for the Paralysed and Epileptic, Queen's-square, Bloomsbury.—Mr. James Dorman, of Sandwich, Kent, £100 towards the repairs of the chapel of St. Bartholomew's Hospital, Sandwich, and £15 to the Kent and Canterbury Hospital.—Mr. Richard Towne, of 8, Ormonde-terrace, Regent's-park, £1000 to the National Orthopædic Hospital, Bolsover-street; £300 to the Hospital for Incurables; £200 each to the Cancer Hospital, Brompton, the Hospital for Paralysed and Epileptic, Albert-road, Regent's-park, and the North London Consumption Hospital, Hampstead; and £100 to the Hospital for Sick Children.—Mr. Alexander Bell, of Park-hill, Upper Tooting, £50 to the Hospital for Paralysis and Epilepsy.—Mrs. Mary Gatley Litler, of Wallerscote, near Leamington, Warwickshire, £1000 each to the National Hospital for the Paralysed and Epileptic, Queen's-square, Bloomsbury, and the Royal Hospital for Incurables, West-hill, Putney-heath; £500 to the Warneford Hospital, Leamington; £300 to the British Home for Incurables, Clapham; and £200 to the Convalescent Home, Kenilworth.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6004 births and 5101 deaths were registered during the week ending March 20th. The annual death-rate in these towns, which had steadily increased in the seven preceding weeks from 22·1 to 28·0, further rose last week to 29·3, and exceeded the rate recorded in these towns in any week since February, 1882. During the first eleven weeks of the current quarter the death-rate in these towns averaged 24·4 per 1000, and exceeded by 0·2 the mean rate in the corresponding periods of the ten years 1876–85. The lowest rates in these towns last week were 18·7 in Norwich, 20·9 in Leeds, 21·0 in Bristol, and 21·3 in Leicester. The rates in the other towns ranged upwards to 35·7 in Manchester, 36·0 in Liverpool, 39·2 in Bolton, and 39·6 in Blackburn. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 384, 403, and 430 in the previous three weeks, were 427 last week; they included 195 from whooping-cough, 103 from measles, 44 from diarrhœa, 32 from scarlet fever, 32 from "fever" (principally enteric), 20 from diphtheria, and 1 from small-pox. No death from any of these zymotic diseases was recorded last week in Sunderland, Norwich, or Huddersfield; whereas they caused the highest death-rates in Brighton, Portsmouth, Bolton, and Blackburn. Whooping-cough caused the highest death-rates in Bolton, Portsmouth, and Brighton; measles in Birmingham, Portsmouth, Bolton, and Blackburn; and scarlet fever in Leeds. The 20 deaths from diphtheria in the twenty-eight towns included 14 in London and 2 in Birmingham. Small-pox caused 1 death in Blackburn, and not one in London or in any of the twenty-six other large English towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 7 on each of the preceding two Saturdays, was again 7 at the end of last week; 2 new cases were admitted to these hospitals during the week, against 0 and 1 in the previous two weeks. The Highgate Small-pox Hospital contained 4 patients on Saturday last, one case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had increased in the preceding eight weeks from 477 to 855, further rose last week to 917, and exceeded the corrected weekly average by 436. The causes of 137, or 2·7 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth and Derby; and the largest proportions of uncertified deaths were registered in Halifax, Plymouth Bolton, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased from 22·3 to 27·5 per 1000 in the preceding four weeks, further rose to 27·9 in the week ending March 20th, but was 1·4 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 17·8 and 19·4 in Leith and Dundee, to 33·0 in Paisley, 33·4 in Greenock, and 33·9 in Glasgow. The 690 deaths in the eight towns showed a further increase of 12 upon the numbers returned in recent weeks, and included 14 which were referred to whooping-cough, 11 to diarrhœa, 10 to measles, 6 to "fever" (typhus, enteric, or simple), 1 to diphtheria, and not one to small-pox; in all, 46 deaths resulted from these principal zymotic diseases, against 43 and 51 in the preceding two weeks. These 46 deaths were equal to an annual rate of 1·9 per 1000, which was 0·5 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 19 and 20 in the previous two weeks, declined last week to 14, of which 13 occurred in Glasgow. The 11 deaths attributed to diarrhœa corresponded with the number in the previous week, and included 4 in Glasgow and 3 in Edinburgh. The 10 deaths from measles showed a further increase upon the numbers in recent weeks, and included 8 in Edinburgh and 2 in Leith. The deaths referred to "fever," which had been 7 and 4 in the previous two weeks, were 6 last week, of which 2 occurred in Glasgow and 2 in Greenock. Three of the 4 fatal cases of scarlet fever were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had steadily increased in the preceding six weeks from 135 to 191, further rose last week to 204, and exceeded the number in the corresponding week of last year by no fewer than 80. The causes of 85, or more than 12 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 30·1 and 38·3 per 1000 in the preceding two weeks, further rose to 40·5 in the week ending March 20th. During the first eleven weeks of the current quarter the death-rate in the city averaged no less than 33·4 per

Digitized by Google

1000; the mean rate during the same period did not exceed 24·9 in London and 19·6 in Edinburgh. The 274 deaths in Dublin last week showed a further increase of 15 upon the number returned in the previous week, and included 13 which were referred to the principal zymotic diseases, against 15 and 19 in the previous two weeks; 6 resulted from whooping-cough, 6 from "fever" 1 from diarrhœa, and not one either from small-pox, measles, scarlet fever, or diphtheria. These 13 deaths were equal to an annual rate of 1·9 per 1000; the rates from the same diseases being 2·7 in London and 2·9 in Edinburgh. The fatal cases of whooping-cough, which had been 18, 10, and 11 in the preceding three weeks, further declined last week to 6. The 6 deaths referred to "fever," on the other hand, corresponded with the number in the previous week. Eight inquest cases and 6 deaths from violence were registered; and 84, or considerably more than a quarter of the deaths, were recorded in public institutions. The deaths of infants and of elderly persons showed a further increase upon recent weekly numbers. The causes of 45, or 16 per cent., of the deaths registered during the week were not certified.

"Audi alteram partem."

CYCLIC ALBUMINURIA.

To the Editor of THE LANCET.

SIR,—I consider Dr. Saundby does not render himself justice in saying that no one has remembered his communication on albuminuria published in the *British Medical Journal* in June, 1880. I for one am familiar with what he has written, and even referred to it only a few weeks ago. The observations to which he has directed attention are almost identical in nature with some I conducted on two cases of Bright's disease eighteen years previously. They were brought forward in my Gulstonian Lectures delivered in 1862 and published in THE LANCET for 1863 (vol. i., p. 575).

Dr. Saundby contends that I am wrong if I assert that the diurnal variation to which I have drawn attention is absent in Bright's disease and present only in my cases, and he speaks of my having classified the cases as "cyclic" on the ground that the maximum amount of albumen of the twenty-four hours is found during the after-breakfast period. This is not, however, a correct way of putting it. The term "maximum" is out of place. What is observed is the presence of albumen for a certain period only, the urine during the remainder of the twenty-four hours being entirely free from albumen, instead of, as in ordinary Bright's disease, albumen being continuously present. This constitutes an important difference. I am quite prepared to consider that in Bright's disease there may be causes, apart from the renal conditions, to determine a fluctuation in the amount of albumen; indeed, in the lectures to which I have referred I expressed the opinion that it might be increased by food. Curiously enough, Dr. Saundby's table, if read by the amount of albumen voided per hour, stands in a striking manner diametrically opposed to what he has argued for. It is true that the percentage of albumen in the urine passed between 5 A.M. and 1 P.M. is higher than at other periods, but with this the urine is relatively considerably less in amount; and if the calculation be made so as to represent the amount of albumen eliminated per hour, it comes out in a marked manner less than at any other time, and otherwise the quantities present an irregularly fluctuating character.

I am, Sir, your obedient servant,

Grosvenor-street, March 24th, 1886. F. W. PAVY.

TREATMENT OF CHRONIC INVERSION OF THE UTERUS.

To the Editor of THE LANCET.

SIR,—Dr. Neale's letter in THE LANCET of March 13th is calculated to lead to a misconception of the point for which I contend—namely, that, as far as I yet know, I am the first person to have practised the operation for dividing the cervix uteri to facilitate reduction of chronic inversion of the uterus. In reply to this claim Dr. Neale again quotes Dr. Pratt as writing in March, 1868: "This mode of treatment is not new, although not mentioned by Murphy, &c..... but Dr. Wasseige of Liege says that it is the only legitimate, as it is the most effective, plan." "This," Dr. Neale says, "I think proves that the operation must have had an established reputation abroad before 1868, the date of Dr. Barnes' first operation."

This inference of Dr. Neale's is a glaring *non sequitur*. To help to clear up the question I wrote to Dr. Wasseige, asking him if he had ever performed this operation. The distinguished rector of the University of Liège refers me to his "Opérations Obstétricales," p. 429, for the following: "Lorsqu'on ne peut réduire par les moyens indiqués plus haut, et que le col est rétracté, le Docteur Aran a proposé le débridement multiple du col. Cette opération n'offre pas de grands dangers, et peut donner de bons résultats." The Professor in his letter to me (dated March 17th, 1886) goes on to say: "Pour mon compte je n'ai aucune expérience personelle; je n'ai jamais vu qu'un seul cas d'inversion ancienne, et *cela à une époque où l'on ne tentait aucune opération sérieuse, c'est-à-dire en 1862 ou 1863.*"

From this it will be seen that Dr. Wasseige cannot be held to have referred to the operation as one that had been practised. I myself quoted Aran, and pointed out that he did not describe the operation as having been done by himself or by anyone else.

If Gibbon's aphorism, "He alone discovers who proves," be true, Dr. Arbuckle was not wrong in describing the proceeding as "Barnes' operation."

I am sure Dr. Neale will now "digest" my claim to have been the first to demonstrate by practice the value of the proposal to facilitate reduction of chronic inversion of the uterus by incision of the constricting neck in aid of sustained elastic pressure.

P.S.—The recent news of the sad death of Professor Courty caused me to examine his work on the Diseases of the Uterus published in 1872. The lamented author describes the operation of incising the neck of the uterus as a means of enabling rapid reduction to be made by taxis. He calls it his method, and says he has practised it with success, the subject soon becoming pregnant. He does not specify the date of his case. Possibly it was earlier than my first case in 1868. But his account clearly proves that it was not in 1872 even one of established reputation. He does not refer to my memoir of 1868. And his proceeding differs from mine in that he makes incision the preliminary to forcible taxis, whereas I make it preliminary to sustained elastic pressure.

I am, Sir, yours truly,

March 20th, 1886. ROBERT BARNES.

MANCHESTER.

(*From our own Correspondent.*)

SMALL-POX AND SCARLATINA.

THE neighbouring township of Hyde is passing through a smart outbreak of small-pox, and finds itself sadly wanting in the necessary accommodation for isolating the sufferers. Fortunately for the town, most of the patients have been received into the fever hospitals at Stockport and Monsall, though the latter institution is situate some eight or nine miles from the homes of the patients. It is by no means satisfactory that Manchester, which is at present free from this disease, should thus have brought within its boundaries a number of cases simply because of the neglect of other health authorities to make proper provision for themselves. In the adjoining township of Crumpsall quite an epidemic of scarlatina has lately prevailed. The Local Board of this district, after communicating with the Local Government Board, have decided to pay a fee of 2*s.* 6*d.* for certificates furnished by medical men of the existence of infectious disease, though apparently no steps are to be taken to render the furnishing of these compulsory.

ASSOCIATESHIP OF OWENS COLLEGE.

A very interesting report upon the Associateship of Owens College has lately been published by the principal. He traces its history from the foundation in 1859 to the present time, during which period this distinction has been conferred upon 250 students. The changes which have been made in the regulations for its attainment have been uniformly in the direction of increased stringency, notwithstanding which

Digitized by Google

the numbers have been in much greater proportion during the past few years, no less than eighty having been elected during the past three years. At present the necessary qualifications are three years' *bonâ-fide* study in the College, and the obtaining either a university degree or the membership of the Royal College of Physicians or fellowship of the Royal College of Surgeons. Of the associates elected in the last three years, forty-one out of the eighty were graduates in arts, thus equalling the number of associates in medicine and science added together, showing that equal activity is displayed in the faculty of arts as of science.

VOLUNTEER WORK.

A meeting of medical men and students interested in the work of the Volunteers, presided over by Professor Lund, was held last week at Owens College to hear an address by Surgeon-Major Evatt on the desirability of forming a medical staff corps for the district on the lines carried out in the metropolis. Some of the officers and surgeons of the corps present were apprehensive that the connexion of the present regimental surgeons with their respective regiments would be interfered with, and as many of these have at the expense of much time and labour given ambulance courses to selected numbers of privates, this fear was allayed by Dr. Evatt pointing out that the status of Volunteer medical officers would in nowise be interfered with.

HORSEFLESH AS HUMAN FOOD.

Periodically we are made uneasy by rumours, or rather insinuations, that the sale of horseflesh as butcher's meat prevails very widely in the city and suburbs, especially amongst the poorer classes. Last year an official inquiry was held at the Town Hall, and at a recent meeting of the Executive Committee of the Manchester and Salford Butchers' Association the matter was again under discussion, though no very strong evidence appears to have been forthcoming as to the truth of the allegations. Surely if the butchers themselves know of such practices, it should not be difficult to put the proper officials on the track of the offenders and bring them to punishment. It is contemplated by the Association to decide upon some definite line of action in conjunction with similar bodies in other parts of the country. There can be no doubt that if horseflesh is sold as beef, it must be horseflesh of a very inferior quality.

HOSPITAL SATURDAY AND SUNDAY.

The Hospital Saturday and Sunday Fund has now reached a total of £7160, and it is not probable that much will be added to this sum. Possibly the fact that adjoining towns and districts have funds of their own may be one cause of the diminution this year, for at the annual meeting of the Bolton Infirmary it was stated that the Hospital Saturday and Sunday contributions had increased this year to £1230, against £1061 for the previous year.

Manchester, March 22nd.

LIVERPOOL.

(From our own Correspondent.)

THE RECENT SEVERE WEATHER AND THE HIGH DEATH-RATE.

THE recent severe weather has, as might have been expected, had its influence on the death-rate, especially of the young and aged. At the last meeting of the Health Committee the medical officer of health reported that the death-rate was equal to 29·5 per 1000 of the estimated population. The deaths of children below five years of age number 113, and of persons above sixty, 67. There were 115 deaths returned as due to diseases of the lungs. In the City Hospital for Infectious Diseases there were fifty-five patients, eleven having been admitted during the week; nine were discharged convalescent, and two cases of small-pox, both unvaccinated, died. In the Liverpool Workhouse there were during the week ending the 11th inst., a total of fifty-six deaths, eleven from bronchitis, and thirteen from phthisis.

INTERMENT IN CITY CHURCHYARDS.

Some of our intra-mural churchyards are still open to interment permissively, it being required that, if a grave is to be opened, there shall be sufficient depth to allow of five feet of earth being left above the coffin which it is proposed to inter. In a recent case this was not so, the last deposited coffin being too near the surface to permit of the above very wholesome requirement being ensured. The sexton had opened the grave without the permission of the medical officer of health, who, on hearing of the proposed burial, promptly interfered and stopped it.

THE LOCK HOSPITAL.

There is at present in Dr. Bernard's male ward an interesting case of skin affection which was admitted a month ago. The whole surface of the body, with the exception of the face and the soles of the feet, was covered by an extensive desquamation. The diagnosis was a matter of some difficulty. The history of the case pointed to a syphilitic origin, but the appearance of the scales, which in some situations were very large and of silvery whiteness, afforded strong presumption that a part of the eruption was of the simple kind. The scales in some parts were fully six inches in diameter, especially those found on the extensor surface of the knee and elbow. On the legs and dorsum of the feet copper-coloured papules were noticed. The palms of the hands presented scaling appearances which were absent on the plantar surface. The conclusion arrived at was that the case was of a mixed variety, which was justified by the treatment adopted. This consisted in applying to the surface a mixture of olive oil and oil of cade, together with mercurial vapour baths. The patient's condition has greatly improved, the desquamation has disappeared, and the eruption is satisfactorily waning.

THE DEPRESSION OF TRADE AND OVERCROWDING.

The prevailing depression of trade is evidenced by the largely increasing practice of subletting houses. Large numbers of families, formerly able to rent small houses, are now reduced to taking rooms in houses let off in tenements. Upwards of 19,000 sublet houses (exclusive of common lodging-houses) are now on the register, and incessant care is exercised by the sanitary staff to minimise the evils of the tendency to overcrowd, and at the same time to avoid harassing the poorer classes by a too strict carrying out of the letter of the law. Yet, with every leaning towards leniency, it becomes necessary to issue summons notices against some forty or fifty tenants in chief every week for permitting excessive overcrowding in their houses.

CHARITY ORGANISATION IN LIVERPOOL.

An old and valued charity, the Central Relief Society, was some years ago reconstructed as the Central Relief and Charitable Organisation Society. By its means a large number of the unemployed are provided with work, and others with food. Great care is taken to relieve distress without encouraging mendicancy or idleness.

Liverpool, March 17th.

EDINBURGH.

(From our own Correspondent.)

THE LORD RECTORSHIP OF THE UNIVERSITY.

THE Rosebery Club, consisting of members of the Students' Liberal Association, has commenced the usual triennial campaign in connexion with the election of a Lord Rector, and has selected as a candidate the Right Hon. Sir Lyon Playfair, till recently the Parliamentary representative of Edinburgh University. There are already two candidates in the field, Lord Iddesleigh and Professor Edward Freeman, the former supported by the Conservative students, the latter by the Independent Party. This really means a division of the Liberal interest, which, if undivided, would carry the election; and experience has shown that in three-cornered elections the Conservatives have an advantage from the absolute discipline they are able to maintain; this gives a solidarity to their vote unattainable by their opponents whose strength is almost hopelessly divided. The election does not take place until November; possibly before that date one of the candidates may retire, but this is a remote possibility, and it is to be feared that the Liberals will not be more successful than at the last election, when an independent candidate caused division in their ranks and made way for Lord Iddesleigh's success.

THE WATER OF LEITH BILL.

A Bill for carrying out sanitary measures for the improvement of the water of Leith, the stream which runs through an important district of this city, is before the

Digitized by Google

House of Lords this week. An influential deputation of Edinburgh citizens has been charged with the duty of lending it all possible support in London. Amongst those acting as general members of the committee are the Lord Provost of Edinburgh, Mr. Clark, and several members of the City Council; whilst Professor Douglas Maclagan and Dr. Littlejohn have joined the deputation, prepared with evidence as specialists on the matter. In Edinburgh there is a strong desire that the Bill may become law, as it is felt to be urgently necessary that some system of purification should be adopted which will obviate the present insanitary condition of the stream, which renders it absolutely dangerous to the part of the city it intersects, as well as making its vicinity extremely unwholesome during the summer months.

PROFESSOR SIR WILLIAM TURNER.

A congratulatory address, on his acceptance of the honour of knighthood, has been presented to Professor Sir W. Turner, F.R.S., by the Executive Committee of the Students' Representative Council, a body which represents the undergraduates in all the faculties in the University. In the address, which is couched in very flattering terms, special notice is taken of the close manner in which Sir W. Turner has been associated with the representation of the University interests, as a member of the Royal Commission on the Medical Acts, and as the University representative upon the General Medical Council. In these and other positions his successful efforts to conserve and further the prosperity of this school are commented on, and thankfully acknowledged. The completion of the splendidly equipped Anatomical Museum, which the Professor has so indefatigably laboured for, is also made the subject of congratulation. The address is expressly stated to be an expression of the feeling of the whole constituency which the Council represents, and is the more flattering from the very large numbers of students, over 3000 in all, whose congratulations and good wishes it incorporates.

THE CITY FEVER HOSPITAL.

At a recent meeting of the Town Council, Dr. Russell, convener of the hospital committee, reported that it had been found difficult to obtain the services of a visiting physician for this institution, there being no salary attached to the post. A difficulty also existed as to what body or official had the legal right to confer the post upon any candidates who may yet be forthcoming. The former point was left unsettled, but the meeting decided to obtain counsel's opinion upon the legal question before proceeding further in the matter. In giving a report of the present state of the hospital, Dr. Russell said that there were just now sixty-nine inmates, that the hospital arrangements are most efficiently carried out, and that the patients express themselves well satisfied with the treatment and care which they receive. There are over thirty children in the wards at present, on whose behalf Dr. Russell appealed to the general public, as the hospital is not provided with either toys or pictures.

ROYAL HOSPITAL FOR SICK CHILDREN.

A vacancy has occurred on the staff of this hospital owing to the resignation of Dr. Dyce Fraser, who held the post of extra-physician in charge of the out-patient department. There are several candidates in the field in connexion with the appointment, which is a very important one, from the fact that this hospital is now largely laid under requisition for teaching purposes, and affords opportunities of clinical instruction in a branch essentially necessary to the completeness of the course of study in the Edinburgh School.

Drs. Berry Hart and A. H. Barbour have been appointed to the posts of Assistant-Physicians to the Royal Infirmary in the Department of Gynæcology.

Edinburgh, March 23rd.

ABERDEEN.

(From our own Correspondent.)

TESTIMONIAL AND FAREWELL DINNER TO DR. SIMPSON.

THE members of the medical profession in Aberdeen have presented Dr. Simpson with a handsome gold watch and chain, as a tangible proof of their appreciation of his services as medical officer of health for the city, and of the pleasant relations that have always existed between them and him in the execution of his duties. The presentation of the testimonial took place on Wednesday, the 17th inst., in the presence of a large number of the profession, in the Aberdeen Medico-Chirurgical Society's Hall. Dr. Struthers, President of the Society, occupied the chair; and Dr. Beveridge, who has done so much for sanitary science in Aberdeen, acted as spokesman for his medical brethren. On the following evening a public dinner was given in the Palace Hotel, and a large number of prominent citizens, as well as the majority of the profession, were present to wish Dr. Simpson god-speed and success in his new sphere of labour. In the unavoidable absence of Lord Provost Matthews, Professor Struthers presided, and Baillie Kinghorn was croupier. Dr. Simpson has always taken a lively interest in physical education, and a year ago he was elected chairman of the Aberdeen Gymnastic and Rowing Club. The members of the Club met on Saturday to bid their chairman good-bye, and at the same time presented him with an excellent dressing-case and desk.

THE DUTIES OF THE MEDICAL OFFICER.

Universal regret is felt at the retrograde step the Town Council have taken in deciding that the medical officer should no longer be head of the sanitary department. The various officials are to be responsible to the Public Health Committee, and not to the medical officer, as was the case during Dr. Simpson's term of office. Till the vacancy has been filled up, Dr. MacGregor will act as medical officer of health for the city.

Aberdeen, March 23rd.

PARIS.

(From our own Correspondent.)

VISIT TO M. PASTEUR'S LABORATORY.

I PAID another visit to M. Pasteur's laboratory on Saturday last, where I saw almost all the same persons that I had met there on the previous Tuesday awaiting their turn for inoculation. Dr. Hime, with his party of seven, were also present, and he informed me that another person, who is said to have been bitten by the same dog, had just arrived from Bradford. The nineteen persons concerning whom M. Pasteur had received a telegram from Berlin, referred to in my letter of last week, have also arrived. They are all Russians, and were bitten on Feb. 28th last by a rabid wolf at Beloi, near Smolensk; they were all severely bitten, and five of them so badly that they had to be conveyed to the Hôtel Dieu to have their wounds attended to, where M. Pasteur inoculated them. The other fourteen are lodged in an hotel near the laboratory, and are under the immediate care of the Russian physician who brought the party over, and who accompanies them each morning to the laboratory. The condition of the five patients at the Hôtel Dieu is considered most serious, not only from the severity of the bites, but more particularly from their situation, being inflicted on the face, which M. Pasteur regards as the most dangerous part. Instead of inoculating as usual once a day, M. Pasteur performs the operation twice daily with these Russians for the same number of days—viz., ten,—as he believes the bite of a wolf to be much more terrible than the bite of a dog, which the Russian physician testifies to by the statement that, according to his experience, of twenty persons bitten by a mad wolf, eighteen succumbed to rabies. At my visit on Saturday I saw a woman who said that she had been bitten by her donkey, which had previously been bitten by a mad dog.

To my letter of last week I may add the following note concerning M. Pasteur's laboratory, which I have since had an opportunity of looking over. The rabbits for experiment, which are of all sizes and colours, are kept in iron cages, divided off in compartments, so that each rabbit has its separate box. After the death of a rabbit from rabies after inoculation it serves as a subject for another, from which M. Pasteur extracts the virus, and which in its turn, after death, also becomes a subject, and so on one after the other. This process was begun three years ago, and has been continued ever since without interruption. The portion of the spinal marrow containing the virus is preserved in bottles, being suspended in the interior from the cork

Digitized by Google

without touching the sides; at the bottom of the bottle are placed some fragments of potash which keep the air within in a dry state. When he is about to inoculate, M. Pasteur withdraws with great care the marrow from the bottle, which he passes rapidly through the flame of a spirit-lamp, already prepared, in order to destroy the germs which might have been deposited on the surface of the marrow. With a pair of scissors, which have also been heated by the flame, he cuts two or three small bits of the marrow of about the length of half a centimetre, which he again cuts up into small fine pieces, and which he drops into a small glass. On the table are placed small glass balloons hermetically closed by the heat of a lamp, and which have been previously filled with sterilised broth. The assistant breaks the point of a balloon, and draws up with his mouth, through a glass tube, a little of the liquid, which he drops into the glass. This broth serves as a vehicle for the rabic marrow. With a glass rod he presses and triturates the marrow in the broth; a sort of emulsion is thus formed, which, when precipitated, leaves a yellowish liquid, with which the inoculations are performed. As stated in my last, these are executed by Dr. Grancher, and the question may be asked why M. Pasteur does not do them himself. In the first place, he would not have time, as he attends to the applicants, whose names he calls out himself, and presents them for the operation. In the next place, not being a medical man, he would be guilty, according to French law, of illegal practice. The applicants are divided into groups, and as the inoculating virus becomes altered in strength daily, the new comers are first inoculated with the weakest virus, and the older ones with the fresh virus. The assistant fills the syringe, which contains a little less than a cubic centimetre, which he hands to Dr. Grancher, who performs the operation as described in my last. I may here observe that the same needle serves for several persons on the same day without undergoing any antiseptic preparation or even being wasted, which rather surprised me, particularly in these days of microbophobia. Dr. Grancher informed me that of every ten applicants for the inoculation eight belonged to the male sex. In a conversation with M. Pasteur, he told me that the subscriptions for the establishment of a suitable place for the carrying out of his method are flowing in from all quarters, and that the amount already far exceeds his expectations. At the last meeting of the Council of Public Hygiene of the department of the Seine the sum of 1300 francs was subscribed for the undertaking. M. Pasteur who was present, thanked the Council for the interest it took in the creation of an institution which is to bear his name, and added that it would find itself thus associated with a work which will perhaps become something more than an institution for anti-rabic inoculation, and which may form a centre for the study of virulent and infectious maladies. M. Pasteur is a man of ordinary size, about sixty years of age, rather thick-set, and somewhat brusque in his manner. About ten years ago he had an attack of apoplexy, which resulted in hemiplegia of the left side, from which, however, he has in a great measure recovered, and he seems not to have lost any of his former energy and intelligence.

One of the Russian patients who was bitten by a mad wolf, and who was sent to the Hôtel Dieu owing to the severity of his wounds, died on Monday at that hospital from hydrophobia, the symptoms of which manifested themselves on the previous Saturday, after the eighth inoculation—that is to say, when, according to M. Pasteur's method, the treatment had not been completed.

Dr. Triboulet died suddenly on Sunday night, the 21st inst. He took his degree in 1853, and was at his death physician to the Trousseau Hospital.

Paris, March 23rd.

THE SERVICES

THE Queen has been pleased to allow Henry Pottinger Keatinge, Surgeon-Major in the Egyptian Army, to accept and wear the insignia of the Fourth Class of the Order of the Osmanieh, which His Highness the Khedive of Egypt, authorised by His Imperial Majesty the Sultan, has been pleased to confer upon him, in recognition of his services whilst actually and entirely employed beyond Her Majesty's dominions in the Egyptian Army.

ADMIRALTY.—Deputy Inspector-General of Hospitals and Fleets Timothæus John Haran has been promoted to the rank of Inspector-General of Hospitals and Fleets in Her Majesty's Fleet. Fleet Surgeon William James Eames has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet.

The following appointments have been made:—Deputy Inspector-General Doyle M. Shaw, C.B., to Malta Hospital; Deputy Inspector-General Adam B. Messer, M.D., to Plymouth Hospital; Surgeon Cyril J. Mansfield, to Haslar Hospital; Surgeon Horace Elliott, to the *Duke of Wellington*, for service at Haslar Hospital; Surgeon Percy Edmund Maitland, to the *Impregnable*, for service in the *Canopus*; Surgeon Matthew Digan, to Haulbowline Hospital; Surgeon George William F. Armstrong, to the *Monarch*; Surgeon Charles Albert Macaulay, to the *Belleisle*; and Surgeon John Nicholas Corbett, to the *Coquette*.

MILITIA MEDICAL STAFF.—Surgeon Alexander Skipton, 9th Brigade, North Irish Division, Royal Artillery, to be Surgeon-Major.

VOLUNTEER MEDICAL STAFF CORPS.—Richard Lake Gent., to be Surgeon.

Obituary.

T. SPENCER COBBOLD, M.D., F.R.S., F.L.S.

WE deeply regret to announce the death of this esteemed and well-known member of the profession, which took place at his residence in Portsdown-road, Maida-hill, on the 20th inst. To many of his friends the news came with a shock of surprise, for it was not widely known that his health had been broken for some months past. The first symptoms of his ailment were manifested by a syncopal attack which occurred after speaking by request at the soirée held at the Middlesex Hospital last summer. It appeared that he was suffering from aortic disease with cardiac hypertrophy, and, notwithstanding cessation of work and enforced quietude, he became subject to anginal attacks and cardiac dyspnœa. He died in one of these paroxysms.

Dr. Cobbold was one of the well-known family of that name in Suffolk. He went to Edinburgh to study medicine, and was a fellow-student and friend of several distinguished men there. He was a devoted pupil of John Goodsir and Edward Forbes. In 1851 he took his M.D. degree, and was, with Charles Murchison, Burdon Sanderson, and four others, a gold medalist of his year. He became subsequently Curator of the Anatomical Museum in the University, and was elected Senior President of the Royal Medical Society in 1851-52, Dr. Dobie of Chester being junior president the same year. He remained for some years in Edinburgh working diligently at comparative anatomy under Goodsir. Subsequently he came to London, and was appointed Lecturer on Botany, Zoology, and Comparative Anatomy at the Middlesex Hospital School. For some time he lectured there on Parasitic Diseases. He was also lecturer at the Veterinary College. He did not practise for some years after settling in London, and about twenty years ago he devoted himself to a limited sphere of work as a consultant in cases of parasitic disease, helminthology being a very special and favourite line of pursuit with him. He was without doubt one of the first British authorities on this subject, and made several original and valuable investigations in it, many of the results of which were from time to time contributed to our columns. He was elected into the Royal Society about 1865. His work was always carefully done, and pursued with persistency and enthusiasm. He was clear and dogmatic as a teacher, and had always the courage of his opinions.

The social side of his character was well marked. He was kind and affectionate in disposition, and thus won and kept many friendships. He was devoted to music, and possessed a remarkable voice, a high pure alto, which none who ever heard it can forget. At the dinner of the Edinburgh Club, which he regularly attended, he was often a contributor to the subsequent musical entertainment. He published several works on the Entozoa, one of which is a classical treatise on the subject. Many foreign scientific societies enrolled him as honorary and corresponding member. He held the Swiney Lectureship on Geology at the British

Digitized by Google

Museum for the allotted term of two years, this post being open only to graduates in medicine of Edinburgh. He never joined the College of Physicians of London, or took any diploma other than that of his degree. All who knew him in any capacity must find cause for lament at his decease at the comparatively early age of fifty-seven. He leaves a wife and several children, having married early in life. It is not too much to affirm that his peculiar place in the profession can hardly be filled up. The study of helminthology is not a very attractive one, and few are found to devote laborious attention to the abstruse and difficult problems involved in it, especially in its etiological and developmental relations. It is still less likely that anyone will take up the subject with a view to attain position as a consultant in so limited a specialty. His success in treatment, after failure on the part of others, appeared to depend on careful method and timing of the dosage of anthelmintics, and he laid great stress on the importance of procuring only good and trustworthy drugs as vermifuges. He had never the manner or habits of a physician, and was perhaps chiefly esteemed as a man of science and a votary of biological studies. He himself did not cultivate practice. Not that he was quite independent of it, but he loved nature more. His love of nature was keen, and he delighted in being face to face with every aspect of it. Amongst his last regrets was this—that he felt unequal to arrange his accumulation of facts for publication, and his greater longing was to live on to see the charms of another spring and summer after the long and bitter winter which so cruelly tried him. He has left us, and has entered now on that fuller life which must bring to him such joys as his busy and contemplative career here so well prepared him for. *Quando ullum inveniemus parem?*

DANIEL ELIAS, M.D.

SOUTHPORT has lately sustained the loss of a highly popular and much respected medical man. Dr. Daniel Elias began his professional career as assistant to the late Dr. Scowcroft, with whom he afterwards entered into partnership. On the death of Dr. Scowcroft he commenced practice on his own account, and became rapidly known and liked in the town. Some years later he took his brother, Dr. Tom Elias, into partnership, and the two brothers enjoyed a very extensive practice—so large, indeed, that it completely occupied the whole of Dr. Elias's time. He acted for many years as honorary medical officer to the infirmary, and was very active in his endeavours to ameliorate the condition of the poor; it was mainly due to him that the Southport Infirmary attained its present efficiency. In all matters concerning the welfare of the town Dr. Elias took an active part, and was esteemed for his business capacities as well as his professional ones. He was most popular with all classes of society, and owed a great portion of his success to his untiring energy and great power of sympathy. His death, at the age of forty-eight, took place on March 1st, from nervous prostration, general debility, and atrophy of the heart. He had been suffering from great weakness for some six months previously, and had in a measure retired from active practice. His funeral was attended by a large number of his professional brethren, as well as by an immense concourse of friends and patients.

MEDICAL NOTES IN PARLIAMENT.

The Lunacy Laws.

ON the 18th inst. the House of Lords went into Committee on the Lunacy Laws Amendment Bill, when, after some discussion, in which the Earl of Selborne, the Lord Chancellor, Viscount Cranbrook, and other peers took part, the Lord Chancellor withdrew all the clauses relating to idiots and imbeciles as distinguished from lunatics; and announced his intention of at once introducing a Bill dealing with idiocy. Numerous amendments having been agreed to, the clauses of a controversial character were postponed.

Burgh Police and Health (Scotland) Bill.

On the 23rd inst. the Earl of Elgin moved the second reading of this Bill.—Lord Balfour of Burleigh said he understood there were points in the Bill which, in the opinion of some critics, were open to grave objection; but those who were best entitled to speak for the inhabitants of the burghs affected by it were perfectly unanimous that some such measure was required. He hoped, however, that an interval of ten days or a fortnight would be given before the committee stage of the Bill was taken, in order that a reasonable time might be afforded for its consideration.—The Earl of Galloway suggested that it would be well if the Government would consider whether the time had not now come when there ought to be established one general police force of an Imperial nature.—The Earl of Elgin having spoken, the Bill was read a second time.

Imbeciles.

The Lord Chancellor presented a Bill to give facilities for the care, education, and training of idiots and imbeciles.

Ventilation of the House of Commons.

In the House of Commons on the 23rd inst., on the motion of Mr. Leveson-Gower, a Select Committee was appointed to inquire into the ventilation of the House, as follows:—Dr. Farquharson, Sir H. Roscoe, Mr. Lyell, Sir G. Hunter Mr. Isaacs, and Mr. R. Power.

Medical News.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a recent meeting of the Board of Examiners the undermentioned was admitted a Fellow of the College:—

Henry Plunket Ermonde-White, Surgeon-Major, A.M.D.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 18th inst.:—

Adie, Alexander James, Leonard-street.
Halsted, Harold Cecil, M.R.C.S., Slindon, Arundel, Sussex.
Lister, Joseph Jackson, M.R.C.S., Wimpole-street.
Pope, Henry Alex. Lepthairia, Donegal, Ireland.
Priestley, Percy, M.R.C.S., Norfolk-street, Sheffield.

ROYAL HOSPITAL, BELFAST.—A portrait of Mr. Lyons, D.L., has been presented to this institution in recognition of his services to the hospital.

ON the 22nd inst. a meeting, presided over by the Lord Mayor, was held at Stratford, to further the formation of a cottage hospital for West Ham.

DOUBLE CATARACT EXTRACTION AT AN ADVANCED AGE.—An old Russian tailor whose age is 101 has just had cataract extraction performed successfully on both eyes.

A HAMBURG merchant has left 450,000 marks (£22,500) for the erection of a sea-bathing infirmary at Cuxhaven at the mouth of the Elbe.

THE Dutch Ministry has undertaken to introduce into the Chamber a measure for preventing the adulteration of food, and especially the sale of artificial butter, the so-called "margarine."

THE Chemical Laboratory of the Liverpool University College was opened on Saturday, when Lord Derby, the president, was expected to be present, but was prevented through indisposition. Sir Lyon Playfair addressed a large and influential company in the lecture hall.

MEDICAL MAGISTRATES.—Professor R. J. Anderson, of the Queen's College, Galway, and Beechill House, co. Down, has been appointed a Justice of the Peace for the latter county. Frederic Orton, M.D., Crouch-end, N., and F. H. Daly, have been appointed Justices of the Peace for the county of Middlesex. Mr. Marshall Weir, M.R.C.S., the medical officer of Dromore Dispensary, has been placed on the Commission of the Peace for the county of Down.

BRISTOL ROYAL INFIRMARY.—At the annual general board meeting of the trustees of this institution on the 23rd inst., it was reported that the total income during the past year had amounted to £16,000, including a legacy of £5000, and that the total expenditure was £12,000. The number of in-patients, as compared with those received during 1884, showed a diminution, which may be accounted for by the fact that during 1885 the triennial cleaning of the house took place, which necessitated the closing in succession of all the wards. The committee desire it to be known that ladies can now be received as probationers, for training as nurses, upon the same system as in the London hospitals.

Digitized by Google

POISON IN CABBAGE-SOUP.—A number of Russian peasants have been poisoned by *kohl*- or cabbage-soup, made from vegetables preserved in vessels which, on examination, proved to be coated internally with a very appreciable quantity of arsenic. The victims were treated with milk, and though for a time they were apparently in great danger, all recovered. No clue has been discovered as to the manner in which the arsenic found its way into the barrel of "*kohl*."

HEALTH EXHIBITION, YORK.—A meeting was held at York on the 17th inst., to consider the arrangements to be made for the Sanitary Congress and Health Exhibition to be held in the city in September next, by the Sanitary Institute of Great Britain. An influential deputation from the institute attended and spoke of the satisfactory results which had followed previous congresses. It was decided that the meetings should commence on September 21st, and that the exhibition shall remain open one month.

THE NOMENCLATURE OF BRAIN DISEASES.—In pursuance of a resolution passed at the Medical Congress on Brain Diseases, held during last summer at Antwerp, by which it was suggested that local conferences should be held to draw up trustworthy international tables of statistics on insanity, a conference of Austro-Hungarian specialists is to be held at Vienna with the object of revising and extending the nomenclature of mental disorders. Invitations to the conference have been issued by four leading medical men of Vienna.

A FRIVOLOUS OBJECTION.—The Paris Civil Tribunal has just decided a case in which Dr. Peyrol, head surgeon at the Hôtel Dieu, claimed 800 francs for extracting a bullet from a young lady who had accidentally shot herself. The claim was disputed on the ground that the plaintiff stated erroneously that the bullet was lodged in the right thigh. The tribunal overruled the plea, believing that it mattered very little whether the bullet was on the right or the left side so long as the patient's sufferings had been relieved, and judgment was consequently given for the plaintiff.

THE LONDON HOSPITAL.—The increased accommodation recently provided for nurses at the London Hospital, Whitechapel-road, E., now enables that institution to supply thoroughly trained nurses to private families. Nurses trained in the busy wards of this large hospital must have exceptional opportunities for gaining experience of a nature likely to render them specially efficient, and it is satisfactory to learn that the constantly increasing demands of the public for skilled home nursing are to be met by fresh efforts to maintain an adequate supply.

THE BLANE MEDALS.—The two gold medals founded by the late Sir Gilbert Blane, Bart., to be conferred, once in two years, on two medical officers of the Royal Navy who shall have delivered into office journals evincing the most distinguished proofs of skill, diligence, humanity and learning in the exercise of their professional duties while in medical charge of ships, have been awarded, by the Director-General of the Medical Department of the Navy, jointly with the Presidents of the Royal Colleges of Physicians and Surgeons, to Fleet-Surgeon Henry Scott Lauder and Surgeon Myles O'Connell McSwiny.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—The annual meeting of the members of this Association was held on the 11th inst. In the eleventh annual report, which was read and adopted, the committee congratulated the members on the increased usefulness of the Association, which continues to render good service to the public and to the profession. There are now thirty-seven members, twenty-seven associates, and four honorary members. Dr. G. H. Gornall (Warrington) was elected President for the year; Dr. W. H. Barr (Bury), Vice-President; Dr. Pettinger, Treasurer; and Mr. Vacher, Honorary Secretary.

A CHILD POISONED BY THE NURSE'S COSMETIC.—A German practitioner being called to see a child of five weeks old who was continually crying and suffering from colic, and whose skin was of a dull bluish tint, was somewhat puzzled as to diagnosis, until looking at the nurse's face, and seeing it of a brilliant white and red tint, he touched the surface, which left a greasy stain on his finger of a cosmetic rich in lead. This poisonous substance the nurse had long been in the habit of using for the purpose of improving her complexion. The cause of the child's colic being removed, and appropriate treatment adopted, a cure was effected in a few days.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BROWNE, DANBY, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the Clunbury and Hopesay District of the Clun Union.

CLAPP, ROBERT, L.R.C.P.Lond., M.R.C.S., has been appointed Senior Assistant Medical Officer to the Devon County Asylum.

COOPER, AUSTIN N., F.R.C.S.I., has been appointed Medical Superintendent to the British Hospital, Buenos Ayres.

CULLIN, RICHARD B., L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Tiverton District of the Tiverton Union.

DODSON, ARTHUR E., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Workhouse, Garratt-lane, of the Wandsworth and Clapham Union.

ERSKINE, ROBERT, M.D., has been appointed Medical Officer for the Camborne District of the Redruth Union.

GOODRIDGE, WILLIAM P. B., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Surgeon-Superintendent in the Queensland Government Emigration Service.

HOARE, WILLIAM, M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Titchfield District of the Fareham Union.

MAGGS, WILLIAM ADOLPHUS, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., L.D.S.Eng., has been appointed Dental Surgeon to the North-West London Hospital, vice F. Newland Pedley, F.R.C.S.Eng., L.D.S., resigned.

MAILE, C. E. DRAYSON, M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Seventh District of the Lexden and Winstree Union.

MORTIMER, JOHN, M.B.Lond., has been appointed Surgeon-Administrator of Anæsthetics to the Dental Hospital of Exeter.

PERRY, F. F., Bengal Medical Service, has been appointed Professor of Surgery and Anatomy to the Lahore Medical School, Punjab.

PLATT, HENRY T., M.B., has been appointed Assistant House-Surgeon to the Preston Royal Infirmary, vice F. P. Maynard, M.B., M.R.C.S., L.R.C.P.Lond., resigned.

PRENDERGAST, J. M., M.D. Royal Univ., M.R.C.P.Lond., M.R.C.S., has been appointed Resident Physician to the Hertford British Hospital, Paris.

ROPER, ARTHUR C., M.R.C.S., has been appointed Surgeon-Administrator of Anæsthetics to the Dental Hospital of Exeter.

TISDALL, JOHN J., L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the South Municipal District of the West Derby Union.

WALKER, LAWRENCE NEWMAN, L.F.P.S. & L.M.Glas., L.S.A.Lond., has been appointed by the Cape Government District Surgeon and Public Vaccinator for Calvinia of the District of Clanwilliam, Western Province, South Africa.

Births, Marriages, and Deaths.

BIRTHS.

HENDERSON.—On the 21st inst., at 6, Hampstead-lane, Highgate, London, the wife of A. Milne Henderson, M.D., of a daughter. Australian papers please copy.

HOLMES.—On the 20th inst., at Priory House, Kew, the wife of Gordon Holmes, M.D., of a son.

LUCAS.—On the 14th inst., at Bury St. Edmunds, the wife of R. H. Lucas, M.R.C.S., of twin boys.

MAXWELL.—On the 23rd inst., at Lasswade, the wife of C. M. Maxwell, M.B., of a son.

MORSE.—On the 16th inst., at Prince of Wales-road, Norwich, the wife of Thomas H. Morse, F.R.C.S.Eng., of a son.

SHORE.—On the 22nd inst., at Hill Side, Crouch-hill, N., the wife of T. W. Shore, M.D., B.Sc., of a daughter (stillborn).

MARRIAGES.

BREMNER—CLIFTON.—On the 17th inst., at Victoria-street Congregational Church, Derby, Alex. T. Bremner, L.R.C.S., L.R.C.P., of Leicester, to Constance Annie, second daughter of Frederick Clifton, of Derby.

HARWOOD—ROBINSON.—On the 18th inst., at St. James's, Pokesdown, Bournemouth, Sweitzer Soutter Harwood, M.D. Univ. of Pennsyl., L.K.Q.C.P. & L.M.Irel., of Gordon House, Pokesdown, to Josepha, widow of John Mundell Robinson, of Edinburgh.

SMART—WATSON.—On the 17th inst., at Ballaneleroch, Stirlingshire, Robert Smart, M.D., of Glasgow, to Mary Anne Matilda, youngest daughter of the late William Leckie Ewing, of Arngomery, and widow of James Francis Watson, of Pitcairns, Perthshire.

DEATHS.

BRONNER.—On the 19th inst., at Manor-row, Bradford, Yorks, Edward Bronner, M.R.C.S., L.S.A.Lond., in his 64th year.

COBBOLD.—On the 20th inst., at Portsdown-road, W., Thomas Spencer Cobbold, M.D., F.R.S., F.L.S., aged 57.

GODFRAY.—On the 12th inst., at St. Helier's, Jersey, C. Le Vesconte Godfray, M.R.C.S., L.M., L.S.A.Lond., Surgeon to the General Hospital and Prison, son of the late Francis Godfray, Esq., Barrister-at-law and Advocate of the Royal Court of Jersey.

PARKIN.—On the 18th inst., at his residence, Codrington-place, Brighton, John Parkin, M.D., F.R.C.S., formerly H.M.'s Medical Inspector for Cholera in the West Indies, in his 86th year.

WILLIAMSON.—On the 16th inst., at Rothesay-road, St. Leonards-on-Sea Francis Williamson, L.R.C.P., M.R.C.S., late Surgeon, Royal Navy, aged 39.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, March 29.

Royal London Ophthalmic Hospital, Moorfields.—Operations, 10.30 A.M., and each day at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1.30 P.M., and each day at the same hour.

St. Mark's Hospital.—Operations, 2 P.M.; Tuesdays, same hour.

Chelsea Hospital for Women.—Operations, 2.30 P.M.; Thursday, 2 P.M.

Hospital for Women, Soho-square.—Operations, 2 P.M., and on Thursday at the same hour.

Metropolitan Free Hospital.—Operations, 2 P.M.

Royal Orthopædic Hospital.—Operations, 2 P.M.

Central London Ophthalmic Hospitals.—Operations, 2 P.M., and each day in the week at the same hour.

Society of Arts.—8 P.M. Mr. Boverton Redwood; Petroleum and its Products (Cantor Lecture).

Medical Society of London.—8.30 P.M. Dr. Day: Irritable Brain and Congestion of the Brain in Children.

Tuesday, March 30.

Guy's Hospital.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

St. Thomas's Hospital.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

Cancer Hospital, Brompton.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

Westminster Hospital.—Operations, 2 P.M.

West London Hospital.—Operations, 2.30 P.M.

Royal Institution of Great Britain.—3 P.M. Prof. Arthur Gamgee: The Function of Circulation.

Royal College of Physicians of London.—5 P.M. Dr. P. W. Latham: On some Points in the Pathology of Rheumatism, Gout, and Diabetes.

Royal Medical and Chirurgical Society.—8.30 P.M. Mr. Barwell: On Supra-pubic Lithotomy.—Mr. Rivington: A case of Vesical Calculus of unusually large size removed by Supra-pubic Cystotomy.—Mr. Jacobson: A case of Supra-pubic Lithotomy.

Wednesday, March 31.

National Orthopædic Hospital.—Operations, 10 A.M.

Middlesex Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.

St. Mary's Hospital.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.

St. Thomas's Hospital.—Operations, 1.30 P.M.; Saturday, same hour.

London Hospital.—Operations, 2 P.M.; Thursday & Saturday, same hour.

Great Northern Central Hospital.—Operations, 2 P.M.

Samaritan Free Hospital for Women and Children.—Operations, 2.30 P.M.

University College Hospital.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

Royal Free Hospital.—Operations, 2 P.M., and on Saturday.

King's College Hospital.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.

Society of Arts.—8 P.M. Dr. T. R. Armitage: Methods for Rendering the Blind Self-supporting.

Thursday, April 1.

St. George's Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital.—Surgical Consultations, 1.30 P.M.

Charing-cross Hospital.—Operations, 2 P.M.

North-West London Hospital.—Operations, 2.30 P.M.

Royal Institution of Great Britain.—3 P.M. Prof. Dewar: Electro-Chemistry.

Royal College of Physicians of London.—5 P.M. Dr. P. W. Latham: On some Points in the Pathology of Rheumatism, Gout, and Diabetes.

Parkes Museum of Hygiene.—8 P.M. Dr. Louis Parkes: London Vestries and the Administration of Sanitary Law in the Metropolis.

Harveian Society of London.—8.30 P.M. On the Treatment of Obscure Forms of Uterine Metrorrhagia.

Friday, April 2.

St. George's Hospital.—Ophthalmic Operations, 1.30 P.M.

Royal South London Ophthalmic Hospital.—Operations, 2 P.M.

West London Medico-Chirurgical Society.—8 P.M. Mr. Percy Dunn: (1) Scirrhus Growth of Breast; (2) Sac and Contents of large Femoral Hernia, with Gangrene of Walls; (3) Stomach from case of Carbolic Acid Poisoning.—Brigade-Surgeon Curran: Photographs of Elephantiasis and Oriental Boil, Native Indian Eye Probes, and Gall-stones.—Mr. R. F. Benham; On Epileptiform Seizures due to Sudden Anæmia of the Brain.—Dr. Campbell Pope: Case of Epileptiform Seizure due to Irregular Cardiac Action.—Dr. G. N. Pitt: On Cardiac Dilatation at Puberty.

Society of Arts.—8 P.M. Mr. James Gibbs: The History of Archæology in India.

Royal Institution of Great Britain.—9 P.M. Mr. Howard Grubb: Telescope Objectives and Mirrors, their Preparation and Testing.

Saturday, April 3.

Middlesex Hospital.—Operations, 2 P.M.

Royal Institution of Great Britain.—3 P.M. Mr. Howard Grubb: The Astronomical Telescope.

Society of Arts.—3 P.M. Prof. George Forbes: Electricity.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

THE POISONS ACT.

THE remarks in our last issue were exemplified last week in Wigan. A shoemaker poisoned himself with bisulphide of carbon, a drug which he was enabled to readily obtain owing to its not being scheduled in the present Poisons Act. Bisulphide of carbon is a substance which is used in the course of trade by shoemakers for making cement, and it was difficult to ascertain in this case the quantity of poison taken, no account of the sale having been kept by the chemist.

M.R.C.S.Eng. & L.S.A.—By the 35th Section of the Medical Act every registered medical practitioner has exemption, if he so desire, from serving all corporate, parochial, and township offices.

DISINFECTION AFTER EPIDEMICS.

To the Editor of THE LANCET.

SIR,—I shall feel greatly obliged to any medical officers of health who will kindly inform me if it is their practice to employ disinfection in houses after all the seven principal diseases of the epidemic class (as contained in the Registrar-General's returns), or what exception they make, if any. I have always hitherto required the employment of disinfection after all these diseases, in accordance with the 22nd Section of the Sanitary Act, 1866; but lately I have met with some opposition to such procedure, as being wholly unnecessary as regards whooping-cough and measles. Your opinion also, Sir, on this matter would be of the greatest value to Your obedient servant,

March 22nd, 1886. A MEDICAL OFFICER OF HEALTH.

*** The usual practice is not to enforce disinfection after measles and whooping-cough.—ED. L.

M.R.C.S.—The War Office has published a manual, to be obtained of Messrs. Clowes and Son, Charing-cross, which contains the information our correspondent probably requires.

Dr. Pitt is thanked.

FUNIS ACCIDENTS.

To the Editor of THE LANCET.

SIR,—The following cases may be deemed of sufficient interest to warrant insertion in your columns.

A short time ago, finding the cord around the neck of a child whose head had just passed the vulva, I proceeded in the usual way to relieve it; just as I had passed it half over the scalp, a sharp pain came on, which snapped it off short at the navel, making the application of the ligature exceedingly difficult. No ill effects followed.

In a case of forceps at the brim, after delivering the head and taking off the forceps under the clothes, the cord was found to be around the neck. After the birth of the body, the cord was found to be half severed and bleeding profusely. I presume a coil of the cord had been caught by the forceps. I am, Sir, yours faithfully,

March, 1886. M.

THE CULMINATION OF QUACKERY.

THIS interesting phenomenon has been reached, according to *El Genio Medico Quirurgico*, at an establishment which has been opened in Barcelona, called the "Medico-cellular Institute," where "every disease without exception" is stated to be treated by "a remedy specific to it, which destroys it and cures it."

Student.—We have no information on the subject beyond what has appeared in our columns.

"NOTES ON THE DIGESTIVE FERMENTS."

To the Editor of THE LANCET.

SIR,—In your issue of Feb. 27th you publish, as the first of a series of "Notes on the Digestive Ferments," a paper by Dr. Murrell on "Pepsin as a Digestive Agent." This paper contains statements which cannot be allowed to pass unnoticed and unchallenged.

After comparing the test for pepsin adopted in the British Pharmacopœia of 1885 with that official in 1867, Dr. Murrell sums up the difference between them is follows:—"In the new Pharmacopœia the time is decreased to one-eighth, while the temperature is raised 32°. This elevation in temperature represents an increase of 16 per cent. in digestive power, so that we lose 87·5 per cent. as regards time and gain 16 per cent. on the temperature, the net result being that our standard is raised 71·5 per cent., for which too much gratitude cannot be shown." Dr. Murrell, then, apparently considers that the solution of the albumen by the pepsin takes place uniformly—that is, that the same amount of albumen is dissolved during equal fractions of the time of duration of the experiment, hence if the time is reduced from four hours to half an hour, or by seven-eighths, the activity of the pepsin must be greater by seven-eighths (87·5 per cent.) to accomplish the same amount of work. The fallacy in this reasoning is equalled only by the inaccuracy of the fundamental proposition upon which it is based. It is a well-known fact that the solution of the albumen does not take place uniformly; indeed, a moment's consideration must have convinced Dr. Murrell to this effect. But, granted for argument's sake that it did, even then to accomplish the same amount of work in one-eighth of the time the activity of the pepsin must be eight times as great, instead of greater by 87·5 per cent. That the elevation of the temperature from 98° to 130° F. represents an increase of 16 per cent. in the activity of the pepsin is to me a new and incomprehensible statement. Authorities on pepsin-testing agree in stating that pepsin is about four times more active at the higher than it is at the lower temperature. But apart from these considerations, the difference in the state of division of the albumen required by the two Pharmacopœias precludes the possibility of any other method of drawing a comparison between the two tests than by actual experiment.

Dr. Murrell decides upon a mode of procedure (that of weighing the residual albumen) which, though it has its advocates, has been generally abandoned, and which leads him into serious manipulative errors. To cut the white of an egg into thin slices instead of pressing it through wire gauze is a decidedly retrograde step, and the manner in which the undissolved albumen is dried and weighed would send a shudder through the frame of an analytical chemist. "Out of thirteen specimens examined," says Dr. Murrell, "only four would have come up to the standard of the new British Pharmacopœia." From any data that may have been ascertained by the test detailed in his paper, Dr. Murrell is not justified in drawing the slightest inference as to the activity of a pepsin when examined by the official method. Whether a sample of pepsin does or does not come up to the standard of the new British Pharmacopœia can be ascertained solely by actual experiment, in which the conditions enjoined by that Pharmacopœia are rigidly adhered to; should it prove deficient, then, and then only, can its condemnation be accepted by pharmacists.

To take for his experiments ten grains of liquid preparations, wines, essences, &c., of which the minimum dose is usually a teaspoonful, is manifestly unfair to the respective manufacturers.

Several other points of minor importance might be alluded to, but for my object the foregoing will suffice. If Dr. Murrell requires a very active pepsin, there is no reason why he should not have it. There is no difficulty in obtaining pepsin of far greater activity than is required by the British Pharmacopœia. I am, Sir, yours truly,

New-street, N.W., March 15th, 1886. HENRY G. GREENISH.

"THE USE OF COCAINE IN OPERATIONS FOR PILES."

To the Editor of THE LANCET.

SIR,—I notice in your issue of the 13th inst. that Dr. Owen Pritchard extols the use of cocaine in operations for piles. Dr. Pritchard describes an operation he has lately performed on one pile. After the application of cocaine he appears to have first crushed the pile, cut it off, and then cauterised it. Dr. Pritchard does not say whether he stretched the sphincter ani muscle. I presume not; for if he had, it probably would not then have been a "painless" operation. I write this to put surgeons on their guard against partial operations on the rectum, either for the cure of prolapsus, fistula, or any other disease, as the operation under these circumstances has to be done over again. I have lately seen several cases of rectal ulcer at the Western Hospital for Fistula, Piles, and other Diseases of the Rectum which had been treated previously. Unfortunately in each case a horseshoe fistula had been overlooked.

I congratulate Dr. Owen Pritchard on the success of his operation; but I still think that cocaine requires to be very cautiously used in rectal surgery. I am, Sir, yours faithfully,

Bennett-street, March 18th, 1886. SAMUEL BENTON.

THE BEST ANTISEPTIC.

ACCORDING to a leader in the *Medical Bulletin*, the best—indeed, the ideal—antiseptic has now been discovered, and is—common salt.

Dr. Hermann Weber.—A short notice would be acceptable.

Dr. Sturges' paper is marked for early insertion.

PROSECUTION UNDER THE INFECTIOUS DISEASES ACT IN SUNDERLAND.

To the Editor of THE LANCET.

SIR,—The following case may be of interest to the profession, as it was made a case of prosecution under the Infectious Diseases Act of the Borough of Sunderland, 1885, where I was last week mulcted, between fine and costs, in a sum of about £4. I shall now lay a faithful account of the case before the profession, leaving them to judge of the justice of it.

On Jan. 6th a message was left for me to call to see a Mrs. L——. On the following day I saw Mrs. L——, and found her in bed. From answers to my questions I gathered that she had been indisposed for more than a month, but able to be out of bed during the greater part of the day. Upon examination, I found a sort of papular eruption over the back and chest, which had, she stated, been present some time. The papules were in general less than the size of a threepenny-piece, slightly raised in the middle, and thinning towards the edges, some of them considerably larger than others, even as large as a halfpenny, and of a brownish colour. The temperature in the axilla was 102°; the tongue was foul and coated. The patient complained of headache, but the mind seemed clear (I may here state that she is of a nervous disposition, and not a strong person at best). The pulse was 90 and weak. I saw her again on the 12th (my assistant saw her on the 11th). The tongue was clean and rather red, as well as the sides of the mouth; temperature, 101°. The patient expressed herself as feeling a little better. My assistant saw her on the 14th, and I again saw her on the 15th. The temperature was 103°; the tongue dry, but clean. She complained of being worse, the head being slighty affected. I suspected fever or blood-poisoning; and as the patient was in a house where there were offices, I resolved to draw the attention of the medical officer of health to the house, although I was by no means satisfied that it was a real case of fever. As the house was close to the health office and a considerable distance from my house, I made out the certificate of notification that night (Jan. 15th), and as the case was very obscure, I took it with me next morning, with the intention of delivering it myself at the health office, and giving an explanation of the case. But while visiting the patient, the husband being at home, and as it was a little out of my way, I gave him the certificate of notification, requesting him to take it to the health office at once, which I believe he did. This method I deemed better and quicker than sending by post, as any explanation that might be required could at once be given, and the necessary disinfectants supplied. The temperature on the 16th was 103°. On the 17th the patient seemed rather better, and the tongue was moist; temperature, 102°.—18th: Temperature, 102°. Tongue moist. The patient had been out of bed, and as she appeared to be improving I did not see her the following day.—20th: Temperature, 101°. She seemed improved, but weak, and complained of headache. On the 24th she was still improving; temperature, 100°. I saw her now and again up till the beginning of February, when I ceased visiting her, as my list during that time was rather heavy, and she seemed so far improved, although by no means strong. It appears that I have reported more cases of infectious disease than any other practitioner in the borough of Sunderland. Your readers may judge of my surprise when I was summoned and mulcted in the sum mentioned, besides the disgrace of having to sit in the police-court from 12 till 2 o'clock. In this case I did my best to bring it under notice, as it was in a house where others were, although I am not yet satisfied as to its infectious nature. In the same room as the patient were sleeping a daughter, eight years of age, and the husband. Neither of them has been affected. The notification was typhoid fever.

I am, Sir, yours obediently,

Sunderland, March, 1886. JOHN RANKINE, M.R.C.P., &c.

A CASE FOR GENERAL SYMPATHY.

To the Editor of THE LANCET.

SIR,—It may be within the remembrance of your readers that in 1883-84 I brought under their notice the distressing case of the wife and two small children of Dr. Cedric H. Harford, B.A., a member of the Medical Department in British Guiana, and that some £500 was collected and invested for their benefit. Dr. Harford's residence in a very unhealthy district (La Retraite) brought on a serious illness, which produced such an effect on his nervous system that he lost his reason and has since died. The interest on the sum raised only produces £35 a year, and Mrs. Harford is striving to maintain herself and her children by giving lessons in singing, for which she is exceptionally well qualified. No doubt people who want their children to sing well would be glad to avail themselves of an opportunity of having them taught from the commencement by one of Signor Randegger's pupils, which Mrs. Harford is. Her terms are 5*s.* a lesson, and all further particulars may be obtained by applying direct to Mrs. Harford, 43, Mimosa-street, Fulham-road, S.W. I desire to thank you once more on Mrs. Harford's behalf and my own for the great assistance you have so kindly rendered in this matter, and I hope that those who have children of a suitable age will give Mrs. Harford a trial in their own interests as well as from feeling of sympathy.

I am, Sir, yours truly,

HENRY C. BURDETT.

The Lodge, Porchester-square, W., March 23rd, 1886.

SECTARIANISM IN HOSPITALS.

THE REV. ARTHUR BRENCHLEY writes: "The Hospitals Association have by no means got to the bottom of this matter yet. Let the Association move the authorities of the various hospitals to issue a strict order that nurses may worship wherever they choose on Sundays. I have known matrons dismiss a nurse for declining to leave off attending the services at All Saints', Margaret-street, and giving leave to Roman Catholic nurses to go out to an early service, refusing the Church of England nurses asking for a similar permission."

Mr. M. H. Miller.—A seven-months' child is much less likely to live than an eight-months' child. There is a fair chance of rearing a child of thirty-two weeks, and every week added to the thirty-two weeks greatly increases the chance.

"COLOUR-BLINDNESS AMONG MEDICAL MEN."

To the Editor of THE LANCET.

SIR,—That there is great diversity, of kind and of degree, in the impressions experienced by different persons in the exercise of the organs of sight, touch, hearing, and taste, is in the knowledge of most medical men. Some of these impressions deviate so largely from a recognised standard as to be serious defects, of which colour blindness and the inability to distinguish acute from grave sounds (as the sharpness or flatness of a musical note compared with a known pitch), to determine the difference between a smooth and a villous surface (as that of satin from that of velvet), and to differentiate the taste of various substances (as of beef and mutton), are some of the most familiar instances. Is the sense of smell exceptionally free from like defects? I think not. In his evidence relating to the case of alleged poisoning by chloroform at Pimlico, as reported in the papers of yesterday, Dr. Stevenson likens the smell of chloral hydrate to that of lemon. Having always felt that the odour of the former was accurately represented by that of the water-melon, and having vainly endeavoured to trace the faintest resemblance in it to that of lemon, I have asked myself whether I am suffering from a defect of the olfactory sense, which, in the absence of a name for it, I venture to call anosphresis (*ανα-οσφρησις*). Perhaps some of your readers, including the eminent analyst referred to, will kindly put me right in this matter, the subject being, as it seems to me, one of great importance in medico-legal investigations.—I remain, Sir, your obedient servant,

G. E. NICHOLAS, M.D.,

March 23rd, 1886. Medical Officer of Health for Wandsworth.

PAINFUL DEFECATION.

PAINFUL defecation due to various causes, including fissure and piles, may, according to a New Orleans physician, Dr. Logan, be relieved at once by applying a few drops of oleate of cocaine to the anus.

Dr. Purcell.—Very soon.

PRACTICE AT THE CAPE.

To the Editor of THE LANCET.

SIR,—In reply to the inquiries of "A Constant Reader" in your last issue (p. 575), I beg to say that after many years' residence in the Cape Colony as a medical man I cannot recommend it at the present time as a field for practice. The Colony is in very low water and crowded with doctors. I know of several well-qualified young men who have been travelling from town to town and find it impossible to earn a livelihood. It was not so formerly. The cause of the change is not far to seek. Many of the better-to-do colonists have of late brought up their sons to medicine, and their example has been followed until the profession has been altogether overdone. These colonists have a great advantage over a stranger: they speak the Dutch language (which is necessary to success), understand local customs, and have family influence. Drugs are easily obtained in Cape Town, price from 100 to 150 per cent. over English prices; bottles 200 per cent. or more, besides inland carriage. A few hundred pounds would be necessary to start with, as money flies while travelling in search of an opening, and while learning the language. I would add, it would be wise to keep a reserve with which to beat a retreat should it be found necessary.

I am, Sir, yours truly,

March 23rd, 1886. CAPE COLONIST.

To the Editor of THE LANCET.

SIR,—If "Constant Reader" will send his address to J. B., 412, Battersea-park-road, S.W., he may get full details of Cape practice and the information he needs.—I am, Sir, yours obediently,

March 23rd, 1886. A COLONIST AND PRACTITIONER.

DERIVATION OF THE WORD "GLAUCOMA."

To the Editor of THE LANCET.

SIR,—I have always seen the word γλαυκος, sea-green, given as the derivation of "glaucoma," and Mr. St. Clair Buxton, who is an ophthalmic surgeon and ought to be an authority, repeats that derivation in your issue of to-day. It has, however, always appeared to me that a more probable source is the word γλαυξ, γλαυκος, an owl; and I should like to submit this origin to the profession. Considering the number of needless hybrid words which are yearly admitted to the English language, we doctors ought to struggle to keep our terminology accurate.

I am, Sir, yours truly,

March 20th, 1886. M.D. Durh.

NITRO-GLYCERINE TABLETS.

To the Editor of THE LANCET.

SIR,—By way of correction of an annotation in THE LANCET of to-day (p. 560), headed the "Poisons Act," as the inventor and advertiser of the above, I beg to say: (1) They are not "commonly advertised as a popular remedy." They are only advertised in THE LANCET, the medical and pharmaceutical journals, and in a circular issued solely to the medical profession and the drug trade (one enclosed). (2) As to their being "objectionable and dangerous chocolate drops," their portability and palatability, and the relief they have afforded to late members of the Medical Council and patients of all grades, dispose of the first. With regard to the second, in my large experience of them I have not met with a single case of danger from their use, nor am I aware of any case recorded. I believe they have afforded more relief to painful human sufferin than any medicinal preparation introduced during the last twenty years. Should they be placed in the poisons schedule I should be compelled to label them "Legally Poison, but not Poisonous." (3) The 1 per cent. alcoholic solution of nitro-glycerine evaporates and leaves a residue uncertain in strength. The tablets are always stable, safe, and in divided doses. They contain $\frac{1}{100}$ gr. in each, but can be made to contain any dose. They are quick in action, not like the pills which I first prepared; these require time to dissolve and are slow in giving relief to acute pain. I prepared the tablets in the first instance at the request of a medical writer on nitro-glycerine who had found this exceedingly useful in angina pectoris. He wished to have it in a portable form for patients who were attacked when away from home. The Home Office refused me leave to buy nitro-glycerine in any form. I always make the mass for my tablets personally with my life in my hands. They represent an achievement in pharmacy second to none during the last century. The most dangerous and unstable explosive of modern times, by my process I prepare for medical use in a perfectly safe, stable, palatable, and portable condition in divided doses, and supply them at the rate of seven doses for a penny to hospitals buying a pound for the use of their patients. As to the "egregious blunder" of inserting them in the British Pharmacopœia, I pass this over. Pharmacists have no voice in compiling our national pharmacopœia; but I may say if a 1 per cent. alcoholic solution be preferred, there is nothing to prevent physicians prescribing as much as they please of it, as every respectable pharmacist has it in stock; but it is uncertain in strength. A 1 per cent. oily solution, as I have suggested, is much more uniform; but neither is portable. Nearly one-half the tablets I sell are exported, principally to Greater Britain, where no shipment of alcoholic solution of nitro-glycerine can be made as ordinary cargo, and where suffering patients would have to continue their sufferings unless the tablets could be obtained. The writer of the annotation referred to overlooks the fact that chloroform is in Part II. of the Poisons Schedule of the Pharmacy Act, 1868.—Yours truly,

March 20th, 1886. W. MARTINDALE.

*** Mr. Martindale forgets that he is not the only maker and advertiser of nitro-glycerine tablets. As a matter of fact, they are commonly sold to patients without a prescription or order of any kind from a doctor. We are assured on good authority that the chocolate lozenges are not so prompt in their action as the 1 per cent. alcoholic solution, and that in several cases their injudicious use has been attended with untoward results.—ED. L.

E.C.L.C.—The question is one we do not see our way usefully to discuss at the present time.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—In my article on the "Medical History of the Suakim Expeditionary Force," inserted in your issue of the 20th ult., from "the treatment adopted" to "two to three ounces with iced water" (lines thirty-four to fifty-four of the second column), should have been inserted after "from 9 to 12 P.M." (line twenty).—Yours obediently,

Suakim, March 10th, 1886. J. ROCHEID FORREST, Surgeon, Army Medical Staff.

THE DISPOSAL OF THE SEWAGE OF LONDON.

IN an article which appeared in our columns on the 20th inst., upon the scheme of the Metropolitan Board of Works for the disposal of the sewage of London, we omitted to state that a full text of the report as submitted to the Board appeared in the *Metropolitan* of the 13th inst., as well as in *The Times* of that date, to whose report we referred.

C. H. W.—The Royal Medical Benevolent College, Epsom.

OWING to pressure on our space we are compelled to hold over many articles and communications, already in type.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. E. A. Sansom, London; Mr. C. S. Jeaffreson, Newcastle-on-Tyne; Dr. Jas. Wilson, Liverpool; Dr. Pavy, London; Mr. Ransford, London; Dr. R. Lee, London; Mr. G. Cowell, London; Dr. Kirby, Beckenham; Mr. J. Cooper, Middlesborough; Mr. W. Thomas, Birmingham; Dr. Lycett; Mr. Abbott, Tunbridge Wells; Dr. Kirk, Partick; Mr. C. F. Smith, Carlisle; Rev. A. Brinckman, London; Dr. Barnes, London; Mr. J. Johnson, Clare; Dr. Latham, Cambridge; Major Allsop; Mr. H. C. Gillies, Brockley; Mr. J. Odling, London; Mr. W. MacGregor, Bedford; Dr. W. Curran, London; Mr. Jennings, London; Mr. Jessett, London; Surg.-Major Evatt; Dr. Blenkinsop, London; Dr. Fenwick, London; Mr. J. Gulstonian Lectures

ON

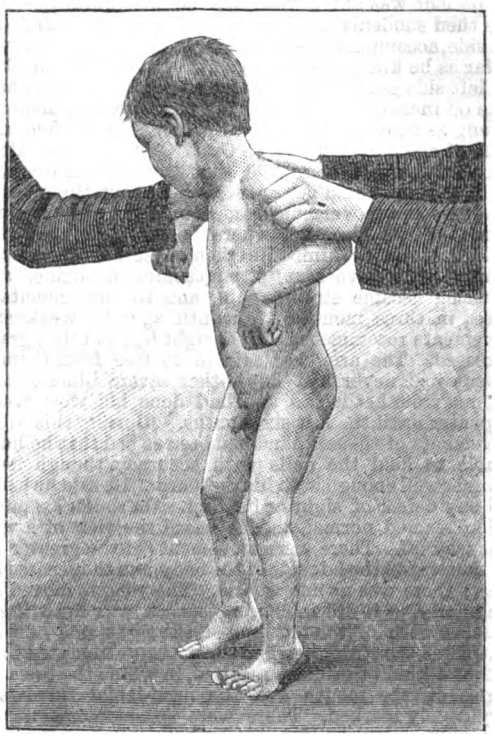
SPASM IN CHRONIC NERVE DISEASE.

Delivered at the Royal College of Physicians of London, March, 1886.

BY SEYMOUR J. SHARKEY, M.B., F.R.C.P.,

ASSISTANT-PHYSICIAN AND JOINT-LECTURER ON PATHOLOGY AT ST. THOMAS'S HOSPITAL.

LECTURE II.



MR. PRESIDENT AND GENTLEMEN,—In my first lecture I considered the part played by chronic diseases, which injure the intracranial portion of the pyramidal tract, in the production of spasm. It was pointed out that the results are similar, whether the lesion is situated in the motor area of the cortex, in the central ganglia, in the crus, pons, or medulla, provided that the function of the fibres of the pyramidal tract be interrupted. A point which is of great importance, and which will be again referred to when we come to a consideration of functional spasm, is this, that congenital defects of portions of the central nervous system are as capable as destructive diseases of producing paralysis of limbs, accompanied by spasm.

Case of Congenital Spastic Hemiplegia.—In the Med.-Chir. Trans. (vol. lxvi., 1883) I published a case of Asymmetry of the Brain, and discussed the bearing of the anatomical peculiarities of the specimen on the question of the connexion between the optic nerves and certain definite areas of the cerebral cortex. But the case is also a good example of the disease called congenital spastic hemiplegia, and for this reason I refer to it here. E. A—— was admitted into St. Thomas's Hospital, under the care of Mr. Mason, owing to injuries received by the fall of a house; and she died of the results of the accident. I never saw her until I performed the post-mortem examination upon her; and no account was obtained during her lifetime of the abnormality in her right arm and leg, nor of the state of her mind and special senses. After death, her father informed me that his daughter had always been healthy up to the time of the accident, which proved fatal in a few weeks; that she had never suffered from fits or other nervous affections; that from her very birth she had had a small and stiff right arm; and that she had always been left-handed and a little lame. He had never noticed any mental deficiency; and she had never complained of her sight, hearing, or other senses. No peculiarity in her eyes, speech, or aspect was noticed during her stay in the hospital; but the sister of the ward said that she struck her as being intellectually dull, even for a person in her position in life. At the necropsy both the right arm and leg were seen to be smaller than their fellows, though they were otherwise normally formed; and the muscles examined presented the rich brown colour of health. The right wrist measured 4¾ in., the left 5⅜ in.; the right forearm 6½ in., the left 8 in. The circumference of the left leg, round the calf, exceeded that of the right by one inch. The heart, lungs, and other viscera were healthy, with the exception of the kidneys and the bladder, which were in a state of acute inflammation. The skull and the membranes of the brain were normal, as were the intracranial bloodvessels, nor was there any marked inequality of the latter on the two sides.

I need not enter into the minute details given in the paper referred to, but may simply state that both the history of the patient and the anatomical peculiarities of the brain showed that it was a case of malformation of one portion of the left hemisphere, and arrest of development of the remainder. The most striking characteristics of the specimen which is here shown (Figs. 14, 15, 16, 17) were: (1) the general arrest of development of the left hemisphere, including the motor convolutions; (2) the small size of the corresponding crus cerebri and anterior pyramid; (3) the absence of the angular gyrus and superior temporo-sphenoidal convolutions, together with the fusion of some of the other convolutions of the left temporo-sphenoidal lobe; (4) the small size of the optic tract, optic thalamus, and corpora geniculata on the same side. The spinal cord was subsequently examined, and, throughout its whole length, it was seen that the right lateral column was smaller than the left, and the left column of Türck smaller than the right. (Fig. 18.) These differences were most marked in the upper regions of the cord, and became less and less so towards the lumbar enlargement. The microscope showed that in those parts where reduction in size was evident, even to the naked eye, the nerve fibres were fewer in number and the tissues a little denser than in health; and the general impression left upon the observer's mind was that there was an absence of nerve fibres, and consequent undue prominence of the connective tissue. In this case there was clearly congenital absence of part of the motor convolutions and of the corresponding pyramidal tract; and, clinically, paralysis with spasm was observed. Such a combination seems to prove that the mere absence of the controlling impulses which in healthy subjects traverse the pyramidal tract is capable of giving rise to a spastic condition of the limbs.

Congenital defects similar to that which has just been described may be bilateral, and produce a condition about which a good deal has been written, and which is termed "infantile spasmodic paralysis," or "spastic paraplegia of infancy." Dr. Hadden, writing on this disease in *Brain* (vol. vi., 1884), says, "the lower extremities are more or less flexed at the hip- and knee-joints, the thighs are rigid and adducted, the knees in contact, the legs inclined outwards, and the heels often drawn up from the ground by the contraction of the gastrocnemii." Figs. 19 and 20[1] represent a well-marked but not extreme case of the kind, which was under Mr. Clutton's care in St. Thomas's Hospital. The child was an idiot, as many of them are. Dr. Ross has proved, by post-mortem evidence, that defects in the development of the brain can produce this condition. In *Brain* (vol. i., 477), he records a case of the disease in which he found at the necropsy a congenital defect in the motor convolutions on both sides, and absence of the large pyramidal cells normally existing in them. He found the same condition of the spinal cord as was present in my case of congenital spastic hemiplegia—namely, absence of a certain amount of the lateral columns,—but no other

abnormality. Whether all cases of congenital paralysis and spasm of the limbs be due to arrest of development of portions of the brain is at present uncertain, but it is not at all improbable that intra-uterine disease of parts already formed may be the explanation of some. Contracture, or fixed spasm, is a comparatively frequent result of cerebral lesions which interrupt permanently the voluntary impulses proceeding from the cortex. But, in addition, mobile spasms have been observed in great variety, either after hemiplegia or independently of it. Sometimes they attend voluntary movements only; sometimes they are involuntary and continuous; but in all of them the retention of a large amount of voluntary control over the limbs affected is a striking feature. In addition to the mobile spasm, there is often a certain degree of fixed spasm, though a marked degree of the latter would be incompatible with the development of the former. Continuous movements of the hands and toes have been termed "athetosis." The following is a case of the kind which I reported in *Brain* for April, 1885. It is a good example of this condition, though rare because of the number of muscles affected, and because the movements appeared after many years on the opposite side of the body.

G——, aged twenty-four, came under my care as an out-patient at St. Thomas's Hospital on March 26th, 1884. Until the patient was three years old he was quite healthy; he was then suddenly attacked with loss of power all down the left side, accompanied by repeated and prolonged convulsions. As far as he knew, the movements of the limbs and face on the left side gradually followed the loss of power, and had gone on increasing ever since; at any rate, they had done so as long as he could remember. When between four and five years of age he was taken to Great Ormond-street Hospital, where his parents were told that the movements were so slight that he would get over them. About three years ago weakness and movements came on in the right leg, and he went to Guy's Hospital, where he was told that nothing could be done for him. He then consulted a homœopathic chemist, who gave him "strengthening medicine," and his right leg became strong again, and the movements in it ceased in three months. A month ago the weakness and movements recommenced in the right leg, and they gradually increased. The arm was said to be free from them. The patient had never had any other severe illness, had not suffered from headaches, and had done his work well as a carpenter until the last six months. During this time the movements of the left hand had been so bad that he had been unable to hold the nails with accuracy, though he could hammer well enough with his right arm. He said he had never had any defect of sight or hearing. On rough examination, vision seemed normal, and he heard the tick of a watch a long way off. There were movements of the greater part of the muscles on the left side of the body, and they ceased during sleep; there was no anæsthesia. The tongue moved a little irregularly, as it did in chorea; speech was drawling. The muscles, both of the left and of the right side of the face contracted too strongly when the patient attempted to speak, so that a kind of grimace resulted, in which the lines at both angles of the mouth and the naso-labial furrows were very deeply marked. There were spasmodic, more or less regular, movements of the neck to the left, and the shoulder was rhythmically raised, and jerked slightly forwards and backwards. One could see the serrations of the left serratus magnus contracting rhythmically. The abdominal muscles were harder on the left side than on the right, but there were no evident movements in them. There were slight spasmodic movements in the left arm, but they were only slight. The hand, on the contrary, was markedly affected. There was constantly more or less rhythmical flexion and extension of the fingers, mainly at the metacarpo-phalangeal joints, with irregular flexion and extension of the phalangeal joints, and occasional separation of the fingers. In the left leg there were similar slight movements of the muscles, with marked movements of the toes, and most marked of the great toe. There were tremulous flexions and extensions, but the flexor longus pollicis was constantly contracted, so that the great toe was always riding over the others, and its proximal phalanx was usually at right angles to the metatarsal bone. In the right foot the movements were similar, but not so marked. In the right hand only the little finger moved, and that so slightly that the patient had not noticed it. The grasp of the right hand, though stronger than that of the left, appeared to be deficient in power; the patient said, however, that he had never noticed that it was weak. There was neither atrophy nor hypertrophy of the muscles of the limbs. The patellar reflex was unnaturally brisk on both sides, but there was no ankle-clonus. The patient seemed very intelligent, and said that his memory and mental power were very good. The fundus of the eyes and fields of vision were normal. The urine contained no albumen.

The next case is one of fixed combined with mobile spasm, and also differs from that just described in this, that there was no history of hemiplegia or monoplegia preceding the onset of the muscular contraction.

Case of Mobile and Persistent Muscular Spasm of the Upper Extremity.—E. F——, aged eleven, came to St. Thomas's Hospital as an out-patient, under me, in June, 1884. She was a very well made, intelligent, lively child, and in these respects was said to resemble the rest of her family. When she was nine months old the mother noticed that she held her left arm behind her back, and did not use it properly. Ever since the arm had been becoming gradually more distorted and useless. On examination it was found that the left arm was not undersized or atrophied, but that it was the seat of extreme distortion, which rendered it perfectly useless. The forearm was excessively pronated, so that the palm of the hand looked outwards, and the wrist was flexed; the metacarpo-phalangeal joints were extended, the proximal phalangeal joints hyper-extended, and the peripheral flexed. The elbow-joint was flexed, and looked unshapely. The metacarpo-phalangeal joint of the thumb was flexed, and the phalangeal joint hyper-extended; and the thumb, as a whole, was turned inwards towards the palm. All the parts described were rigidly fixed in these positions, apparently by the spasmodic action of the muscles. But the spasm could with difficulty be overcome, and then the limb assumed quite a new appearance. Thus, if pronation were rectified and the elbow bent, the wrist at once became extended, all the fingers flexed, and the thumb was turned into the palm of the hand beneath them. This state of affairs was only retained by keeping the elbow-joint flexed, and forcibly overcoming the tendency to excessive pronation. As soon as the latter was allowed to assert itself the whole limb at once returned to the original position. Sensation was unaffected. Dr. Kilner, who tested the electric condition of the affected parts, reported that the muscles reacted normally to the induced current, and presented very slight reaction of degeneration when the constant current was used. On giving chloroform the distortion almost entirely disappeared, the muscles were flaccid, and the tissues of the elbow-joint appeared very lax. The child had attended the Orthopædic Hospital for one year without deriving any benefit; but electricity had not been tried. Dr. Kilner was good enough to undertake treatment by this means, but though he continued it for weeks the condition underwent no improvement. On August 24th, 1885, I took her to have the abnormality photographed, and I then found that certain alterations had occurred in the condition of the hand and arm. The most marked change was that they were never still; in fact, the case might then have been called one of athetosis of the left upper extremity. The arm, when left alone, usually occupied a position midway between the perpendicular line of the body and a horizontal line drawn through the left shoulder-

FIG. 21A

FIG. 21B.

Showing position assumed when the wrist was flexed.

Digitized by Google

joint, and the latter was extended, the forearm pronated, the wrist flexed, and the fingers flexed at the peripheral phalangeal joint, and hyper-extended at the proximal. Such a degree of hyper-extension now existed in the metacarpo-phalangeal joint of the thumb that partial luxation had been produced. The child generally liked to hold the hand across the front of the body, with the fingers a little flexed. Irregular clonic jerks affected the whole arm from the shoulder, and the fingers were in more or less constant movement when left to themselves. There were occasional slight jerks of the left angle of the mouth, but the leg appeared free from any abnormality. The child asserted that she had always had these movements, though I certainly did not notice them when I first saw her. Figs. 21A and 21B represent the condition of things in January, 1886.

Mobile spasms do not always assume the characters which are described under the term "athetosis." Movements resembling more or less those of chorea, disseminated sclerosis, ataxy, and paralysis agitans, likewise occur.

On June 11th, 1885, a woman, aged sixty, came to my out-patient room, complaining of loss of power all down her left side; her face, arm, and leg were all weak, and there was a considerable degree of hemianæsthesia. This condition had slowly developed in the course of three months. Though she had had rheumatic fever twice, there was no apparent disease of her heart or other viscera, but her arteries were somewhat hard. By November moderate hemiplegic rigidity had developed, and, in addition, continuous movements exactly resembling those of paralysis agitans.

It is unnecessary to describe the various forms of mobile spasm which are seen at the bedside. Dr. Gowers has given an account of a considerable number (Trans. Royal Med.-Chir. Society, vol. lix.); and Charcot and others have also recorded cases. What concerns us more on the present occasion is the question of their pathology. Can they be attributed to any lesion constant either in its nature or in its position? The answer to this must be in the negative; but we have to confess at the same time that our knowledge of this class of spasm is very deficient. Gowers, in the paper already referred to, records a case of "post-hemiplegic incoördination," in which he found, at the necropsy, one lesion only, and that was a cicatricial induration confined to the optic thalamus, and unaccompanied by any pathological changes in the spinal cord. Weir Mitchell found the seat of the lesion in two cases in the corpora striata. In the *Revue de Médecine* for May, 1883, Emile Demange records the necropsy in nearly a dozen cases of post-hemiplegic mobile spasm; and among these is a case of hemiathetosis, in which there was extensive softening of the convolutions, but no disease of the central ganglia. In most of the cases the lesion or lesions were in the central ganglia, sometimes involving the internal capsule, and sometimes not. Hence it seems to me that we must agree with Demange when he says that these movements may occur from disease of any part of the motor tract in the brain; and he adds that the variety of movement does not depend upon the seat of the lesion, but rather upon the condition of the motor tract below the lesion.

All the varieties of mobile spasm seem to result from a mixture, in varying proportions, of paralysis, spasm, and irritation; and their development depends upon lesions which interfere with the perfect functions of the motor centres and fibres, but which do not completely interrupt them. That such a condition of incomplete destruction is competent to give rise to movements of the kind under consideration is shown by a case which I published in THE LANCET in a paper on Cerebral Localisation already referred to. The patient was a woman aged forty-six, who was admitted into St. Thomas's Hospital on July 20th, 1878, and died on July 21st, 1879. She was suffering from chronic renal disease, and on Jan. 18th, 1879, she complained of being unable to keep her left arm still. The movements both of the arm and leg soon became violent and disorderly. When asked to put her left hand to her face, she did so hesitatingly, and with a series of jerks which had no constant rhythm or direction. The same occurred on voluntary movement of the leg, while the right arm and leg were moved slowly and naturally. The jerking movements gradually subsided until, on Jan. 30th, the leg was freely and normally moved, while the left arm was almost completely paralysed, and, although it recovered some degree of power, it remained markedly paralysed to the end of her life. After death the middle part of the ascending parietal convolution on the right was softened, shrunken, and of an orange colour. It is clear in this instance that the involuntary movements of the limb occurred at the time when the cortical grey matter was in the early stages of softening, and that they ceased when paralysis resulted from its complete disorganisation.

In concluding the consideration of spasm in connexion with diseases of the intracranial portions of the voluntary motor path, it is necessary to refer to a statement which I made in my first lecture—namely, that "our present knowledge of anatomy, physiology, and pathology does not justify us in concluding that there is any efferent motor connexion between the brain and the spinal cord, except the pyramidal tract, direct and crossed, disease of which gives rise to chronic muscular spasm. Evidence in support of this view will appear in subsequent portions of these lectures." In saying this I wished to exclude the cerebellum and the central ganglia from consideration, since any rigidity or spasmodic contraction of muscles which arises in connexion with diseases of the areas they occupy seems to depend upon involvement of the pyramidal tract, which passes close by them. Evidence has also been supplied in support of this view as far as the cerebellum is concerned. Let me now record a case which shows that destruction of the central ganglia produces no spasm so long as the neighbouring internal capsule is intact.

C. B——, aged thirty-nine, had an attack of right hemiplegia ten years before death and another somewhat later. He died of carcinoma of the cæcum, having long recovered completely from all paralytic symptoms. At the necropsy I found that the hemispheres were free from disease. On exposing the ventricles, it was at once seen that the left caudate nucleus was very much shrunken and of a yellowish hue. Both optic thalami and the right nucleus caudatus looked healthy. The left crus cerebri was small and discoloured along its inner third, and the left side of the pons Varolii was evidently flattened. Nothing abnormal was noticed in the crus cerebelli on either side, and the pyramids in the medulla oblongata were equal and natural. No descending degeneration was to be discovered in the spinal cord with the naked eye. The brain was then set aside to harden in alcohol before any further examination was made. A series of horizontal sections through the hemispheres and central ganglia showed that there was hardly anything left of the nucleus caudatus or of the nucleus lenticularis on the left side, but there were no evident changes in either division of the internal capsule. The optic thalamus was a little smaller than its fellow on the opposite side, while all the central ganglia on the right were healthy. (Fig. 22.) A vertical section through the crura cerebri showed very marked atrophy of the left as compared with the right. A similar diminution in size was observable in the left half of the pons (Fig. 23); but the pyramids and all other divisions of the medulla oblongata were healthy and symmetrical.

This case shows that disease so severe as to result in almost total obliteration of the corpus striatum may produce hemiplegia, which passes off without leaving rigidity, paralysis, or any other symptom behind. And, secondly, it proves, as far as any single case can prove, that the efferent fibres of the corpus striatum do not pass down further than the pons Varolii or medulla oblongata.

The continuous degeneration of the lateral column through the whole length of the spinal cord in cerebral lesions shows that the fibres are not interrupted by entering ganglionic centres, but pass straight to their several destinations in the anterior cornua. It will be readily understood that if disease destroy them at any level in the spinal cord, degeneration will occur in them below, and give rise to symptoms of hyper-physiological activity of the spinal centres with which they are connected, similar to those which occur when the disease is intracranial. In the latter case all the spinal centres which are under voluntary control are affected; in the former, only a certain number, more or less numerous according as the lesion is situated high up or low down in the cord. There is this difference, too, that in cerebral disease the rule is to find the contracture unilateral, in lesions of the cord bilateral. But this is merely because the pyramidal tracts in that part of the brain where they are most liable to be interrupted by disease lie at some distance from each other; whereas in the spinal cord they are so close together as usually to be involved in the same pathological changes. The symptoms, however, of disease of the lateral columns of the cord are the same, whether it follow cerebral or spinal lesions. The affections of these columns are either primary or secondary.

Digitized by Google

and the symptoms differ slightly accordingly. Thus, if a primary chronic inflammation attack them, as in primary lateral sclerosis or disseminated sclerosis, paresis of the corresponding muscles is an early symptom, and tremors of the limbs when moved, increased tendon reflexes, and clonus soon follow. In addition to these, transitory involuntary contractions and longer though still intermitting spasms occur, and finally culminate in persistent rigidity. When the latter has fairly set in, the muscles can only be loosed from their slavery by a process which condemns them to perpetual inaction. Their masters, the cells in the anterior cornua, may be attacked and die; but the muscles perish with them, and the tendon reflexes and other signs of their activity disappear for ever. But the lateral columns are more often affected secondarily than primarily, and then the symptoms which culminate in spasm follow those which characterise the original disease. Thus we often see cases of myelitis run their course to destruction of a portion of the spinal cord, and rigid contracture of the limbs then supervenes. Such disease occurs more frequently in parts below the cervical region than in those above it, and consequently the legs are more often the seat of rigidity than the arms. But matters are not always so simple as this, for a lesion of the lateral columns may be combined with that of some other tract of fibres; and a combination of symptoms then presents itself, some being attributable to disease of one tract, and some to disease of the other. If we are to draw correct conclusions with regard to the localisation of diseases of the spinal cord and their progress, we must never lose sight of the phenomena which characterise the healthy action of the nervous system. Physiology is the only safe guide for the diagnosis of the positions occupied by disease. Again, although pressure upon the pyramidal fibres interrupts their functional activity, the symptoms are very different according to the manner in which the pressure is applied, whether from without or from within the cord. As time will not permit me to enter into detail upon all those diseases of the spinal cord which give rise to spasm, I shall try to illustrate from my own experience the two points to which I have specially referred—namely, first, the difference in the results of pressure applied upon the cord from without and from within; and, secondly, the modification which occurs in the symptoms of disease of the lateral columns when it is combined with disease of other parts of the cord. The following case is a good instance of pressure on the spinal cord from without, giving rise to interference with the function of the lateral columns and to extreme contracture of the lower limbs.

Case of Tumour (Myxoma) on a Spinal Nerve, which pressed upon the Cord and produced Paralysis and Spasmodic Contraction of the Lower Limbs. — A. J——, aged twenty-four, blacksmith, was admitted into St. Thomas's Hospital, under the care of Dr. Bristowe, on April 20th, 1876. His family history was unimportant, and until his present illness began he had always enjoyed good health. He had drunk freely both beer and spirits. He was in the habit of lifting heavy weights, and had occasionally "ricked" his back, but had never suffered from any serious injury. In August, 1875, he began to feel a sensation of weakness in the loins, but he had no actual pain. This was followed in November, 1875, by a certain degree of weakness in walking, which slowly increased, so that he became unable to walk at all two months before admission. During this period he suffered from cramp, with slight loss of power in his left arm, and from occasional attacks of sharp shooting pains and cramp in his legs. He had had no loss of sensation or numbness anywhere. On admission, he was found to have marked paraplegia, but no loss of sensation. He suffered from cramps, and his legs at times were flexed involuntarily. He had incomplete control over his evacuations. His left hand and arm were not as powerful as his right. All his organs appeared to be healthy, and he had no albumen or pus in his urine. Somewhat later, painful contraction of the adductor muscles of the thighs used to come on and last for hours; and he had slight numbness as high as the umbilicus. When these attacks of spasm supervened in the muscles of the leg, pain and similar cramps were experienced in the left arm. The remainder of his life was very painful. His legs became gradually more and more permanently and rigidly flexed and adducted, and bedsores developed over the internal aspects of the knees, where they were forced against each other, as well as over the sacrum and trochanters. Sensation, however, rather improved than deteriorated. Finally, incontinence of the evacuations, cystitis, and hectic fever set in; and the patient died on August 17th, four months after admission, and one year from the date of his first symptoms. At the necropsy most of the organs were found to be perfectly healthy, the urinary tract and spinal cord alone presenting evidences of disease. The pelves of the kidneys and the ureters were inflamed, and the kidneys were large and succulent. On one of the anterior spinal nerves, which originated just at the termination of the cervical enlargement, was a tumour about as large as a medium-sized marble. It was firm, pale in colour, and covered with a perfectly smooth fibrous sheath. The nerve was lost in its substance, but the tumour was free from adhesions with the spinal cord and all the surrounding structures. It was wedged in between the bones forming the spinal canal on the one hand and the anterior surface of the spinal cord on the other, so that the latter was flattened by it anteriorly and slightly laterally. The tumour was a myxoma.

The motor phenomena which characterised this patient's history were paralysis, attacks of tetanic spasms, and, finally, persistent rigidity of the legs. Making allowance for the position at which the pressure was applied to the spinal cord—namely, below the origin of the nerves supplying the arms,—the occurrence of tetanic spasms in the legs from time to time reminds us forcibly of similar but more extensive spasms which occur when the disease occupies the base of the brain or the cerebellum, and, I think, gives support to the conclusions which were drawn as to the part played by the cerebellum in their production. A point which should be specially noted in this case is this, that when the pains and tetanic spasms occurred, pain and spasm were likewise felt in parts supplied by the nerve on which the tumour was situated. These attacks of spasm in the legs, which were intermittent, appear then to have been produced by changes occurring in the tumour, which also showed their presence by increased pressure on the nerves for the arm which it involved. The same intermittence was observed in the spasmodic attacks produced by the tumours which occupied the base of the brain, and the same thing occurs when a tumour presses upon the cerebral cortex. We may conclude, therefore, that in all such cases the convulsions are due primarily to alteration in the condition of the tumour, though we cannot say in what the alteration consists.

[ERRATUM.—On page 532, second column, six lines from the bottom, for "lenticulo-striate and lenticulo-optic arteries" read "lenticulo-striate artery."]

Croonian Lectures

ON

SOME POINTS IN THE PATHOLOGY OF RHEUMATISM, GOUT, AND DIABETES.

Delivered at the Royal College of Physicians of London, April, 1886.

BY P. W. LATHAM, M.A., M.D., F.R.C.P.,

DOWNING PROFESSOR OF MEDICINE, CAMBRIDGE; SENIOR PHYSICIAN TO ADDENBROOKE'S HOSPITAL.

LECTURE I.—ABSTRACT.

THE three disorders of rheumatism, gout, and diabetes are classed together because they seem to possess a certain relationship with each other. Cases occur in which it is difficult to decide whether the disease must be regarded as rheumatic or gouty. Not infrequently transient diabetes appears as the harbinger of a gouty attack; and, on the other hand, gouty, rheumatic, or neuralgic pains are very common accompaniments of diabetes. In all we have changes, differing, however, in character, showing themselves in the blood, the result of abnormal metabolism either in the muscular or glandular tissues. What are the changes that take place in the tissues or in the blood? In attempting to answer these inquiries we meet at the outset with a most serious difficulty. We

Digitized by Google

require to know what the constitution of the particular tissue is, its proximate constituents, its structural formula, *not* its ultimate chemical composition. We do not know what are the proximate elements which make up living tissue, nor what are the chemical changes which take place as it performs its function, nor the alteration in the arrangement of its molecules as it passes from an active to an effete state. By chemical investigation it has been shown that various complex bodies which did not exist as such in the living tissue can be extracted from the different tissues after death. This subject was illustrated by a reference to the changes that occur in blood after being shed and to the chemical differences of living and dead muscle. No definite agreement has yet been arrived at as to the constitution of dead proteid, or as to the manner in which the various substances, leucine, tyrosine, &c., are contained in it. Lieberkühn gives its formula as $C_{72}H_{112}N_{18}O_{22}S$; and this, according to Hlasiwetz and Habermann, by hydration, may be split up into aspartic acid, glutamic acid, leucine, tyrosine, and ammonia. Seeing the difficulty of studying the dead tissues, Dr. Latham said it might appear presumptuous and rash on his part to endeavour to assign a molecular structure chemically to living tissue. Still, he would make the attempt and advance a theory which appeared to him to explain many changes in the tissues. It was well known that lactic acid, leucine, glycocine, and other bodies could be prepared in the laboratory from a particular series of cyanogen compounds, the so-called cyanalcohols or cyanhydrins—bodies which may be obtained by oxidising the various alcohols, and so forming the aldehyde, and then combining this with hydrocyanic acid. Thus:

$$\underset{\text{ethylic alcohol.}}{C_2H_5HO} + O = \underset{\text{ethaldehyde.}}{CH_3 . CHO} + H_2O$$

$$\underset{\text{ethaldehyde.}}{CH_3 . CHO} + HCN = \underset{\text{cyanethylic alcohol.}}{CH_3 . CH(CN)OH}$$

These cyanalcohols are very unstable bodies; treated with ammonia they form a series of cyanamides, also very unstable, and easily undergo condensation, being converted into imido-nitriles with elimination of ammonia. It is suggested that these cyanogen compounds possess some properties of living tissue—viz., those of undergoing intra-molecular change, and also condensation. May not albumen itself be regarded simply as a compound made up of these elements, if from these cyanogen compounds we can obtain the various products which result from the disintegration of albumen? Dr. Latham then pointed out some of the animal products that could be obtained from these cyanalcohols: leucine, which could be artificially obtained by oxidising amylic alcohol; then mixing with aqueous ammonia the aldehyde is converted into valeral ammonia, and this digested with hydrocyanic acid and hydrochloric acid is converted into leucine. This is the usual way of obtaining leucine artificially, but Tiemann has shown that the amido-acids both of the fatty and aromatic series may be obtained by converting the aldehydes and ketones into cyanhydrins and then into amido-nitriles, or cyanamides. Leucine prepared in this way is not quite identical with animal leucine. It is suggested that, just as sarcolactic acid is a compound of ethidene and ethene lactic acids, so leucine is a compound of several amido-acids, the molecule C_5H_{10} being made up in different ways. Amido-isovaleric acid or butalanine has been found in the pancreas of the ox, and it can be artificially prepared from the cyanalcohols; it has also been prepared by Schützenberger from albumen. Amido-butyric acid can be formed from cyanalcohols, and has been separated from albumen. By oxidation oxy-isobutyric acid is resolved into carbonic acid and acetone, a substance that sometimes appears in diabetic urine. Ethidene and ethene cyanalcohols may be prepared (1) by oxidising ethylic alcohol and treating the aldehyde so obtained with hydrocyanic acid; (2) by converting ethene alcohol or glycol into a cyanalcohol. From these cyanalcohols the corresponding amido-acids or alanines may be obtained. Alanine or amido-propionic acid was also among the products Schützenberger obtained from albumen.

The lecturer then proceeded to show how from the various alcohols, amylic, ethylic, &c., converted into aldehydes and then into cyanalcohols, the corresponding amido bodies, glycocine, leucine, &c., could be obtained, and all the acids of the acetic series, as well as those of the lactic acid series, which may also be prepared from animal substances. The formation of lactic acid and glycocine were thus referred to:—Lactic acid, again, is an important product of the animal organism. It is developed when a living muscle contracts, and is produced when a muscle dies. The variety of this acid, which is obtained from the disintegration of albuminous compounds, and is formed during the contraction of muscle fibres (sarcolactic acid), may be regarded as a mixture of two kinds of lactic acid, the more abundant being paralactic acid or ethidene lactic acid $CH_2 . CH \begin{cases} OH \\ COOH \end{cases}$, the other ethene lactic acid $CH_2 . CH_2 \begin{cases} OH \\ COOH. \end{cases}$ By treating ethidene cyanalcohol with acids or alkalies, paralactic or ethidene lactic acid is obtained; by treating ethene cyanalcohol in the same way, ethene lactic acid is obtained.

The next point is whether the reverse process can be effected. Can the amido bodies in the system be converted into the cyanalcohols, and can we theoretically build up albumen from such bodies? The first step in this direction is indicated in what follows when amylaceous matter or sugar is introduced into the alimentary canal. A certain accumulation of glycogen takes place in the liver, and, further, a considerable quantity of sugar can be slowly injected into the portal vein without any appearing in the urine. The sugar loses a molecule of water, and becomes glycogen in the liver.

Now, in order to obtain the various amido-acids from albuminous tissue the reverse process must be adopted, the tissue must be hydrated, and a certain amount of water must enter into combination with it. Having shown that leucine and tyrosine, regarded as amido acids, exist in the intestines, and having quoted the evidence from Foster's physiology that leucine and probably tyrosine can become converted by the liver into urea, though there is much difficulty in understanding how this is effected unless we suppose that the amido acids first pass through an ammonia phase, Dr. Latham drew attention to the almost complete disappearance of urea from the urine in cases of acute yellow atrophy of the liver, leucine and tyrosine being abundant. The experiments of Solnikoff, too, show that the urea which passes out of the system by the kidneys enters the circulation with the blood which issues from the liver.

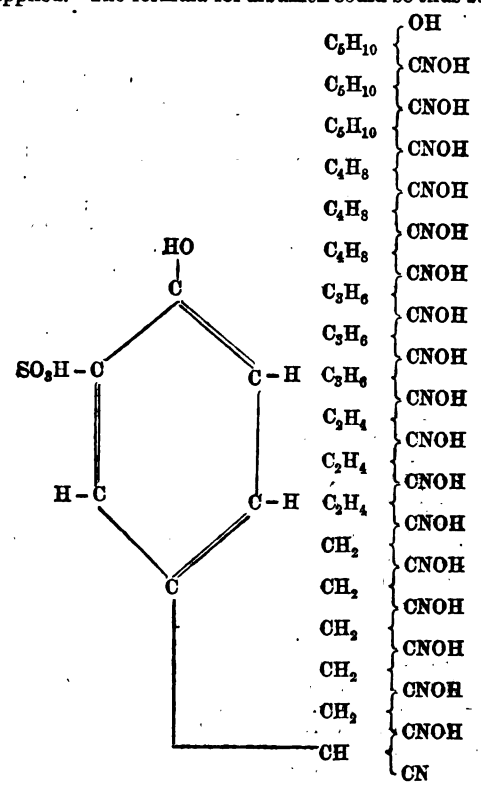
It is hardly intelligible that the nitrogen in the fresh nutritive material should immediately be transformed into urea and pass out of the system. These amido acids or glycines are capable of uniting with each other, and their molecular weights are at least double as great as their formulæ would indicate (Hofmeister). Now as the function of the liver in forming glycogen seems to be dehydration of glucose, the question naturally suggests itself: What compounds would result from the liver acting in the same way on these duplex or triple glycines? What substances would be produced by their dehydration? Can they in any way be converted into a series of cyanalcohols?

In 1828 Wöhler showed that urea $CO \begin{cases} NH_2 \\ NH_2 \end{cases}$ can be produced by molecular transformation of $CNO . NH_4$ (ammonium cyanate) by simply heating a solution of the latter. Pflüger, in calling attention to the great molecular energy of the cyanogen compounds, suggested that the functional metabolism of protoplasm by which energy is set free may be compared to the conversion of the energetic unstable cyanogen compounds into the less energetic and more stable amides. In other words, ammonium cyanate is a type of living and urea of dead nitrogen, and the conversion of the former into the latter is an image of the essential change that takes place when a living proteid dies. Dr. Latham then showed how it was possible chemically to produce an *atomic* combination of the cyanalcohols united to a cyanamide and an acid by making glycocine go through various hydrations and dehydrations. Another glycine—tyrosine—$C_6H_4 \begin{cases} OH \\ C_2H_3(NH_2)\ COOH \end{cases}$ or para-oxyphenyl-amido-propionic acid, could be obtained from proteids. By combining tyrosine with glycocine, H_2O, being eliminated, we should obtain a cyanogen compound. Bearing in mind that some cyanogen compounds by condensation of three molecules form new compounds, such as

$$\underset{\text{cyanic acid}}{3CNOH} = \underset{\text{cyanuric acid,}}{C_3N_3O_3H_3}$$

we may combine the compound of tyrosine and glycocine with three molecules derived from glycocine, and three molecules derived from each of the other glycines in the series including leucine; we should then obtain a very complex com-

Digitized by Google



pound of cyanalcohols, the molecule COOH in the one series combining with NH_2 of the other to form CNOH. Then, combining the COOH and NH_2 with other molecules of the same composition, and replacing one of the hydrogen atoms of the benzene nucleus by SO_3H, we should obtain an enormously complex molecule, to which, if the molecule of CNOH be added, we should have a chemical formula almost identical with that given by Lieberkühn for albumen (*vide posted*). Dr. Latham next assumed for the nonce that albumen was built up of the above indicated cyanalcohols united to a benzene nucleus, the molecules being held together by some force vital or otherwise, and considered whether a body so constituted would afford an explanation of the changes that take place in the muscular tissues in its active and quiescent state. If the cyanalcohols were detached separately, they could be converted by hydration into the acids of the lactic acid series, and by combining them with ammonia into the various cyanamides, which, hydrated, are transformed into the glycines—glycocine, tyrosine, &c. The molecules making up these cyanalcohols may be detached in groups varying with the power which holds them together. The following is one change which may take place. By the hydration or decomposition of the separate cyanalcohols lowest in the series, we should have the corresponding acid formed and ammonia liberated; the nascent ammonia may, however, combine with the hydroxyl of the next molecule in the chain to form a cyanamide, which, hydrated, would form the amido acid, ammonia being again liberated and forming a cyanamide with the next molecule higher up, and so on all through the different series. These series were illustrated by showing how creatinine and creatine could be formed from the synthetically constructed molecules. Another mode in which the molecules may become detached was by the ammonia liberated by hydration, combining with the molecule CNOH to form $CNO.NH_4$, which if detached would in the blood as out of the body be converted into urea. In this way we pass from the lower cyanalcohols to the higher with the formation of urea. Here we have not only an explanation of the formation of urea in the tissues, but the reason why the amido acids obtained from the tissues possess different properties from those made in the laboratory. There is another mode in which these molecules may split up, which is interesting from two points of view. It appears to explain the formation of lactic acid and carbonic acid when a muscle contracts or when it dies, and it seems to throw light on the formation of tyrosine. If the molecule $CH_2\{^{OH}_{CNOH}$ $CN_2\{^{CNOH}_{CN}$ were hydrated, forming $CH_2\{^{OH}_{CNOH}$ $CH_2\{^{CNOH}_{COOH}$ and the portion CNOH then detached, the latter would be decomposed at once into CO_2 and NH_3, and we should have lactic acid formed:

$$\underset{\text{lactic acid}}{CH_2-OH\\ |\\ CH_2-COOH} + \underset{\text{carbonic acid}}{CO_2} + \underset{\text{ammonia}}{NH_3}$$

the NH_3 combining with some other cyanalcohol to form a cyanamide.

Changes similar to these offer a very simple explanation of the formation of the cyanalcohols in plants, and as a consideration of these changes would help to explain the metabolic changes in the liver Dr. Latham briefly discussed them. In plants, CO_2 entering by the leaves combines with H_2O sent up from the roots to form methaldehyde H.CHO and oxygen O_2, a volume of oxygen equal to that of the CO_2 absorbed being exhaled by the plant.

MM. Loew and Bokorny and Pringsheim have shown that that there is a substance in living plasma which has the property of reducing silver salts, and for this reason is regarded as an aldehyde which results from the combination in the plant of CO_2 and H_2O. Methylic aldehyde by condensation becomes glucose, and the latter by dehydration starch; but if, instead of undergoing condensation, the aldehyde is oxidised, we get formic acid, which combining with NH_3 absorbed from the roots of the plant becomes ammonium formate, which dehydrated is converted into HCN. The hydrocyanic acid now combines with methylic aldehyde to form the cyanalcohol $CH_2\{^{OH}_{CN}$ and from condensation of these molecules with the separation of CNOH other cyanalcohols are formed. From such considerations, and from what has been said above as to urea, it would appear that when the amido acids are transformed into cyanalcohols and pass into the liver, condensation takes place with the formation of higher cyanalcohols and separation of CNOH, and that this change is constantly taking place all through the albuminous chain, the CNOH either combining with NH_3 to form urea or splitting up into CO_2 and NH_3. In this way the glycocine in the alimentary canal would on passing into the liver be transformed into $C_2H_4\{^{OH}_{CN}$ and CNOH, but we have no explanation of the origin of the lowest cyanalcohol. But if in plants glucose is a condensation product of methylic aldehyde, it is then no violent assumption that in the liver the glycogen after being transformed into glucose is resolved into its elements of six molecules of methylic aldehyde, and that this, by oxidation, combination with NH_3, and dehydration, is transformed, as in plants, into the lowest cyanalcohol of the series, $CH_2\{^{OH}_{CN}$. This view is supported by the experiments of Nägeli, which showed that albumen can be formed by fungi whose nutriment consists exclusively of sugar mixed with ammonia. By reviewing the constitution of tyrosine and deriving it from the cyanalcohol obtained from oxy-benzoin aldehyde, the lecturer showed how the molecule CNOH, which was wanting in his formula for albumen, could be supplied. The formula for albumen could be thus stated:

—a substance whose composition is $C_{72}H_{118}N_{18}O_{22}S$, and differs from Lieberkühn's formula by six atoms of hydrogen. Dr. Latham said he had thus endeavoured to show that albumen is a compound of cyanalcohols united to a benzene nucleus, these being derived from the various aldehydes, glycols, and ketones, or that they may be formed in the living body by the dehydration of the amido acids; that from a body so constituted all the different substances may be obtained which have been extracted from albuminoid tissues; that lactic acid is obtained in two ways, either from $C_2H_4\{^{OH}_{CN}$, or from changes and condensation in $CH_2\{^{OH}_{CN}$, with the simultaneous development of CO_2, a result which is brought about when a muscle contracts or when it dies; and that urea may be obtained from one series of cyanalcohols with the production of a cyanalcohol higher in the series. Such a compound of cyanalcohols could not be far off from the molecular constitution of albumen. Taking this view of the constitution of albumen, the

Digitized by Google

following may be given as a summary of the nutritive changes:—

The amido acids, glycocine, leucine, tyrosine, &c., in passing from the alimentary canal to the liver, are dehydrated, forming a series of cyanhydrins or cyanalcohols attached to a benzene nucleus, and then pass into the circulation. In the tissues these cyanalcohols, partly by condensation, partly by hydration and oxidation, give rise to the various effete products which are eliminated from the system chiefly in the form of carbonic acid and urea.

According to Tiemann, the cyanamides are very unstable bodies, and, with the elimination of NH_2, very easily condense into imido-nitriles. If, then, the force holding the cyanalcohols composing living proteid together were suddenly withdrawn, changes would rapidly occur in these unstable bodies with the formation of some acid and different cyanamides. The lowest cyanalcohols would condense to form lactic acid, carbonic acid, and ammonia; the latter combining with the higher cyanalcohols to form cyanamides, which would undergo condensation in the manner described by Tiemann. Some clue to the phenomena of rigor mortis and coagulation of the blood might be afforded by such considerations.

ON SOME

MODERN REMEDIES IN HEART DISEASE.

BY A. ERNEST SANSOM, M.D. LOND., F.R.C.P.,

PHYSICIAN TO THE LONDON HOSPITAL, CONSULTING PHYSICIAN TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN, LECTURER ON MEDICAL JURISPRUDENCE AND PUBLIC HEALTH AT THE LONDON HOSPITAL MEDICAL COLLEGE, ETC.

(*Concluded from p. 583.*)

II.—MITRAL STENOSIS.

IT is a matter of common experience that in mitral stenosis, just as in mitral regurgitation, compensation may be so effective that the subjects may for years manifest no symptoms to suggest the existence of cardiac disease. One point I must call attention to, as it indicates a discrepancy between different observers. Dr. Broadbent says that in mitral stenosis, according to his experience, "the pulse is almost invariably regular until the heart is obviously failing, unless the obstruction is complicated by regurgitation, or by valvular affection of the right side of the heart, or by intercurrent pulmonary affections." Dr. Broadbent is so good an observer, and my conclusions are so generally in accord with his own, that I should hesitate long before expressing a contrary opinion, but my experience of a large number of cases on this point is very decided. I have found that whilst in the early stages of mitral regurgitation, and until the right heart has become obviously dilated, or unless some complication has occurred, the pulse is regular, in mitral stenosis, though there are some exceptions, it is usual to find irregularities even in the very earliest stages, and when compensation is to all intents perfect. Such irregularity is seen in the sphygmogram as a repeated pulsation recorded in the down-stroke before the base-line is reached. I have so repeatedly seen this phenomenon that I have said, when one observes it in a case in which serious cardiac symptoms do not exist, mitral stenosis should be suspected. Moreover, it seems that such disturbance of rhythm is *primâ facie* probable when one considers the mechanical impediment to the due performance of the function of the left auricle. When in mitral stenosis compensation manifestly fails, the signs and symptoms are even more serious than in mitral regurgitation; the gradual oncome of dropsy is exceptional, but dyspnœa is very severe, pulmonary complications are more violent, and the venous engorgement of viscera, especially of the liver, is more pronounced. It must, moreover, be borne in mind that the physical conditions which result from mitral stenosis differ very considerably from those which attend mitral regurgitation. In mitral stenosis the left ventricle is not dilated, nor hypertrophied, nor of necessity physically altered; the right cavities, on the other hand, are engorged and dilated, and there is an increasing tendency to regurgitation through the tricuspid orifice; the left auricle is over-full on account of the obstruction in front of it, its cavity is dilated, and its muscle either hypertrophied or wasted. I have seen the muscular wall of the left auricle in one case as thick as that of a normal right ventricle, and in another as thin as a visiting card and containing no adequate muscle fibre at all. From these considerations it follows that in mitral stenosis the requisites for a restoration of compensation are an enhanced power of the right ventricle, whereby the blood may be driven through the lung into the left auricle, and a firm-walled and adequately muscular left auricle, allowing sufficient tension within its cavity and sufficient muscular contractility to drive the blood through the obstructed orifice into the ventricle. Whilst, therefore, in regurgitation there is a call upon us to increase the force of the muscles of *both* ventricles, in stenosis the necessity is to increase the force of the *right*. It does not follow that the problem is easier of fulfilment in the latter case; it is sufficient for us at the present that the conditions are not identical. We will now inquire as to the efficiency of special drugs in promoting compensatory action in mitral stenosis.

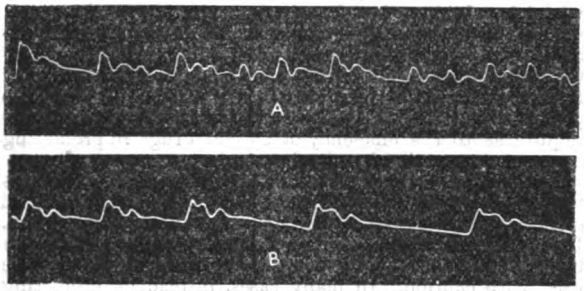
1. *Digitalis.*—It is a matter of experience with others as well as with myself that digitalis may not be given in mitral stenosis with the same advantage as in mitral regurgitation. It may often do good if given for periods of a week, with intervals of at least equal length, but it should always be used with caution. In many cases, instead of promoting regularity of the heart's action, it notably increases irregularity. On this point I entirely concur with Dr. Broadbent.[1] The search, therefore, for a more satisfactory therapeutic agent in such cases is very desirable. We will proceed to examine the evidence in the cases treated by—

2. *Convallaria Majalis.*—We will consider first the effect on excretion of urine as shown in the following table:—

TABLE V.—*Showing daily amounts of Urine, in ounces, in cases of Mitral Stenosis, treated by Convallaria Majalis.*

Case.	Before convallaria.	During convallaria.	After convallaria.
1	60>30<61>15>30	31<52>28<66>50>30	—
2	—	20, 15<55>40<90>80<115>100>50>4	14<34<42<92
2a	Readministration	85<115>75	85>65
3	—	28<40>25<52>20<28>20	20>16<30>20
4	22<35>25	22, 38>35>25	25<40, 50>25, 30
5	—	20<42>28<60>34	—

It will be observed that in these cases of mitral stenosis convallaria exercised a pronounced diuretic effect. In all cases the quantity of urine was augmented during its administration. The influence is markedly shown in Case 2, wherein the daily amount excreted rose from 20 to 115 ounces, and on readministration from 85 to 115 ounces. After the maximum diuresis in this case there was a very scanty excretion—4 ounces. In most of the cases there was no oliguria at the end of the treatment, but the evidence here, as well as that in the cases of mitral regurgitation, renders it probable that the drug may, after the maintenance of a maximum blood-pressure in the renal arterioles, so constrict these as to impede the blood-supply. It will be well, therefore, with convallaria, as with digitalis, to suspend the administration at intervals. It is a fair conclusion that convallaria is an important diuretic in cases of mitral stenosis, comparable in its effects with caffeine in mitral regurgitation, and that its effects in this direction are more pronounced in the obstructive than in the regurgitant lesion. We will now consider the cases of mitral stenosis in reference to the



Effects of convallaria on the pulse and respiration.—In one case the pulse-rate progressively fell under ten-grain doses of the convallaria extract from 112 to 80, 76 and 72, and after suspension of the drug rose to 92, to again fall under digitalis to 70. In another case the pulse-rate which under ten-minim doses of tincture of digitalis had increased from 99 to 110, decreased under convallaria to 102 and 64, rising after the suspension of the drug to 72 and 120. The sphygmographic evidence is more valuable and more conclusive than the mere observation of the rate of the pulse. In a third case in which the conditions were very severe,

[1] Cf. "Mitral Stenosis," International Journal of Medical Science, January, 1886, p. 85.

Digitized by Google

there being tricuspid regurgitation with pulsating liver, the extreme irregularity of the heart was greatly altered for the better. The sphygmogram taken in the early period shows great irregularity and full dicrotism (Fig. 4, A); the second trace, taken after convallaria extract (ten-minim doses) for thirteen days, and tincture of digitalis for a subsequent thirteen days, shows a slow and almost regular pulse of fair tension (Fig. 4, B). The increase of

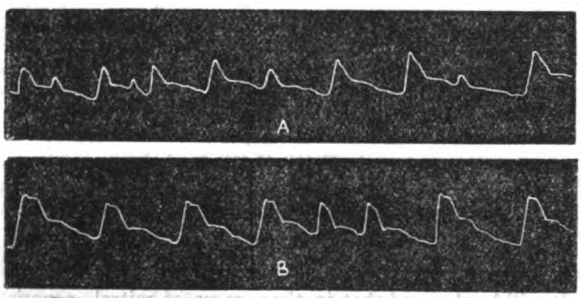


FIG. 4.

Sphygmograms in a case of mitral stenosis and regurgitation, with tricuspid regurgitation, treated by extract of convallaria, and subsequently digitalis. A, Before treatment; B, after treatment.

arterial tension is well shown in another series of sphygmograms. Before the administration of convallaria the trace shows a scarcely perceptible tidal wave; there is great irregularity in time and volume, and there are frequent repetitions of the systole shown in the downward-sloping portions (Fig. 5, A). After six days, tincture of convallaria

FIG. 5.

Sphygmograms in a case of mitral stenosis. A, Before the administration; B, after six days' treatment by twenty minims of tincture of convallaria taken three times a day.

in twenty-minim doses being administered three times a day, the tidal wave is seen to be much more marked, the summit of the trace being broadened, and there is much less irregularity (Fig. 5, B). The breathing was improved under the drug in nearly all the cases; in one case there was severe dyspnœa, which lasted during a fortnight (in this case bronchitis and emphysema existed in marked degree), but afterwards there was gradual improvement, and the patient left the hospital free from all distressing symptoms. It was evident that in these cases the drug acted very favourably. Only one case died in hospital; in this pericarditis and severe pulmonary complications were manifested; the patient improved during the time that convallaria was administered, and the temperature was reduced from 101° to normal, but after the omission of the convallaria the temperature rose to 108°; the patient died suddenly after having for a time considerably improved.

So far as I have been able to judge, convallaria compares favourably with caffeine in the treatment of mitral stenosis. In one case a girl, aged seventeen, in whom there existed tricuspid regurgitation in addition to mitral stenosis and regurgitation, the quantity of urine rose from a maximum of 30 oz. before the administration of caffeine to a maximum of 50 oz. during its administration, and on re-administration from 30 oz. to 54 oz.; but in regard to the pulse and respiration there was no perceptible influence. In another case of stenosis with œdema, the daily urine rose only from 36 oz. to 40 oz., and here also the pulse and respiration were not perceptibly influenced; the patient died. I was not encouraged to repeat the treatment by caffeine in the cases of mitral stenosis whilst I obtained such good results with convallaria; but in cases of this affection manifesting œdema or ascites, where a diuretic effect could not readily be obtained by convallaria, I should administer caffeine in addition.

My general conclusions are that caffeine is an agent of great value in the treatment of cases of mitral regurgitation, especially those in which there is much dropsy; and that convallaria, though manifesting no very favourable influence in cases of mitral regurgitation, except as an occasional substitute for digitalis, is of considerable therapeutic importance in mitral stenosis.

THE ANTISEPTIC TREATMENT OF WOUNDS.

BY SURGEON-MAJOR W. GRAY,
SENIOR SURGEON, JAMSETJEE JEJEEBHOY HOSPITAL, AND PROFESSOR OF SURGERY, GRANT MEDICAL COLLEGE, BOMBAY.

(*Concluded from page 534.*)

CASE 23.—Male, aged twenty-five. Amputation through left knee-joint for railway smash of the leg. Operation, Jan. 10th, 1884. Dressings as before. No rise of temperature. Stump opened up on the seventh day. Firm union. Patient discharged well on Feb. 9th.

CASE 24.—Male, aged thirty-five. Amputation below right knee for local traumatic gangrene (dry). Operation, Jan. 22nd. Dressed as before, except that several thicknesses of boric lint were used instead of cotton, the first layer being wrung out of the sublimate solution. No rise of temperature. Dressings removed on the seventh day. Good union. Patient discharged well on Feb. 9th.

CASE 25.—Male, aged twenty. Amputation above right wrist for machinery crush of the hand. Operation, Jan. 28th. Dressings as in preceding case. Temperature rising, they were taken off on the fifth day, when suppuration was seen to have occurred. This extended up the limb nearly to the elbow. Patient made a good recovery, however, and was discharged well on March 5th. This amputation was done at night; the injured limb was very dirty and difficult to clean, and the tendons were much "pulled." It is probable therefore that the parts had not been sufficiently purified before applying the dressing; hence its failure.

CASE 26.—Male, aged twenty-two. Amputation at middle of left arm for sarcoma of the forearm. Operation, March 8th.

CASE 27.—Male, aged twenty-two. Amputation at upper third of right forearm for machinery crush. Operation, May 9th.

CASE 28.—Male, aged fifty-two. Amputation just below left knee for mycetoma of foot. Operation, May 9th.

CASE 29.—Male, aged forty. Amputation at middle of left leg for papillomatous growth affecting the stump of a former Syme's amputation, performed for gangrene following snake-bite. Operation, May 16th.

CASE 30.—Male, aged thirty. Amputation at middle of left leg for spontaneous gangrene of the foot. Operation, May 28th.

CASE 31.—Male, aged thirty-five. Secondary amputation just below right elbow for machinery crush. Operation, June 6th.

The dressings in these six cases were alike. The stump was washed with sublimate solution, was then enveloped in a thick layer of dry boric cotton sprinkled with iodoform, over this more cotton, then oakum, and lastly a bandage tightly applied. No waterproof nor elastic band was used, as it was thought possible that some of the failures amongst the earlier cases were due to the retention of so much moisture around the stump. This omission was fully justified by the results, the flaps in every case having united by first intention and the stumps healing without a trace of suppuration. The dressings were quite dry and clean when removed. The patients were respectively discharged well on March 22nd, June 2nd, June 21st, June 3rd, June 13th, and July 2nd.

CASE 32.—Male, aged eighteen. Amputation at middle of left thigh for traumatic gangrene following a tramcar smash of the leg and knee. Operation, June 21st. Dressing as last described. The condition of the tissues, especially part of the anterior flap, was not altogether satisfactory.

Digitized by Google

Temperature rising, the dressings were partly taken off on the third day, when some inflammation was seen to be in progress, with considerable serous discharge. The wet dressing was removed, the wound cleansed, and fresh cotton was applied, as at first. This remained undisturbed for six days longer, and on removal the flaps were found fairly well united. A little sweet pus exuded from the drainage-tube. The patient was excessively restless and troublesome, with the result that a day or two later the flaps separated to a slight extent, causing considerable delay in the healing process. He eventually did well, and was discharged cured on Sept. 13th.

CASE 33.—Female, aged thirty-six. Amputation at middle of left arm for advanced disease of elbow-joint. Operation, June 26th.

CASE 34.—Male, aged twenty-eight. Amputation at middle of left forearm for machinery crush of hand and wrist. Operation, July 15th. Dressings as before. Results perfect in each case. Union by first intention.

In the latter case no sublimate solution was used, the face of the stump previous to closure being merely wiped dry with a purified sponge. Patients discharged well on Aug. 7th and July 28th respectively.

CASE 35.—Male, aged thirty. Amputation at middle of left thigh for disease of the knee-joint. Operation, Aug. 24th. Patient very anæmic and emaciated, also phthisical. Dressings as before, including sublimate solution. Removed on the eighth day, when fair union was found. The stump healed well, without suppuration, and the patient left hospital, much improved in general health, on October 10th.

CASE 36.—Male, aged sixty. Amputation at middle of right arm for disease of the elbow-joint. Operation, Sept. 20th. No sublimate solution used in this case. The surface of the flaps was first dusted with iodoform, and the dressing then completed as before. The temperature rising; on the sixth day the stump was exposed, when the flaps were found separated and their tissues distended with blood; no sign of putrefaction, however. The blood was cleared out, additional drainage-tubes were inserted, and the parts were redressed with iodoform and dry wood-wool. Three days later a slight erysipelatous blush was noticed about the shoulder, but it soon disappeared. The swelling of the flaps quickly subsided, and by the fifteenth day union, without suppuration, was complete. Patient discharged well on Oct. 10th.

CASE 37.—Male, aged twenty-two. Amputation at middle of left leg for spontaneous gangrene of the foot. Operation, Oct. 7th. Dressing: sublimate solution, iodoform, and boric cotton. Result perfect; union by first intention. Patient discharged well on Oct. 23rd.

CASE 38.—Male, aged twenty-five. Amputation at middle of right leg for chronic ulcer and deformity. Operation, Oct. 19th. No antiseptic lotion was employed in this case. The dressing consisted of dry absorbent cotton, dusted with salicylic acid, and the usual oakum and bandage. Union, without suppuration, was complete in twelve days. The salicylic acid in the cotton, however, caused severe excoriation of the skin with which it came into contact, and this, together with a subsequent attack of intermittent fever, delayed the patient's discharge from hospital till Dec. 17th.

CASE 39.—Male, aged twenty-eight. Amputation of right index and middle fingers for machinery crush. Operation, Oct. 27th.

CASE 40.—Male, aged fifty. Disarticulation at left knee for senile gangrene of the foot. Operation, Nov. 1st.

CASE 41.—Male, aged thirty. Amputation below left knee for mycetoma. Operation, Dec. 13th.

Dressings as already described, including sublimate lotion. Union by first intention in each case. Patients discharged cured on Nov. 21st, Dec. 8th, and Jan. 3rd, 1885, respectively.

CASE 42.—Male, aged eighteen. Amputation at lower third of right leg for mycetoma. Operation, Dec. 18th. The stump was washed with sublimate lotion, and after being sutured and dried was thrust into a long narrow bag half filled with dry wood-wool sprinkled with iodoform. While the bag was held against the face of the stump the leg was packed round with additional wood-wool, and the whole was then firmly fixed in its place with bandage and adhesive plaster. The result here was quite as successful as in previous cases; the flaps united by first intention, without a trace of suppuration. Patient discharged well on Jan. 22nd, 1885.

It will not fail to be noticed how much larger has been the proportion of successful cases in the latter half of the series, as compared with those of the first, and this greater success appears to coincide substantially with the disuse of the waterproof covering, and with the adoption of drier and thicker absorbent dressing. Accurate adaptation of the flaps I regard as of great importance. I now always mark them out with a scalpel, in order to ensure evenly cut edges, and when the skin has retracted they are completed by transfixion in the usual way. My experience has taught me, too, that antiseptic applications direct to the wound are in many cases unnecessary. I allude especially to those cases where the tissues are perfectly healthy. Still they do no harm, and, by way of making "assurance doubly sure," may be employed in every instance. All I mean to convey, however, is that we can in a certain class of cases obtain as good results without as with them, provided we attend carefully to other precautions. I never under any circumstances use the spray. Moisture in any shape or form I look upon as one of the most fertile sources of failure. Our whole efforts should be directed to preserving both the wound and the dressing in the driest condition possible. The essentials, then, of my present procedure are cleanliness, infrequent dry dressing, free drainage, accurate adaptation of flaps, and rest. Under the last mentioned, pressure by means of bandages may be included. To prevent putrefaction of bloody or serous discharge I prefer to have the dressing medicated with some unirritating stable material. Of all I have tried, boracic acid or iodoform is decidedly the best. The latter is the more expensive, however; hence I have found boric cotton more convenient to use. In order to press the flaps well together, and thus lessen or avoid exudation, I draw the bandage as tight as possible; the thick elastic pad of cotton and oakum underneath will always prevent it from being drawn too tight. So effectually does this answer its purpose that I have on more than one occasion found the original dressing, on first exposing the stump, almost perfectly dry and clean. Oakum, besides being more or less antiseptic, keeps the cotton together, and enables us to save the use of the latter to a certain extent as well. Wood-wool, although a most excellent absorbent dressing in suitable cases, is somewhat unmanageable in amputations. Made into pads, it does not fit closely enough; and employed loose, it is difficult to apply, and is inclined to get lumpy or become displaced. To ensure complete rest of the parts while the healing process goes on, the limb, if it be a lower one, is fixed in a heavy box splint and well packed round with cotton. Should the upper limb be operated on, the stump is securely fastened to the side of the trunk, with plenty of cotton interposed and placed around. The cotton packing, as well as the thick dry dressing, preserves the normal heat of the parts, a matter which I believe is essential to rapid and perfect union. Lowering of the temperature by wet dressing, exposure, or cold applications tends, I am convinced, to delay or prevent union by first intention. During the progress of the case the thermometer is used morning and evening; if the temperature remains normal, or does not rise beyond 99·5° F. occasionally, all is going on well, and the original dressing need not be disturbed sooner than the ninth or tenth day. When removed the flaps will be found firmly united. The drainage-tube may now be withdrawn, its track gently syringed out with carbolic or sublimate lotion, a little iodoform introduced, and the stump redressed with oiled lint or with boric cotton, taking care to sprinkle either with iodoform. Some of the unsoiled boric cotton from the original dressing will do quite well enough. A pad of oakum and a bandage complete the second dressing. This may remain on for four or five days longer, and when removed the track of the drainage-tube will have closed. The sutures may now be taken out, the stump being practically healed. Should the temperature, during the course of the second or third day, rise to 100° or beyond, and remain so, the antiseptic dressing has probably failed and must be removed, the stump being treated in the ordinary way, or, better still, with wood-wool and iodoform. Before doing this I always administer quinine, as the fever may be of malarial origin, and not traumatic. In more than one instance this has proved to be the case. The precaution I note here is, however, scarcely necessary, except in a climate where malaria prevails.

This paper has run on to such a length that I can hardly do more than mention that the treatment, on the same principles, of other surgical and of accidental wounds has met with nearly equal success. In the former class of cases,

Digitized by Google

especially where there is much areolar tissue—say, the axilla after removal of a large tumour,—the surface, after bleeding has quite ceased, is well rubbed over with iodoform, closed, and dressed with boric cotton and oakum, as described above, and the result is all that can be desired. In the operation for the radical cure of hernia, or after herniotomy, this treatment of the wound has been attended with remarkable success, union by first intention being the rule. Accidental lacerated and incised wounds are first thoroughly cleansed with carbolic lotion, then washed with sublimate lotion, iodoform is rubbed in, and the dry dressing, either boric cotton or wood-wool, applied. Sutures are not used, no matter how widely the wound may gape. The first dressing may be left on for twelve or fifteen days, or even longer, provided the temperature keeps down. In compound fractures the preliminary cleansing must be very carefully done before the sublimate lotion and iodoform are applied. The latter lotion should be forcibly injected with a syringe into every crevice of the wound. I find that for this purpose a Higginson's enema syringe is the most convenient; a continuous stream of lotion may be easily sent by it up the sheath of a tendon or, in case of amputations, between the flaps after the sutures have been inserted. The dry dressing in compound fractures requires to be very thick and to be bound on firmly; the limb is afterwards fixed on the appropriate splint. Small or clean-cut wounds under this method of treatment will be found closed on removal of the dressing, and larger ones with a healthy granulating surface.

Further experience will doubtless lead to modifications in the mode of dressing wounds I at present employ, and I think the tendency will be towards greater simplicity. When I first began I adopted most elaborate precautions as regards the disinfection of every instrument and material used in the operation; but as time went on I gradually discarded these one after the other; while my results, so far from suffering, became, on the contrary, better and better. I have come to the conclusion, therefore, that very many of the precautions we are advised to follow by writers on antiseptic surgery are wholly unnecessary, and that they are a hindrance rather than a help.

NOTES ON DIGESTIVE FERMENTS.

By WILLIAM MURRELL, M.D., F.R.C.P.,
LECTURER ON PHARMACOLOGY AND THERAPEUTICS AT THE WESTMINSTER HOSPITAL, EXAMINER IN THE UNIVERSITY OF EDINBURGH AND TO THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

II.—ON EXTRACT OF MALT IN THE TREATMENT OF WASTING DISEASES.

EXTRACT OF MALT is of such inestimable value in the treatment of all wasting diseases, both of adults and children, that any method which will help to secure the employment of good and reliable specimens must of necessity be of interest. There seems to be a general consensus of opinion as to its utility, but few people care to take the trouble to investigate its action or distinguish between good and bad preparations. That some extracts of malt are active whilst others possess little or no diastasic power is generally recognised. In the early part of last year, whilst a member of a Hospital Drug Committee, I had occasion to make some experiments on the subject, and certain results were arrived at which are, I think, of practical importance.

In examining comparatively different extracts of malt, it is of course essential that the investigation should in each case be carried out in exactly the same way. The slightest modification will introduce errors and nullify the result. In these observations I always used the same materials and the same apparatus. The experiments were made at the same time of the day, and as far as possible under identical circumstances. Nothing is more important in an inquiry of this kind than to record every step with the most minute detail. In the first place it should be stated that the specimens were one and all ordinary commercial articles—that is, they were bought at a shop, and were not selected samples obtained at an exhibition or from the manufacturer for the purpose of analysis. Precautions were taken to ascertain that they were not "old stock" which had been lying about exposed to alternations in temperature and other disturbing causes. They were probably all of comparatively recent manufacture, but on this point the evidence is not conclusive, as there is usually no date on the label or other indication as to when they were made. Those manufactured abroad may have been older than those prepared in this country, but I do not think this a point of any importance or could in any way invalidate the result. It is hardly necessary to say that care was taken to see that the bottles had not been tampered with, and that they were in their original wrappers or cases. The starch used in testing was always the same and came from the same stock. It was a pure white starch carefully dried. I purchased it for potato starch, but on examining it under the microscope and measuring the cells, came to the conclusion that it was Maranta arrowroot, an opinion which was confirmed by comparing it with known specimens, and with starch expressly prepared from potatoes. As will be presently seen, Maranta arrowroot is the best adapted for all comparative observations on the activity of extract of malt. The method of making the starch solution is of some importance. Ten grammes of the arrowroot were weighed out and mixed with a little cold water. This was then stirred into ten ounces of boiling water in a beaker over a gas burner. When the mixing was complete the beaker was removed from the flame and placed in a vessel of cold running water until the temperature fell to 40° C. It was kept constantly at this temperature during the remainder of the observation. It is not meant that the temperature was absolutely constant, but by careful watching it was found not difficult to prevent it from falling below 39° or rising above 41°. The quantity of extract of malt used in each experiment was one gramme. It was weighed out in a clean porcelain capsule, and after being mixed with a little water was poured into the starch decoction. The mode of testing was simple enough. Twelve test-tubes were arranged side by side in a rack, and each was filled about two-thirds full with distilled water, to which was added a drop of tincture of iodine, made according to the following formula: iodine, two parts; iodide of potassium, four parts; water, 250 parts. The drop of tincture of iodine falls to the bottom of the tube, leaving the upper part colourless. Every five minutes, and towards the end of the experiment every two minutes, a drop of the starch and malt mixture was taken up by a clean glass pipette and allowed to drop into one of the test-tubes, which was then inverted for a moment and replaced in the rack. At first, of course, a blue colour was produced—the starch reaction. Then, after a time, the time varying with the activity of the malt, the blue gave place to purple and the dextrine reaction was obtained. After a time, again, this ceased to appear, and the solution remained colourless, or, at the most, assumed a faint yellow tinge, indicating that all the starch had been converted into maltose. It is a little difficult to decide at what moment exactly the colour goes, but if the observations are always conducted by the same individual in exactly the same way and by the same light the error of observation cannot be very great. There is another method of judging the colour by throwing a drop of each solution on a white porcelain plate and allowing them to run together. I tried this plan, but do not think it better than the method described. By the test-tube plan one has the advantage of looking down on a column of liquid, so that even a slight tinge is readily appreciated.

There are certain precautions which must be taken to ensure good and reliable results. For example, it must not be supposed that the quality of starch employed in conducting these investigations is a matter of indifference; in fact very much depends on the starch. Starch bought in the shops is commonly adulterated, and is often artificially coloured with indigo, carmine, and other materials. It is obvious that the presence of a chemical substance would interfere with or perhaps even destroy a body so susceptible to the action of external influences as diastase. Even apart from the question of adulteration, the kind of starch makes a great deal of difference. On one occasion I was trying some extract with a new specimen of starch, and was much surprised at getting very little action. I knew the malt was not destitute of activity, for I had previously tested it with the arrowroot starch. I microscoped the new specimen, and found that it was maize starch. This led to a comparative examination of the two kinds of starch, and I found that an extract of malt which would convert into maltose a certain quantity of arrowroot starch in eight minutes took forty minutes to transform the same quantity of maize starch.

Digitized by Google

This induced me to try different varieties of arrowroot. I obtained authentic specimens of Bermuda Maranta arrowroot, of Canna arrowroot or tous-les-mois, and of Natal arrowroot, and found that they were all acted on by the extract of malt in exactly the same time, there being no difference between them. The next observation was made with a pure potato starch prepared expressly for the purpose, and it was found that the extract of malt which took eight minutes to convert the arrowroot took ten and a half minutes to convert the potato starch. This same specimen of extract of malt took thirty minutes to convert the same quantity of a very fine and pure wheat starch, the identity of which was confirmed by microscopic examination. Maize starch with the same extract took forty minutes, and rice starch ninety-five minutes. The different starches may be arranged in order as follows—

1. Bermuda Maranta arrowroot ...	8	minutes.
2. Canna arrowroot (tous-les-mois) ...	8	„
3. Natal arrowroot	8	„
4. Potato starch...	10½	„
5. Wheat starch...	30	„
6. Maize starch	40	„
7. Rice starch	95	„

That this difference of solubility in different kinds of starch exists is, I think, not generally known. Its practical importance with regard to the question of infant feeding, especially in the treatment of wasting diseases, cannot be over-estimated. It is possible, too, that it might be utilised as a test to differentiate some forms of starch. The statements made in papers respecting the action of extract of malt on starch are obviously of little value unless the kind of starch employed is mentioned.

The temperature at which the observations are made is of course a matter of the utmost importance. An elevation of a few degrees makes an enormous difference in the results. These observations, as already stated, were made at 40° C. It would, perhaps, have been better to have fixed on 38° as being nearer the temperature of the body, but practically 40° is very convenient. The thermometer was suspended in the fluid, which was frequently agitated. Had the observations been made at, say, 60° C., very different results would have been obtained.

There is a little point in connexion with the iodine test to which it is necessary to pay attention. The water in the test-tube must be cold. On one occasion, by accident, I used warm distilled water as it came from the still, and to my astonishment found that it gave no reaction with the starch. If the blue reaction be obtained with cold water, it disappears on warming the test-tube. Whether it returns on allowing the liquid to cool depends on the quantity of the reagents employed. If a very dark colour were produced, it would return on cooling; but if the colour were a faint blue, it would not reappear, although the addition of a little more iodine would bring it back. The presence of alcohol in any quantity also interferes with the reaction; in fact, iodide of starch is a most unstable body, even if it be a true chemical compound, which is doubtful.

I examined in all eleven specimens of extract of malt, the list including those most commonly used in this country, on the Continent, and in America. Of the eleven specimens there were only two which under the conditions I have indicated would transform *completely* all the starch in less than thirty minutes, and of these two one was more than three times as active as the other. Many of the specimens were of very poor quality and possessed little or no diastasic power. The extracts of malt usually supplied to hospitals are very poor in quality. At one institution I found that the committee was paying cheerfully £50 a year for an article which was not worth as many pence. It had evidently been concentrated in an open pan at a very high temperature. The colour of the extract is often said to be a good test of the quality; but it is not, for one of the best specimens I examined was very dark indeed. The liquid preparations were mostly poor; one, although it bore the name of extract of malt, was simply an ordinary beer and had little or no power of transforming starch. The presence of foreign substances is very common in inferior qualities of extract of malt. It is best to give the extract alone, and the addition of straw, chips, and sand is rarely an advantage. One preparation which was very fluid was examined for glycerine, but none was found; it had probably been taken out of the vacuum pan before the concentration was complete. On allowing it to stand for a few days, it gave off a peculiar odour and was evidently undergoing fermentation. It might be supposed that specimens of extract of malt would deteriorate by keeping, but I do not know that such is the case. Some specimens, on the contrary, seem to improve by keeping—a point which I have determined experimentally. For example, I examined a very good specimen, and found that it transformed a certain quantity of starch in twelve minutes and a half. A fortnight later I examined the same specimen under exactly the same conditions, and found that it accomplished the task in seven minutes. This improvement was probably due to a process of slow fermentation, in which more diastase was produced, or possibly a little lactic acid was formed, the presence of which in minute quantities is said to increase the activity of the ferment. It is a rule with some makers, I am told, to add a small quantity of salicylic acid to each bottle to prevent fermentation; but the custom is a bad one, for it impairs and ultimately arrests the action of the diastase on starch. It was thought well to examine a few specimens of malt-flour by the method already indicated. They were all active, but not equal in activity to the best extracts.

That the method described is not the best possible that could be devised I am quite prepared to admit, but it is the method best adapted to the requirements of busy medical practitioners. With complex apparatus and all the facilities of a chemical laboratory one might arrive at conclusions that might be more absolutely accurate, but for comparative purposes this simple method is reliable. As a proof of this I may mention that my colleague, Dr. Dupré, was kind enough to examine five of the best of these specimens very carefully, and he put them in the same order that I did. The clinical method is so simple and occupies so little time that every doctor should make his own examinations and assure himself that his patients are getting what he prescribes. If he will do this, he will find himself in possession of a powerful therapeutic agent and one of the best remedies for nearly all wasting diseases.

Weymouth-street, W.

ON THE TREATMENT OF SYPHILIS.

BY JAMES WILSON, M.D.

(*Concluded from page 586.*)

THE third and last indication in the treatment is that the inunction be carried out long enough. As our task consists in the healing of symptoms and as much as possible averting relapses, the earlier the syphilitic person is brought under mercurial treatment, the milder will be the course of the illness. The subject, therefore, of an induration should at once be placed under a course of mercury, the best form of which is the inunction, rather than wait for the setting in of secondary symptoms; if this is done the mysterious sting of the disease is broken off, and unquestionably the relapses are less in severity and appearance. In a case, therefore, of primary syphilis at least from forty to fifty rubbings should be given without a break. Nothing is more detrimental to the good effect of the mercury than a break, whether this arise from causes incidental to the mercury—such as mercurial diarrhœa, stomatitis, &c.—or dependent upon the patient himself; and nothing is more to be deprecated than the custom sometimes adopted of giving more ointment if inunction be employed, or calomel if the mercurial bath (of which I shall presently speak) be used, to make up for lost time, the result being that diarrhœa, colic, or some intercurrent mischief happens which may entirely prohibit any form of mercurial treatment being adopted, the very object being defeated that was hoped to have been gained. Generally speaking, after from seven to ten rubbings the good effects of the mercury begin to show themselves; there is now, perhaps, slight puffiness of the gums, which does not materially increase during a full course if the mouth-wash is steadily used, and seldom does the sponginess of the gums amount to more than slight uneasiness if the jaws are quickly snapped together or a hard crust be bitten. The only untoward incident I have noticed during the cure by inunction, where all goes well, is that patients sometimes complain of inability to sleep at night; they are restless, in no pain, but unable to get sleep. In such cases an opiate generally suffices to overcome the evil and effect the desired end. I

Digitized by Google

seldom stop the rubbings unless the irritability continue, or diarrhœa or some intercurrent trouble arise to preclude the continuance of the mercury. One of the first indications we have of the good effect of mercury is an increase in the body weight, which begins to show itself during convalescence and while the syphilitic poison is being eliminated through the various excretory organs of the body. This increase in weight is a point never to be lost sight of during a course of mercurial treatment, because when the normal weight of the body has been reached, or when the weight become stationary, there is no good in pushing the drug beyond eight or ten further rubbings if the inunction treatment is being employed, as we have attained all the good we are likely to get from the present use of the drug, and we had better wait for a little time before resorting again to treatment if only an inefficient course of treatment has been obtained.

Another point of importance after mercurial treatment, no matter whether internal or external, is the use of iodide of potassium in small doses, and entirely with the view of keeping up the good effects of the mercury, which it does in no small degree. A patient so treated, who has had an efficient course of rubbings in the manner that I have described, may of course develop subsequent symptoms, but unquestionably they will be less severe than when given by the mouth; and when the patient has had a full course of, say, from ninety to a hundred rubbings, whether taken at once (which is best) or at intervals, it is very exceptional to find him the subject of further relapses, at any rate for a long time, a period of immunity being afforded him for years, and possibly for life. Can we say this of the other forms of treatment? I think not. And I am sure, speaking from a large experience of cases treated in all climates and by all methods, as well as from the recorded testimony of some of the first syphilists in the world, that if the inunction treatment such as I have here advocated, and which I might perhaps, for want of a better term, call the "modern inunction treatment," were more resorted to in this country than it is, bad secondary and tertiary lesions of the viscera, bones, brain, and nervous system would be things almost unknown. I am aware that in private practice difficulties arise in carrying out the treatment efficiently, but difficulties arise in the treatment of all syphilitic patients. One of the greatest is the inherent prejudice (happily dying out, I am glad to say) of the use of mercury in any form; and I find patients readily submit to the inunction when told that it is the least injurious form of giving the drug. And the long-standing complaint against this method that it is dirty entirely dies out if the system I have advocated be carried out, which only allows of one portion of the body being anointed at a time, and this done thoroughly and efficiently.

Another useful form of administering mercury is the calomel bath, not, however, employing ordinary calomel for the purpose. This, where it is necessary (and the inhalation of the vapour is always to be encouraged, if possible, to the extent and manner hereafter described), is far too irritating. Mr. Henry Lee was the first, I believe, who called attention to this point and advocated the use of calomel which has been sublimed, thereby getting rid of any free hydrochloric acid and rendering the calomel vapour non-irritating and capable of inhalation without the least discomfort. Mr. Lee also, I think, was the first to call attention to the amount of water used in the preparation of the bath, and which is of the utmost importance, otherwise a sweating bath (if too much water is used) is produced, and not only is the very object defeated that was hoped to be gained, but a patient so treated is made infinitely worse and more debilitated. Then, again, the external covering to be worn while taking the bath must not only envelop the body and go round the whole apparatus, but must be made of such material that it will form a suitable night-dress for the patient. A most excellent covering for this purpose, made of moleskin, can be obtained from Mr. Lowe, of Stafford-street, Old Bond-street, London, who supplies the whole apparatus complete, including bath, &c., at a small cost. In this cloak there is a slit through which the vapour rises, passing in front of the face, so that a minute's inhalation of the vapour can easily be obtained as the vapour ascends; then by closing the slit in the cloak the further escape is prevented; upon drawing out the cane hoop which goes round the shoulder after the bath is finished, and tying the string round the neck, a complete night-dress is formed which has the additional advantage of allowing the mercury which has been deposited upon its interior being brought into contact with the skin, now rendered moist by the bath, and so perhaps allowing a further portion of the sublimed calomel to be absorbed. In general it is sufficient if the patient inhale for one minute in the five, the vapour thereby making three minutes as the full time for internal inhalation, supposing, as is usual, the bath takes about from fifteen to eighteen minutes for the complete disappearance of the calomel and water. Of course in affections of the mouth and throat longer time may be allowed. Patients can take these baths nightly without inconvenience. I have frequently prescribed from sixty to eighty without a break, and even a hundred; indeed, it is surprising, in this form of mercurial administration, to see the number of baths patients can take without causing the least disturbance to their systems and digestive organs, and with, I need scarcely say, benefit to their disease, provided the precautions above indicated are taken as to water and sublimed calomel. If this bath be used during the stage of efflorescence in a case of syphilis where inunction cannot be employed, and then the latter resorted to on the disappearance of these symptoms, we have, in my opinion, the most perfect form known at present of treating syphilis.

Lastly, there remains the hypodermic use of mercury and the modification of the Zittman treatment, in which no mercury is employed. As to the former, though not much resorted to in this country, it is extensively so on the Continent, and is unquestionably a very valuable form of administering the drug when it is desired to get the system rapidly under the influence of mercury; and I know no better form than one-sixteenth of a grain of the perchloride dissolved in about twenty-five minims of distilled water, and given daily in two injections, to which five minims of glycerine have also been added. Great care must be taken in administering the injection, a sufficiently long needle being employed to allow of its point being well carried into the subcutaneous fat, otherwise what is almost certain to take place will be a troublesome slough, in this respect acting like chloroform &c.; and a part of the body should be chosen, such as the flank, where less pain is felt. As to the modified form of the Zittman treatment, in which no mercury is given, it appears suitable for cases where mercury cannot be given—such, for instance, as albuminuria, not having its origin in syphilis or dependent upon that disease, which, far from precluding, would probably necessitate the use of the drug in a very careful form. However, I cannot say that my experience of this mode of treatment is large, and what I have had is not sufficiently encouraging to say more than that I believe it often acts well as a stop-gap, but seldom effects a cure. Possibly patients may get immunity from further trouble for a little time who have gone through this treatment, but I should entertain grave doubts as to their being cured of the disease; and I should certainly never submit a patient to such a course of treatment if I could possibly employ any form of mercurial administration.

In conclusion, one word as to the use of iodide of potassium. Unquestionably this is a most valuable drug when regarded in its twofold light—viz., that of the employment in small doses to keep up the good effects of the mercury after a course of the latter, and to which I attach the greatest importance, or the use of large doses to procure its own and special action; and strong as are the advocates that it cannot be regarded as a curative agent, but simply remedial and temporary, it cannot but go hand in hand with mercury in the disease, and ought not, I think, be separated from this drug in the successful treatment of syphilis; sooner or later it is almost sure to be required, and there are times and seasons in the progress of this disease when its utility outweighs that of mercury, though I would not regard it as an ultimate curative agent in the same light as mercury. I do not purpose entering upon the heap of vegetable remedies and others advocated and now in use amongst the various tribes of the world. I can only regard them as adjuncts at the best; and even sarsaparilla, except in large doses, I have found useless as an adjunct.

ON the 29th ult. twenty-two persons were fined at Leicester for non-compliance with the Vaccination Acts. There are now in the town about 11,000 defaulters under the Acts not yet proceeded against, in addition to the several thousands who have been already dealt with.

ANOTHER CASE OF

CONVULSIONS DURING PREGNANCY TREATED SUCCESSFULLY BY SUB-CUTANEOUS INJECTIONS OF PILOCARPINE.

BY P. HORROCKS, M.D. LOND., B.Sc., M.R.C.P.,
ASSISTANT OBSTETRIC PHYSICIAN TO GUY'S HOSPITAL.

ON August 1st, 1885, I was called in consultation with Mr. Ryan (who was acting for Mr. Leftwich of Newcross) to see a patient in convulsions. She was twenty-three years of age, and single. When fifteen years of age she was in Guy's Hospital under Dr. Braxton Hicks, and was operated on for an imperforate hymen. Since then she has menstruated regularly until the end of October, 1884, when the menstrual flow ceased. She has had scarlet fever three times; also fits when a child. Has always suffered from pain and "weight" in the head. Twelve months ago she had a fit, during which she was unconscious two or three hours, and was very violent (hysteria?). She is subject to hysterical attacks. On July 29th she noticed that her legs were much swollen; she had a fit on this day and became unconscious. It was three days later that I saw her, when I found her unconscious and in strong convulsions; face bloated with œdema, and purple from congestion and semi-asphyxia; tongue severely bitten, and bloody foam issuing from the mouth; abdomen enlarged to the size of a nearly full-time pregnancy. On vaginal examination, which the patient struggled against as though she felt the pain, the os was scarcely at all dilated, but the cervix was softened throughout. The child's head could be felt through the anterior vaginal wall. Her night-dress was wet with urine; skin hot and dry. Fœtal heart sounds heard midway between the umbilicus and the left superior iliac spine. I injected the third of a grain of pilocarpine, and placed her in hot blankets. She had a fit at 6 P.M., and another as they were bringing her up to Guy's in a cab, at 9.30 P.M. On arrival she was still unconscious, and the tongue was more swollen.

At 12.30 A.M., on Aug. 2nd, I saw her again, when vaginal examination was resisted more strongly. The os was dilated to the size of a florin. Temperature 100·2°; pulse 120. Fœtal heart heard again in the same place. One-third of a grain of pilocarpine was injected. This did not cause sweating, and so at 1.15 a fresh solution was obtained and one-third of a grain was again injected. This acted well, and in a few minutes she began to sweat and presently was bathed in perspiration.—2.50 A.M.: Can be roused. Does not resist vaginal examination so much. No repetition of fits. Uterus contracting frequently. Cries out sometimes that she has a pain in the back (uterine). Is very restless.—3.45 A.M.: Membranes ruptured spontaneously.—4.15 A.M.: Head nearly touching perineum. Patient speaks rationally, but her tongue is so swollen that it is difficult to make out what she says. Pulse quick.—4.30 A.M.: About four ounces of highly albuminous urine drawn off by catheter.—4.50 A.M.: Child suddenly and rapidly born; quite blue; no effort at respiration; no pulsation in cord; no cardiac beat to be detected. Efforts to induce respiration were of no avail. The child was a small one for full term.—4.55 A.M.: Patient asleep and snoring. 12 noon: Patient rational. She has not the faintest recollection of anything that has occurred since July 29th. Temperature 98·8°. Vaginal douche of carbolic lotion employed. Urine drawn off by catheter; two-thirds albumen; no casts; loaded with urates on cooling.

Aug. 3rd.—During the night she passed urine in bed. Temperature normal. No pain. Takes plenty of milk. Skin moist; tongue very sore; has headache.

4th.—Urine one-third albumen. Temperature 100·4°; headache.

From this time she rapidly got well, and in about ten days was up and about. She left the hospital on Aug. 16th with some albuminuria and headache. I have seen her several times since; the last time on Dec. 7th, when I examined the urine. It still contained a trace of albumen; no casts; sp. gr. 1015. She felt quite well and was again at her work.

In THE LANCET of June 13th, 1885, I published the notes of a case successfully treated by the subcutaneous injection of pilocarpine. The case I now publish is the only one I have had under my care since, and these two cases are the only ones I ever treated with pilocarpine at any time, and both have resulted very satisfactorily so far as the mother was concerned, but fatally to the child. Both these cases were very severe, as will be gathered from the clinical accounts. In both the cessation of the convulsions following the use of the pilocarpine was so quick and complete as to render it highly probable that the result was *propter* rather than merely *post*. An interesting point in the present case was the failure of the first solution used, owing to the fact that it had been made for some months. It not only failed to produce sweating, but the convulsions did not cease. After we had obtained a fresh solution and given an injection, the effect was quick, and there were no more convulsions. Obviously, therefore, in treating these cases by this method, a potent drug must be employed, and fortunately we are able to know whether it be potent or not by the presence or absence of profuse perspiration. If the patient does not begin to sweat within five minutes, the drug may be looked upon as useless, and a fresh solution obtained. Another point was the rapidity of the dilatation of the os, and the quick expulsion of the child after the administration of the pilocarpine. It would appear that pilocarpine must be looked upon as an ecbolic. The child was alive at 12.30, but when born, about four hours later, it was quite dead. Whether this was owing to the pilocarpine, or the convulsions, or the uterine contractions set up by the pilocarpine, or some other cause, must be left to future investigations.

GUY'S HOSPITAL.

A CASE OF HYDROPHOBIA; DEATH; NECROPSY; REMARKS.

(Under the care of Dr. HALE WHITE.)

THE following case adds another to those in which chloral hydrate in large amount, administered by the rectum, has failed to do more than relieve symptoms. At one time it was hoped that it would prove a valuable remedy, but like other drugs, such as curare, cannabis indica, aconite, &c., it has not fulfilled the high expectations which were formed of it. Pilocarpine is still *sub judice*, and will doubtless undergo a more extended trial. At present the medical world is watching with some anxiety and every wish for success the inoculation of patients with attenuated virus as carried out by M. Pasteur, hoping that a means may be found of curing or preventing the disease.

We are indebted for the following notes to Mr. H. V. Rake.

G. W——, aged sixty-three, was admitted on Sept. 18th, 1885, at 12 noon, for inability to take nourishment, and spasms on attempting to take fluids. The family and previous history are both very good. Three months ago he was bitten on the ulnar side of his right wrist by a dog, a half breed between a spaniel and a collie. Caustic was applied immediately by a chemist, and the wound healed well in a fortnight. On the 17th, at about 11 A.M., he began to feel poorly, and went to a doctor, who gave him some medicine. On the 18th, at 1 P.M., he found, on attempting to take medicine, that the effort threw him into a violent spasm, but he could take bread sop. This difficulty in taking fluids increased, so in the morning the patient called in a doctor, who advised him to go to the hospital.

On admission he could not at first be persuadad to drink, but at last he swallowed some milk and brandy, which action sent him into general spasms. Temperature 101°; pulse 90; respiration 34. He seemed to have read a good deal about hydrophobia. He had a wild look about his face, and was nervous and irritable. He suffered from spasms and shivering fits, apart from any drinking; during

Digitized by Google

one of these seizures he huddled himself up and turned away from the light, all the while making a noise not unlike whining. He was especially nervous in speaking, and during the act there was a good deal of hesitation. He could be considerably calmed if one reasoned with him. He spat about a good deal. He was placed in a quiet and darkened room, in which a steam kettle was placed, and was ordered an enema containing brandy, beef-tea, milk, and five drachms of syrup of chloral every four hours; he was also ordered subcutaneous injection of kinate of quinine, and also subcutaneous injections of hydrochlorate of morphia. At 4 P.M. he was quieter, did not have such frequent spasms, and ate a little biscuit with much less trouble than on admission. At 10 P.M. he wandered a little. During the spasms the abdomen became as hard as a board. He was not at all thirsty, and begged not to have drink forced upon him. When Dr. Hale White went to see him the first thing the patient asked was if it was raining.

Sept. 19th.—Has not slept much. He does not notice that it is raining, but he will not allow a damp towel near his face. The nurse says that, excepting from 3 to 4.30 A.M., the spasms have not been either numerous or severe, and that the patient has taken a little rice pudding and custard. During the morning he was fairly quiet, and could be persuaded to take a little food.—2 P.M.: The spasms have not been so frequent as yesterday. He is very hopeful of getting better. When he is talking to anyone he suddenly changes the subject. He takes food with less hesitation; when he attempts to drink there does not seem to be any actual spasm of the glottis. The pupils are not completely contracted by morphia.

20th.—1.30 A.M.: Took almost a saucerful of custard in teaspoonfuls; the act of swallowing is prolonged, and is accompanied by jerky inspirations; he is quite rational, talks well, and is not disturbed by the sound of water from a tap. He said he should like some tea, but the attempt to drink it produced some jerky inspirations, but ultimately he took a little with a spoon. He is very particular that anyone should wait till he is ready, when he will say, "Now we are right." A laryngoscopic examination showed the vocal cords were closed during inspiration.—5 A.M.: Has been sick several times, and has been very restless and talking actively. He thought he should like some tea, but he would not let the cup touch his lips. He tried to take a little in a spoon, but this brought on a violent spasm.—6 A.M.: Has vomited a good deal; his breathing is in short spasmodic gasps: skin covered with a cold sweat; is very restless, frequently moving the whole body.—7.50 A.M.: The patient quietly ceased breathing at this time. There was no special spasm or struggle before death. Has been unconscious for the last hour and a half.

The temperature during the whole of the illness showed a very decided tendency to rise. It was 101·4° on admission; shortly before death it was 101·4°; an hour afterwards, 102·2°; three hours afterwards, 98·2° in the rectum. Only three times was it normal, although it was taken hourly. It averaged about 100°. The pulse at first averaged about 100; for the last twelve hours of his illness it ranged from 108 to 124. The respiration averaged about 32, the highest being 38 and the lowest 26.

Treatment.—The patient had eleven fifty-grain doses of chloral per rectum, or 550 grains in all; twenty-five grains of kinate of quinine subcutaneously; and five grains of morphia. All this was administered during the forty-four hours he was in the hospital.

Necropsy.—The scar of the bite was examined carefully, but did not show anything abnormal. The median nerve was not implicated in it, nor was the ulnar. All the viscera were absolutely normal to the naked eye, except for some old pleural adhesions and some congestion and roughness on the inner surface of the trachea. Microscopically, the changes that have several times been described in the medulla were found here in that situation, and all in the upper part of the cord and in the pons.

Remarks by Dr. HALE WHITE.—The points of especial interest about the case are:—Firstly, the great difficulty of affecting the patient by even powerful drugs. It will be seen that he had enormous doses, but they were quite ineffectual. There was no sign of chloral poisoning from the large quantity of that drug, nor were the pupils contracted by the five grains of morphia given subcutaneously, nor could the temperature be kept normal with twenty-five grains of kinate of quinine administered subcutaneously. Secondly, is the important laryngeal observation, which shows that Dr. Pitt's views, as expressed in a recent number of the Guy's Hospital Reports, are correct. (For this observation I am indebted to Mr. Phillips, who, seizing a favourable opportunity, examined the patient.) Thirdly, there is the important corroboration of the corrections of the recent observations on hæmorrhage in the medulla. Fourthly, there is the redness and injection of the trachea, a feature so frequently seen in dogs that have died from hydrophobia.

NOTTINGHAM GENERAL HOSPITAL.

EXTRA-UTERINE FŒTATION; OPERATION; RECOVERY; REMARKS.

(Under the care of Mr. JOSEPH LITTLEWOOD.)

E. B——, aged thirty-seven, was admitted on May 16th, 1885, complaining of "enlargement of her bowels and flooding." She had been confined three times, and considered that she was nine months pregnant with her fourth child. She had felt fœtal movements up to the eighth month, when she had a severe fall, and since then had felt nothing. She had metrorrhagia of a week or ten days' duration at the end of the second month of gestation (Dr. Mutch states that she had an attack of peritonitis at or about that time), again at the end of the sixth month, and finally during the ninth month. On account of these attacks she consulted Dr. Mutch, and after the last attack was advised to go into the hospital. With the exception of these three attacks she has had no hæmorrhage during the last nine months.

On admission, the distension of the abdomen corresponded in size with an eight months' pregnancy, but was asymmetrical, bulging much more on the right side. In the left iliac region a second much smaller projection was noticed, which was afterwards proved to be the enlarged uterus. The larger swelling occupying the right side and middle of the abdomen, was fluctuating, and contained a solid mass floating in it. No fœtal heart or placental bruit could be heard, the fœtus having apparently died as a result of the fall at the end of the eighth month. On vaginal examination, the cervix uteri was found to be much displaced upwards and to the left; it was patent and admitted the finger as far as the internal os, which was closed, but not tightly. The sound passed without difficulty upwards and to the left a distance of four inches and a half. On bimanual examination, the cervix could be felt to be continuous with the mass in the left iliac region, which was therefore the fundus uteri. The uterus could be freely moved quite independently of the large cyst on the right side. She had not suffered any pain for the last nine months and experienced no inconvenience from the passage of the sound.

The following points were in favour of extra-uterine fœtation:—1. The fact that the woman, who had had several children before, was quite satisfied that she was pregnant, and that she had felt the fœtal movements up to the time of the fall at the end of the eighth month; and though she had been regular up to nine months ago, she had had amenorrhœa since, with the exception of three attacks of metrorrhagia. 2. That the swelling was fluctuating and contained a solid mass floating in it; the fœtal limbs could not, however, be felt through the abdominal wall. 3. The occurrence of uterine hæmorrhage, especially that at the ninth month, and the enlargement of the uterus.

For family reasons the patient left the hospital for two or three weeks and attended as an out-patient, when she was seen in the out-patient room and persuaded to return, and on the afternoon of July 13th the following operation was performed. The patient was put under the influence of bichloride of methylene and an abdominal section was commenced. The incision was made in the middle line and was about five inches long. There was no fluid in the peritoneal cavity, and the outside of the cyst, which was readily reached, was smooth, shining, and free from adhesions in front and at the side, and could not by its appearance be distinguished from an ovarian cystic tumour. It had several large vessels running on its surface. Spencer Wells's ovarian trocar was plunged into it, and a small quantity of coffee-coloured fluid escaped by the side of, but not through, the cannula; this was due to the smallness of the quantity, and possibly also to pushing the end of the cannula against the solid contents of the sac. On incising the walls of the cyst and introducing the hand, the limbs of a fœtus could be felt. It was removed without difficulty; it had evidently

Digitized by Google

been dead some weeks, and appeared to have been of about eight months' gestation. The umbilical cord was of a light-brown colour, and did not bleed on section, the circulation through it having evidently ceased for some time. It was not ascertained to what viscera the posterior wall of the cyst was adherent. The placenta was seen attached to the upper and back part of the sac, and was fixed. Slight traction was made on the placenta, but as this was quite fixed it was left *in situ*. The cyst wall, which was rather more than one-sixteenth of an inch thick, was stitched to the margins of the abdominal incision by a dozen or fourteen silk sutures. The cord was cut short and fixed at the lower part of the wound, which was closed up except at the lower part, where an indiarubber drainage-tube was inserted, the thickness of the ring finger. After the injection of one-sixth of a grain of morphia subcutaneously, the patient slept fairly well on the night of the operation, though there was a good deal of vomiting during that night and the succeeding day. No food was given for twenty-four hours following the operation, with the exception of a little ice. Temperature 99°; pulse 96; respiration 28.

July 15th.—Vomiting ceased; no pain; ordered veal broth and milk. Wound dressed; much thick dark-coloured discharge, some of which was got away by suction through the indiarubber drainage-tube.

16th.—Wound dressed again, and cavity syringed out with carbolic lotion (1 in 40).

During the next day or two, as there was carboluria, the lotion was changed from carbolic to Condy; the discharge was sometimes very offensive, and the wound was consequently dressed and the cavity syringed out several times a day. A week after the operation some shreds of what appeared to be the placenta began to come away, and on the seventeenth day from the operation a fairly large sloughing irregular mass was removed. The bowels were first moved by enema eight days after the operation, and continued to be moved in the same way afterwards, though there was some little trouble from old-standing piles. The wound has continued to discharge freely, and became free from fetor after the cord and remains of the placenta had sloughed away. She has had occasional rises of temperature, which have generally been followed by increased discharge for a day or two. She has passed from thirty to forty ounces of urine each day, and after the first week has not needed the catheter. She got up for the first time on August 4th, and, with the exception of a few days when she was not very well, has got up every day since. She now eats well and sleeps well, goes down into the garden every day, and is quite strong. There is still a sinus with a tube in it about two inches long, but the discharge is very scanty and quite sweet. She was kept in hospital for some time longer on account of the sinus which existed in the lower part of the wound, which, from its irregular contraction, kept back the discharge from the interior of the cyst and prevented rapid healing.

Remarks by Mr. LITTLEWOOD.—It will possibly be a matter of interest and speculation, but not of certainty, as to the form of gestation in this case. Tubal gestations generally burst before the third month, and a woman's only chance of recovery in such cases short of an operation, and that very quickly, is that the contents of the sac shall escape between the two layers of the broad ligament by rupture of the Fallopian tube at its lower margin, and little hæmorrhage take place; but these cases are, I believe, rare—i.e., where gestation goes longer than three months. Now, this cannot be said of the tubo-ovarian form; in this, arrest and development of the ovum may take place in the fimbriæ, the sac being formed partly out of the dilated mouth of the tube, and partly by attachments to the ovary and other structures near; in these cases gestation may go on until the full time or thereabouts; the fœtus may then die, and if the sac is a tough one the woman may carry the remains for years without any harm befalling her. Ovarian gestation has been doubted by many authorities, and the same may be said about abdominal gestation, except when it is secondary to tubal or tubo-ovarian, in which case the ovum after rupture of the sac preserves its vitality by retaining part of its original attachments. I am myself inclined to think that the balance of probabilities is in favour of the tubo-ovarian forms. I have reported this case (for the notes of which I am considerably indebted to my colleague, Dr. Handford, and the resident officers, Mr. Anderton and Mr. Ashwell) on account of the prolonged period of gestation, no similar case having occurred in my experience, the nearest approach to such being a case which, I have no doubt, will be remembered by some as occurring in the practice of Mr. Ellam and the late Mr. Thompson. A woman was supposed to be about six months pregnant, when her abdomen got gradually smaller, and she came to the conclusion that she had been mistaken. About eighteen months afterwards she had a good deal of irritability about the bladder. She passed urine frequently, which was found to contain much pus. She passed one day what seemed like a bit of bone, which led her to have her bladder examined, when there existed no doubt as to the cause of her trouble. I gave her chloroform. The urethra was slit up, and the bones of a fœtus, probably of six months' gestation, were removed from the bladder. I saw her a year or two afterwards, when she was in good health, but had difficulty in holding more than a small quantity of urine.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Supra-pubic Lithotomy.

AN additional meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair. The whole evening was devoted to the consideration of the subject of Supra-pubic Lithotomy.

Mr. RICHARD BARWELL read a paper on Supra-pubic Lithotomy. A not infrequent sequela of urethro- or vesico-vaginal lithotomy is an intractable form of vesico-vaginal fistula, of which several instances have been under the author's care; hence he rejected those methods in the following two cases:—Case 1: A girl aged nine, admitted into Charing-cross Hospital on Feb. 6th, 1885. She was greatly emaciated, and suffering from dribbling of urine and frequent micturition. A large vesical calculus was detected. On Feb. 12th, 3½oz. of boro-glyceride solution, all that the bladder would hold, were injected, and Mr. Morgan passed a finger per vaginam to steady the stone and to prevent escape of fluid from the bladder by compressing the urethra against the pubes. The skin and linea alba, and then the thin fascia transversalis, were incised. An exceedingly soft layer of fat separated the bladder from the abdominal wall; this was cautiously divided, the bladder opened, and the stone extracted. The peritoneum did not come into view until the escaped fluid allowed the bladder to contract; the wall of that viscus, as also the abdominal wall, was sewn, a drainage-tube being placed between the two. The child suffered nothing after the operation, and by Feb. 26th the wound had closed. The stone measured 2¼ in., 1½ in., and 1¼ in. in its several dimensions, and weighed 2½ oz. Case 2: A man aged sixty, but feeble and looking old, had frequent and copious hæmaturia, which was increased by the most delicate sounding; the prostate was enlarged. On sounding, a stone was found. Measurement in three directions gave 1⅛ in., ⅞ in., and ⅞ in.; but the condition of parts, and the possibility that a papilloma might also be in the bladder, induced Mr. Barwell to prefer supra-pubic lithotomy to either the perineal operation or lithotrity. On April 30th 16 oz. of boro-glyceride solution were injected and retained by tying a tape round the penis. The skin, linea alba, and transversalis fascia being incised, the lower fold of the peritoneum was found to lie about three quarters of an inch above the margin of the pubes. The membrane was pushed without the slightest resistance from the front of the bladder. The man suffered no pain after the operation; the wound healed quickly, save a sinus just above the pubes, from which urine oozed in small quantity, and which did not thoroughly heal till July, the man remaining well in health. The author pointed out that the high operation for stone had been too much neglected, and may well be used in cases other than those of exceptionally large stones. For children it is particularly well adapted, and he contended that for female children no other lithotomy should be practised. There was no danger of a permanent fistula, the case (No. 2) being, he believes, the longest persistence on record. The danger of urinary infiltration may be avoided with practical certainty by proper after-treatment. In a properly conducted operation the peritoneum is safe—injection of the bladder will always raise it

Digitized by Google

high enough; and as it is barely attached to that viscus it yields upward to the slightest touch of the finger. The author showed that distension of the rectum had a very small effect on the anterior peritoneal fold. He also pointed out that Petersen's experiments gave unreliable results, and that Garson's table in reality supported his (Mr. Barwell's) views, and he detailed (in an appendix) fourteen experiments of his own in proof of this contention.

Mr. WALTER RIVINGTON read notes of a case of Vesical Calculus of unusually large size removed by Supra-pubic Cystotomy. Thomas K——, aged sixty-one, entered the London Hospital on January 13th, 1885. For sixteen years he had been troubled with symptoms of calculus. On examination per rectum, a large, round, smooth swelling was detected in the situation of the prostate gland. No stone could be detected with a sound. On February 24th median urethrotomy for the purpose of exploration was performed, and it was ascertained that the hard mass was not connected with the prostate, and that the bladder wall was pressed over by it to the right side. A sound pushed far back into the bladder at length struck a stone, which proved almost immovable when grasped by forceps. Under these circumstances it was decided to open the bladder above the pubes. A staff was introduced into the bladder and the usual incision made above the pubes. The end of a stone was now detected projecting into the bladder through an opening posteriorly. It was grasped with forceps, but could not be moved. Lithotrites were useless. The stone was therefore broken up with a chisel and mallet and extracted piecemeal. After the extraction, the wound in the bladder and that in the soft parts were separately sutured, with insertion of a drainage-tube, and a silver tube was inserted into the perineal wound. The patient rallied well from the operation. The supra-pubic incision was reopened on the 28th, as there was evidence of the escape of urine through the bladder wound. The surface of the wound was sloughy, but gradually cleaned and filled up with granulations. On March 21st the patient was allowed to be up for an hour in a wheeled chair. On April 17th the opening into the bladder had closed by granulation, and, with the exception of a fistula in the perineum, the patient had now recovered from the operation, and was up daily. At the end of May, three months after the operation, he had a renewed attack of cystitis. His urine became ammoniacal, diarrhœa ensued, and he died on June 4th. Permission was only obtained to inspect the abdomen. Suppurative nephritis of the left kidney was found, with inflammation of the bladder and of the large pouch in which the stone had been lodged. After the operation the collected pieces of the calculus weighed 23 oz. avoirdupois. In its restored form it measures in circumference 13 in. by 10 in., in length 4¾ in., in width 3¼ in., and 3 in. in thickness, and weighs 22½ oz. It is mainly composed of lithic acid and lithates. Although not absolutely the largest calculus ever removed from the human bladder during life, it appears to be the largest removed during life with recovery of the patient from the immediate effects of the operation. The case stands alone as regards the inclusion of the calculus in a pouch, the difficulty of the operation, and the breaking up of the calculus before extraction.

Mr. JACOBSON contributed a case of Supra-pubic Lithotomy. A labourer, aged nineteen, was admitted into Guy's Hospital on Jan. 21st, 1886. He had suffered from constant irritability of the bladder all his life, with marked symptoms of stone for five years, and with cystitis for a year. The lithotrite and sound gave evidence of more than one stone. For this reason chiefly lithotomy was preferred to lithotrity. Hypogastric lithotomy was made use of on account of the age of the patient, the long duration of the symptoms, and the great probability that the kidneys were impaired. On Jan. 30th hypogastric lithotomy was performed, the bladder having been injected with 10 oz. of water and the rectal bag introduced. The peritoneum was not seen. One stone was readily found on incising the bladder, but prolonged search failed to find others. This was probably due to the mistake of keeping the bladder distended with fluid during the search, owing to which two other stones, small and light, escaped detection. Neither sutures in the bladder, nor drainage-tube in the wound, nor catheter in the urethra were made use of. The patient's recovery was somewhat retarded by an attack of pneumonia setting in the day after the operation. There was never any sign of extravasation or cellulitis. On the fourth and fifth days the wound and urine were distinctly ammoniacal, but this condition yielded to treatment. Two weeks after the operation a large venous hæmorrhage took place, and a few hours after a small calculus was removed from the wound; a few days later another and smaller calculus escaped. On the twenty-third day urine was first passed naturally; by the fifth week micturition was normal. It is evident now that, owing to the small size of the largest calculus (only 300 grains), all might have been dealt with by lithotrity. The author, however, still ventured to bring the case forward, and concluded with the following propositions: 1. That this operation has a future of revived usefulness before it; and that it will be found of great value by those who only have to deal with stone occasionally, and who find themselves face to face with stones of good size in adults. 2. That while as an operation it can never contrast with the rapid brilliancy of a lateral lithotomy, it will, in its improved form, give better results in adults with stones not suited to lithotrity. 3. That at present, till a larger number of cases of the improved operations have been collected, it will be wise not to attempt to close the bladder with stitches. 4. That in reviewing an abandoned operation the following questions call for an answer: Do we stand in a better position towards the operation than our predecessors did? This question can only be answered in the affirmative after the work done by Dr. Garson, Professor Petersen of Kiel, and Sir Henry Thompson. On what grounds was the operation abandoned? The grounds on which this operation was abandoned were enumerated.

Sir HENRY THOMPSON opened the discussion by remarking that the alteration in lithotrity, resulting from Bigelow's treatment, had changed the conditions under which lithotrity was now performed, and left a different category for those cases that required cutting. There could be no question that stones weighing 1½ oz. to 2 oz. could be removed safely by lithotrity. He thoroughly agreed with the expression of opinion that it was safer to adopt the supra-pubic operation, provided the modern improvements that belong to it were adopted. The operation could be performed in a more safe and easy manner than was formerly possible. The distension of the rectum was valuable, not only from the fact that, as Bouley strongly contended, the supra-pubic interval was increased, but from the circumstance that it places the bladder immobile under the surgeon's hand in the abdomen, and out of the pelvis. Hildamus, in the 17th century, had shown how it was possible to push up the stone above the margin of the pubes in children by pressure inside the rectum. The distension of the rectum was most valuable in the removal of large tumours of the bladder by the supra-pubic method; Sir Henry had operated upon two such tumours by this method. In nine cases in which he had performed the supra-pubic operation he had used but one ligature, the liability to hæmorrhage being very slight. But one case of the nine had died from advanced renal disease, a few days after the operation — an unavoidable complication. In the case of a tumour in a lady who was very anæmic, he also preferred the supra-pubic operation, as likely to be attended with the least hæmorrhage. He showed a simple flexible tube that he employed to allow the urine to flow off. The wound ought not to be closed for some days.—Mr. POLLOCK said he would like to ask the Fellows how far they would justify the supra-pubic operation. He related a case in which the two extremities of a hairpin had penetrated the posterior wall of the bladder, and a calculus of large size had formed round this foreign body. Here he made an incision into the posterior wall and removed the calculus and hairpin. After the cystitis subsided an ordinary vagino-vesical fistula remained, and was treated successfully after the ordinary fashion.—Dr. HEYWOOD SMITH related a somewhat similar case, in which, however, the incision healed by the first intention by sewing the edges of the fresh wound together after the primary operation was finished.—Mr. CADGE recommended caution in deducing general conclusions on insufficient facts. In the last century the operation had fallen into undeserved obloquy, but he was not sure that we ought yet to conclude that lateral operation might be abolished in favour of the new supra-pubic method. Many of the already reported cases might have been dealt with by the lateral operation, and Mr. Crichton of Dundee had shown that stones weighing from 4 oz. to 8 oz. might be successfully dealt with by the old operation. He thought it was not yet proved that the supra-pubic operation would interfere largely with the lateral method. He agreed with Mr. Barwell that distension of the rectum was not of much value in raising the prævesical fold of peritoneum, but that it was

Digitized by Google

mainly useful in raising the fundus of the bladder, which it could do even as much as 2 in. With the supra-pubic operation no stone should be left behind, a condition which was possible in the lateral method. The absence of hæmorrhage was another quoted advantage of the high operation, but in the dozen or so cases yet reported there had been three of decided hæmorrhage. Infiltration of urine, moreover, was not a common event in the lateral operation. In one case 18 oz. of fluid were injected into the rectal bag, on the removal of which a drachm of blood followed; in a day or so suppression of urine set in, and the patient died, advanced disease of the kidneys being found. At the necropsy a wound of the rectum between it and the bladder, going through the circular fibres of the muscular coat, was detected. It had done no great harm, but still the peril should be borne in mind.—Mr. R. W. PARKER had performed the supra-pubic operation once, and found it easy of performance. He had had twenty-two cases of stone, with the large proportion of eight females. In all these latter cases he rapidly dilated the urethra, and then removed the stone. He had had no death and no incontinence of urine following this procedure. His largest stone was rather smaller than that of the second of Mr. Barwell's cases. He exhibited the stones he had removed to show what could be done by the simple method.—Dr. GARSON said that Mr. Barwell's experiments had been made with the abdomen opened for four inches. His own were made with the abdomen unopened as well. The prævesical fold of peritoneum he found to be raised from 40 to 50 mm. After distending the bladder and the rectum, it was ascertained that for 5 centim. the bladder extended above the upper edge of the symphysis pubis. As the water was let out of the rectum the distance was reduced to 2½ centim. If the abdomen were opened first, but little, if any, raising of the peritoneal fold took place. Distension of the rectum first raises the bladder upwards and then forwards. In emptying the distended rectum the bladder describes a downward and backward course in a sort of curved line, so that what was uppermost became posterior.—Mr. T. BRYANT had repeated Dr. Garson's experiments and corroborated them in every way. The rectum was distended with 14 oz. first, and then the bladder with from 16 oz. to 20 oz., and in every instance he found that from 2 in. to 3 in. of the anterior wall of the bladder was exposed in the hypogastrium after making the usual incisions. He also added, with Mr. Cadge, a caution in thinking that evidence yet before the profession was not enough to justify any general conclusion on the utility and scope of the operation. Probably, however, in dealing with all large stones the supra-pubic operation was preferable to the lateral, especially if there be disease of the kidneys, though this complication would render any operation more perilous. He concurred with Mr. Parker in the opinion that in females rapid dilatation and lithotrity would prove sufficient for a large majority of stones.—Mr. LUND urged that in the lateral operation the danger arising from bruising of tissues made them unfavourable for healing; this was one difficulty that might be entirely disposed of by the supra-pubic method. The use of anæsthetics, he believed, was one reason why the operation might now be regarded with more favour than it was in the last century. In a case of piles for which the cautery had been used, the rectum became loaded with five days' accumulation; an enema was administered, and caused severe pain at the end of the penis; this, he thought, was explained by the distension exercising pressure on the sensitive neck of the bladder.—Mr. BARWELL said that his paper had been written before Sir Henry Thompson's lecture had appeared in THE LANCET, and before the *brochure* on the subject had appeared. He had performed experiments on the distension of the rectum so as to ascertain the exact position of the anterior fold of peritoneum as it would be in the surgical operation. He was surprised to find how little a safe degree of rectal distension raised the peritoneal fold. He did not think that in lithotomy there was any considerable use in having the base of the bladder brought nearer to the abdominal wound in the supra-pubic operation. No doubt there was a certain degree of danger in distending the rectum, especially in old people.—Mr. RIVINGTON said that he had removed a calculus measuring 6 in. by 5 in., and weighing 3 oz. by vaginal lithotomy, the wound healing almost completely by first intention. In another case, as in the President's, a hairpin had stuck in the anterior wall of the vagina and a calculus formed around it; here, also, he performed a similar operation. He should prefer vaginal lithotomy for most cases of the kind, unless the stone were of the very large kind.—Mr. JACOBSON considered that there would be no difficulty in detecting stones in future whilst exploring the bladder in the supra-pubic method. That he did not find all the stones in his case was not due to recesses formed on either side of the bladder in the rectum. It was dangerous to distend the rectum by anything more than 12 oz. or 14 oz. of fluid. In his own case some bloody mucus was passed for a day or two, but the distension had not been excessive. He concluded by expressing the opinion in the form of questions that the supra-pubic operation was preferable to the lateral.

CLINICAL SOCIETY OF LONDON.

Tubercular Ulceration of Palate.—Popliteal Aneurysm in Locomotor Ataxy cured by Pressure.—Acute Intestinal Obstruction after Ovariotomy.

AN ordinary meeting of this Society was held on the 26th ult., Mr. Thomas Bryant, F.R.C.S., President, in the chair.

Mr. CLUTTON read the notes of a case of Tubercular Ulceration of Palate, which was illustrated by drawings. The patient was a girl aged fifteen, who had been under his care about nine months. Her family history gave no evidence of a phthisical tendency. In her previous history it appeared that she had been in the Evelina Hospital for six months under Dr. Goodhart, who had described her condition in his book on Diseases of Children as a typical case of scrofula. In July, 1885, a year after leaving the Evelina Hospital, she was sent to Mr. Clutton at St. Thomas's Hospital by Dr. Rugg. The soft palate was then found to be divided by a median cleft, and the whole of the surrounding tissues swollen and superficially ulcerated. The surface was finely granular, and numerous small pit-like ulcers were distributed over the hard palate at a distance from the median fissure. The glands beneath the jaw were large and hard, as also were those in the left groin. The lungs, examined by Dr. Acland, were reported to be fairly healthy. During September the surface of the palate, previously ulcerated, almost entirely healed, but one auditory canal and the interior of the nose were found to be affected with a similar condition. In October the larynx was examined by Dr. Semon, when the epiglottis and arytenoid cartilages were seen to be ulcerated in the same manner. In November the lungs were found by Dr. Acland to have undergone a marked change, the right apex showing signs of active disease. The temperature, taken regularly about this time, recorded only a slight rise of the thermometer at night. In February of this year the palate had again broken down, and was occupied by three deeply cut ulcers. The right cheek also was now covered with scattered scaly papules, like the early stage of lupus. In March the lungs were found again to have improved, showing no distinct physical signs of disease. The palate also had again begun to heal. The secretions and small portions of the diseased surface were frequently examined by Dr. Acland and Mr. Ballance, but no bacilli were at any time found.—Mr. T. BRYANT had only seen two cases of lupus of the palate spreading to the larynx: one occurred in a well-to-do lady, in whom there was lupus on the nose and cheek; there were recurrences at long intervals, the tongue and epiglottis being involved after the palate; death took place from acute phthisis.—Dr. FELIX SEMON had seen Mr. Clutton's case. Was it lupus or tuberculosis? He approached the question from a clinical point of view. In September, 1885, there was no affection of the skin or lungs. Isambert of Paris had recorded the first case of faucial tuberculosis, and B. Fraenkel of Berlin followed him. In these cases of pharyngeal tuberculosis, tubercular affections of the lungs were sometimes present; in others totally absent. There was no reason why tubercle should not appear primarily in the mucous membrane. So far as he knew, however, there had been not a single satisfactory case recorded in which the larynx was primarily affected. He could not say from the clinical appearances whether a laryngeal disease were tubercular or lupoid, and the opinion of Schrötter and Stoerk confirmed him in this. But the temporary improvement of Mr. Clutton's case was in favour of the lupoid nature of the disease, and conflicted with the tubercular view taken by him (Dr. Semon) at first; then, after the skin had become affected the diagnosis seemed still more conclusive, and was made still more so by the spread into the nose and

Digitized by Google

œsophagus. He referred to the case of the lady shown that evening. From drawings of the early stage of the disease it appeared that there was a very close resemblance between that case and Mr. Clutton's. With regard to lupus of the larynx, Chiari and Riehl had collected in 1882 all the cases on record, and there were not more than thirty cases. But he questioned whether it was so excessively rare, and believed that if every case of lupus were carefully examined laryngoscopically lupus of the epiglottis might be found more commonly. As to the treatment of lupus of the larynx, there was only one case that had been cured, and that was Chiari's. The best result in all other cases has been a temporary improvement. In the case of the lady above mentioned aphonia had lasted a year, and there were very large mamillated excrescences; the case seemed most unfavourable, but the patient urged perseverance and now was almost cured; there had been no recurrence for five months.—Mr. DAVIES-COLLEY asked whether all the brothers and sisters had been examined with a view to exclude syphilis as far as possible. The girl had an affection of the eyes, some lumps on the forehead and back of the head, and an ulcer above the internal malleolus of one leg. He admitted that no great improvement of the condition of the soft palate took place under the use of perchloride of mercury, though the leg had improved. He had not seen another case in the active stage, but had seen three or four cases in which a cicatricial contraction of the pharynx had occurred, probably as the result of a similar process.—Mr. MALCOLM MORRIS related the case of the lady aged thirty-five shown that evening. Her disease began in 1867 with ulceration of the mucous membrane of one nostril. This did not advance much till 1876, when it spread outside and affected the upper gum and hard palate; treatment was begun in 1873 with various medicines—cod-liver-oil, iodide of potassium, and iodine. At the end of September, 1884, Mr. Morris first saw her, when there was very widespread disease. The importance of the diagnosis between lupus and tubercle was then discussed. A French observer had said that scraping or scarification of lupus was liable to be followed by tuberculosis of the lung, and argued that it was dangerous to touch lupus for this reason. Lupus was capable of inoculation in animals, and the bacilli of the two diseases were identical. Professor Raudnitz of Prague had collected 209 cases of lupus, and in only two was there tuberculosis of the lung, whilst in twenty-one there was a family history of tubercle. Though there did not appear to be much pathological distinction between lupus and tubercle, yet Mr. Morris thought there was a decided clinical difference. He had surgically treated about forty cases, and had never yet seen any tuberculosis of the lung follow. The slowness of the growth, and the fact that drugs had some influence on tubercle and no effect on true lupus, were clinical differences. Altogether he considered that the identity of lupus and tubercle had by no means been proved.—Dr. GLOVER related the case of a man whose palate was covered with small superficial, round, painful ulcers. He was admitted into Middlesex Hospital under the care of Dr. Douglas Powell; numerous bacilli were found in scrapings from the diseased parts; acute phthisis rapidly developed, and he died in six or eight weeks. There was no history or other indication of syphilis.—Mr. CLUTTON, in reply, said he had not seen the whole of the family; but two others of the nine presented no trace of syphilis. The swellings on the body were observed by Dr. Goodhart, who did not consider them as syphilitic. Rest in bed often caused great improvement in ulcers of the leg. Mr. Davies-Colley said the child had rested in bed.

Dr. LONGHURST read a case of Popliteal Aneurysm cured by Pressure, occurring in a patient aged fifty-one, the subject of locomotor ataxy. He was a single man of temperate habits, who for many years was an active member of the Alpine Club. There was a family tendency to varicose veins and phlebitis, in which the patient participated. He had had syphilis in 1860, and was treated by mercury; no secondary symptoms appeared, and his health remained good till 1878, when symptoms of tabes dorsalis set in. A voyage to the Cape of Good Hope in 1883 effected no improvement. Early in April, 1885, the popliteal aneurysm made its appearance, and he was then seen by the author. He had been able to attend to his duties as a solicitor, and had hunted three times a week with the Brighton harriers, but there was no history of a distinct strain or injury. On examination there was a pulsating swelling, the size of a small walnut, in the left popliteal space, without bruit, and completely controlled by pressure on the femoral in Scarpa's triangle. There was evident pulsation in the anterior and posterior tibial arteries at the ankle; the superficial veins of the limb were varicose; the limb was well nourished. Pulsation in the right popliteal was forcible, and the calibre of the vessel full. Cases of popliteal aneurysm in the subjects of locomotor ataxy not being very common, there was some uncertainty as to the best course of treatment to be pursued. Dr. Longhurst considered that pressure would be the best method of treatment, and Professor Humphry concurred in this view. Accordingly on April 19th treatment by pressure was commenced under the direction of Mr. Thomas Smith. Esmarch's bandage was applied from the foot upwards over the knee and retained for an hour and a half. Then the screw tourniquet was applied to the femoral artery and continued all day, when it was removed, the pressure having been well borne. On the evening of the next day a shot bag weighing 11¼ lb. was suspended from a cross bar over the bed so as to compress the femoral artery in Scarpa's triangle; pulsation was completely controlled. An extra pound was added at the end of an hour, and the whole borne till 11 P.M., when it was taken off for the night. It was reapplied on the 21st, and, alternately with Esmarch's bandage, was continued till 11 P.M., when pressure was again removed for the night. On the next day the same treatment was pursued. At the end of the day there was no pulsation in the aneurysm. The weight was reapplied on the 23rd at 7.15 A.M., but had to be removed at 10.30, because the foot was numb and cold. It was, however, intermittently employed till 7 P.M., and finally disused. There was no pulsation in the aneurysm, but it existed in the small arteries around the knee, and only in the anterior tibial at the ankle. At 10.30 P.M. the limb was enveloped in a calico bandage, but as the pressure prevented sleep it was taken off at midnight. There was no return of pulsation on the 24th. The aneurysm was thus cured by pressure in five days, neither the varicose state of the veins nor the nervous disease having interfered with the treatment. The shrinking of the tumour took place gradually, and the collateral circulation became by degrees more fully established, so that, notwithstanding some lividity of the toe-nails and diminution in the temperature of the limb, the recovery was complete. The patient returned to his office a month from the commencement of treatment, and up to the present time the cure of the aneurysm had remained perfect. Unhappily, however, the nervous affection has steadily progressed, so that the sufferer is now unable to walk.—Dr. HADDEN referred to a case of locomotor ataxy associated with perforating ulcer for which amputation of the foot was performed, in which the hæmorrhage proved refractory. The nerves and vessels of the amputated limb showed marked changes.—Mr. THOMAS SMITH debated the question of treatment, and said that he had a predilection for hastening on the cure. It was interesting to observe that in Dr. Longhurst's case the pulse in the posterior tibial artery disappeared altogether one day and then returned the next. In cases of locomotor ataxy he should prefer to tie the artery on account of the general constitutional state; for in the patient under consideration the nervous troubles made rapid progress, which he could not but attribute to the taxation of his nervous forces resulting from the treatment by compression. In one case of perforating ulcer occurring in locomotor ataxy that had come under his notice, the patient died from hæmorrhage after amputation of the limb. He had operated on a case of locomotor ataxy for disease of the tongue: the wound healed very well and there was no trouble from hæmorrhage.—Mr. T. BRYANT considered that the treatment that was adopted was the most reasonable, but thought it should be given up if the capacity of the patient for endurance broke down. It was more likely to be successful than ligature, owing to the presence of arterial disease; in tabes dorsalis the blood was in much the same condition as in health. Doubtless, also, the rapid treatment was the best, and less likely to tax the patient's powers. Noting the fact that there was no murmur, it was probable that a large opening existed between the artery and the aneurysm; in such cases a complete cure required coagulation in the vessel as well as in the aneurysmal sac, and it was easy to understand how all the clot could get washed away.—Dr. CARRINGTON thought it should not go forth from this Society that there was any necessary connexion between arterial disease and locomotor ataxy without some kind of protest. So far as he knew cardiac or arterial changes were not of common occurrence

Digitized by Google

in tabes dorsalis.—Dr. HADDEN said that he thought the connexion was one that had received very general assent of late.—Dr. A. MONEY remarked that several papers had appeared in the *Lyon Médical* by M. Teissier and others pointing out the frequent association of cardiopathy and arterial disease with tabes dorsalis.—Dr. LONGHURST, in reply to Mr. Smith, said the patient had no morphia.

Mr. MEREDITH read notes of a successful case of Laparotomy for the relief of Acute Intestinal Obstruction following upon Ovariotomy. The patient, a feeble old woman, aged fifty-eight, was operated on at the Samaritan Free Hospital in April, 1885, for double ovarian cystoma, complicated by very extensive adhesions (parietal, pelvic, omental, and intestinal). The subsequent progress of the case was in all ways satisfactory during the first week, at the end of which time all sutures were removed after the bowels had acted, the abdominal incision being found well united, and the pulse being recorded as normal. On the evening of the same day the patient suddenly complained of nausea, and soon after vomited a quantity of dark-green fluid. On examination, the abdomen was found free from distension and universally resonant on percussion, excepting immediately over the region of the cæcum, where some dulness was detected. The condition was diagnosed as commencing intestinal obstruction, probably caused by an adhesion band. All nourishment by the mouth was at once stopped, and replaced by nutrient enemata of beef-tea, containing occasional doses of tincture of opium. By the following morning there had been no return of the sickness, but the patient looked worse, the abdomen was somewhat fuller, and the urine passed during the night was for the first time found laden with albumen. Immediate operation was decided upon as likely to afford the patient the only chance of recovery under the conditions believed to exist. On opening the abdomen the peritoneum was found intensely red and congested, evidently in an early stage of acute inflammation. Attention was attracted to a coil of greatly distended small intestine, which was badly kinked and obstructed in consequence of the traction exerted upon it by a portion of the ligated omentum which was closely adherent to its surface. This having been released with some difficulty, owing to the inflamed and softened state of the bowel, another distended coil similarly obstructed by a separate omental band was also set free. No further obstruction being discoverable, the abdomen was then closed. The acute symptoms were at once relieved by the operation, and the temperature fell to normal again on the third day, but convalescence was tedious. No evacuation of the bowels took place until the twenty-third day, when fæcal matter was for the first time detected in the rectum, and relief followed upon the use of an enema. Thenceforth the bowels acted daily, and the patient left the hospital on May 16th, exactly six weeks from the date of her first operation. When last heard of at the end of October, she stated that she had quite recovered her health and was about to resume domestic service. In commenting on the case, Mr. Meredith urged the advisability of early resort to operation under similar circumstances, quoting an instance in his own practice where the patient's life might readily have been saved by such means.—Mr. T. SMITH asked whether the albumen in the urine was associated with the employment of the carbolic spray.—Mr. MEREDITH replied in the negative.

The following living specimens were exhibited:—Dr. Radcliffe Crocker: Arsenical Pigmentation in a case of Chorea. Mr. Malcolm Morris and Dr. F. Semon: Lupus of Face and Larynx. Mr. Clutton: Tubercular Ulceration of Palate. Dr. S. Mackenzie for Dr. Handford (Nottingham): A case of Xeroderma (? Myxœdema).

MEDICAL SOCIETY OF LONDON.

Irritable Brain and Congestion of the Brain in Children.—Simple Pneumothorax, with rapid recovery.

AN ordinary meeting of this Society took place on Monday last, Mr. Brudenell Carter, F.R.C.S., President, in the chair.

Dr. DAY read a paper on Irritable Brain and Congestion of the Brain in Children. He considered that the essential proximate cause of cerebral irritability was anæmia. Many individuals about to suffer from nervous headaches experienced curious sensations of restlessness and depression, probably due to cerebral anæmia. The causes of cerebral irritation were very numerous; sometimes it followed accidents either to the head or some other part of the body; it supervened at other times on chronic illness or acute disease. It was as much a primary disease in some cases as irritability of the larynx or bladder. Sometimes the irritability led to congestion, and this to meningitis. Irritability was, again, a symptom of actual disease of the meninges or brain. Many cases were read illustrating Dr. Day's remarks. He believed that in many cases cold sponging was the best method of reducing the febrile temperature. Cerebral irritation is frequently accompanied by fever and often followed by frontal headache. Excessive heat or profound cold may set up congestion of the brain. Delay in the treatment of such cases may allow of the development of coma, which leads to death. The distribution of the blood may be unequal in different parts of the brain, some being congested, others anæmic. Congestion of the brain very early succeeds irritation; if, indeed, it do not sometimes accompany irritation. A want of balance in the venous and arterial circulation of the brain may disturb its functions. In some cases there are negative symptoms—lassitude, change of manner, without fever, vomiting, or constipation. After lasting for some time, this stage may be succeeded by one in which positive signs and fever develop. In diagnosis the temperature is of but little value unless taken in connexion with other signs. The temperature of the body is very mobile in some nervous children. It is difficult, if not impossible, to draw the line between active congestion and inflammation.—Mr. R. B. CARTER considered that hospitals for sick children afforded a fine field for ophthalmoscopic observation in cases of cerebral disease. He remembered that M. Bouchut had drawn a distinction between neuritis and perineuritis; for the optic nerve received its blood-supply from the anterior cerebral, whilst the coverings of the nerve were supplied from the pia mater. In a case of coma after convulsions he had noticed the same colour as the surrounding fundus in the optic disc. In an undoubted case of meningitis he had seen there was the perineuritis that M. Bouchut had described.—Dr. CHARLES WEST doubted whether the observations of Bouchut were of much scientific value. The ophthalmoscope might corroborate a diagnosis, but it seldom initiated one. Most of the cases that Dr. Day had brought forward were probably examples of congestion rather than mere irritability. Pure and simple meningitis in the child was of very rare occurrence. Tubercular deposits might give rise to various symptoms, and when inflammation supervened the clinical source suddenly altered its character, vomiting being a notable symptom.—Dr. SANSOM spoke chiefly of the peripheral causes of cerebral irritation. In his experience, hypermetropia, and myopia more rarely, were often a cause of cerebral symptoms, simulating irritation. In a case which was first looked on as dyspepsia Dr. Sansom discovered optic neuritis, and gave a grave prognosis. Vomiting supervened later on, and opisthotonos developed. A sarcoma of the cerebellum was discovered. Although neuritis existed, there was sometimes no defect of vision.

Dr. WHIPHAM read notes of a case of Sudden Pneumothorax. The patient was a man aged twenty-one, who caught a severe cold. He was admitted into hospital on Dec. 10th, 1885. The condition began on Dec. 4th with a violent pain at the lower part of the right side. There were amphoric sounds over the right side; the vocal fremitus was fairly distinct, although most of the other signs of pneumothorax were present. On Dec. 14th the patient was so well that he was put on ordinary diet. On Dec. 23rd the air had become so far absorbed that the liver was at its normal level. In the middle of January the man was discharged well. A few other cases had been recorded, altogether eight in number. Five occurred in individuals under the age of thirty-seven. Dr. Thorburn's and Dr. George Johnson's cases occurred in lungs in which there was no obvious previous disease, and it was suggested that adhesions of the pleura had undergone alterations allowing of rupture. In Dr. S. Mackenzie's patient, aged fifty-seven, there was emphysema. Vogel believed that latent tubercular cavities might be the cause of sudden pneumothorax. In cases of the kind under consideration absolute rest seemed to be all that was necessary for perfect recovery. Active interference would be but seldom necessary, only when dyspnœa or cardiac distress seemed to call for it.—Dr. S. WEST had recorded a somewhat similar case in the Clinical Transactions, and had collected twenty-four such cases. The comparative absence of symptoms in Dr. Whipham's case

Digitized by Google

was remarkable, for in healthy individuals the symptoms at the onset were very severe. Most of the patients were under the age of thirty. He thought it was very doubtful whether in the majority of cases there was not a gross lesion. In experimental pneumothorax of animals it was difficult to maintain the affection, as the air was rapidly absorbed.

HARVEIAN SOCIETY.

Compound Fracture of the Patella.—Sprained Joints.

A MEETING of this Society was held on Thursday, March 18th, J. Hughlings Jackson, M.D., F.R.S., President, in the chair.

Mr. G. R. TURNER read a paper on Compound Fracture of the Patella. The patient, a fireman, aged thirty-two, was admitted into the Seamen's Hospital on June 1st, 1885, with a compound transverse fracture of the patella. The cavity of the joint was open through a contused wound, two inches and a half in width, from which blood was exuding, the patellar fragments being separated by about half an inch to an inch. Thorough cleansing under antiseptic precautions, the limb being fixed on a straight posterior splint, with the wound left open, constituted the first treatment. A blood-clot subsequently was found to be projecting between the fragments, but it was not disturbed. At the end of the sixth week a small sequestrum came away from the lower fragment. The man made an excellent recovery, and was discharged in October with power to flex the knee nearly to a right angle, the fragments being then separated by about one inch and a quarter, and by three quarters of an inch when the limb was extended. In his comments upon the case, the author referred to the slight separation of the fragments in cases of compound fracture, possibly due to the escape of fluid from the joint; to the aseptic course of the case, notwithstanding partial necrosis; and to the question of treatment, in which he gave the preference to the expectant plan as opposed to wiring. The paper was concluded by a detailed summary of nineteen cases of this injury at present on record.—Dr. WALFORD described a case of compound fracture of the patella, in which, with partial antiseptic treatment, recovery had taken place in four months.—Mr. PICK commented on the influence of antiseptic treatment in lessening the gravity of the injury, and related the details of a remarkable case under his own care, ending in synostosis of the joint. He believed in very thorough cleansing of the wound, the edges being left open to admit of any putrescible matter being kept antiseptic. The separation of the fragments depended upon the amount of fluid effusion, but it was much more marked in cases where the capsule was torn.—Mr. GANT pointed out that in one case complete success had been obtained without antiseptics, although he had no doubt as to their value. He should never employ wiring in cases of simple fracture, the less severe treatment being quite as successful in its ultimate results, but he would use it in every case of compound fracture where the joint was once opened. Any great effusion, either of serum or blood, should be drawn off. In ordinary fractures he had used gutta-percha pads, drawn together by Malgaigne's hooks, with success. Where all the bones were injured by any form of destruction or partial anchylosis, he should prefer excision of the joint.—Mr. J. H. MORGAN referred to Mr. Pick's case, and observed that in the presence of much effusion union was assisted by the removal of the fluid. In such a case he should prefer to suture the fragments.—Mr. FITZROY BENHAM suggested that the limb should be kept flexed at an angle of 10°, believing that no action of the quadriceps extensor was liable to take place in that position.—Mr. TURNER, in reply, commented on the extreme rarity of compound fracture of the patella. He had found one case of suppuration in simple fracture.

Mr. EDMUND OWEN read a paper on Sprained Joints, in which he urged that a sprained joint should be dealt with on the same principles as those which guide the surgeon in his dealings with a fracture at or near the articulation. He advocated rest and compression for the joint, and maintained that if only the parts be at once enclosed within a plaster-of-Paris casing, with even compression, effusion will be prevented and pain allayed. He employed Croft's method of applying the gypsum splints, and urged its adoption in preference to lotions, ice-bags, simple bandaging, and strapping. He instanced various illustrative cases.—Mr. GANT would recognise two classes of sprains: those in which the tendons were affected, and those in which the ligaments only were injured. He related a case in which the extensor tendons had been torn by the foot being doubled under the leg. Passive movement should be employed early, even though pain was caused thereby.—Mr. KIALLMARK advocated the use of American plaster applied at once, instead of evaporating lotions. He would allow passive movement as soon as it was possible without causing pain.—Mr. PICK thought it difficult to decide when to begin passive motion, but he should generally begin early and persevere, using evaporating lotions at first. He referred to the use of very hot water in recent sprains on the stage.—Mr. VASEY mentioned the successful use of clay mould applied at once round a sprained joint.—Mr. OWEN, in reply, observed that he would be guided by the heat or coldness of the joint, and not by pain, in deciding when to commence passive motion.

EPIDEMIOLOGICAL SOCIETY.

Cholera in Fleets and Ships.

AT the meeting of this Society held on Wednesday, March 10th, Dr. Dickson, President, in the chair, a paper was read by Sir WILLIAM SMART on Cholera in Fleets and Ships. The author pointed out that one of the earliest English observers of cholera was Mr. Curtis, of H.M.S. *Seahorse*, and of the Naval Hospital at Madras, in 1782, who called the disease the "cramps," and the same name was used by Mr. Girdlestone, surgeon of the 101st Regiment, which regiment landed at Madras that year, and was at once attacked by cholera of the most intense type, the cramps being the most prominent symptom. At that time Dr. Paisley, the head of the E.I.C. Medical Staff at Madras, considered the disease to be the same as that which prevailed epidemically in London in 1669-70, which bore the name of "cholera morbus," applied to it by Dr. Sydenham at the time; of which, in contrasting it with ordinary summer cholera, he states: "It differs from that as far as the poles are asunder." To Dr. Paisley the application of the name to the Asiatic disease appears to have been due. After Curtis, who published in 1807, we have no naval authority on cholera, although it must have been seen by surgeons of ships in the East Indies. In 1833 it was among our ships at Lisbon, when the Spaniards denied its presence in Spain; it also was seen in the West Indies. In 1837, when epidemic at Malta, some ships were infected. In 1850 the squadron at Malta was severely attacked throughout the summer, and three times it appeared from infection received in the harbour, but from all the ships the disease disappeared when they were taken to sea. In 1854 it broke out in the fleets in the Black Sea and the Baltic. In the former the infection was brought from France, and it ravaged five ships, especially the *Britannia*, of which Sir William Smart gave the history in detail. He mentioned the length of exposure in some ships, twenty having cholera from the third to the seventeenth day after entering the infected port. The fleet went to sea, and in three of the line-of-battle ships there were violent outbursts at sea. That in the *Britannia* was the worst, and she returned to port on the fifth day, having lost 50 men in the first twenty-four hours of the outburst, and 93 out of 201 attacked in five days. She was cleared out and smoked, after which the disease ceased in her. Eighty-five men were transferred to the *Apollo*, of whom 26 died. The nurses sent with the sick were attacked, and some died, but the crew of the frigate were not at all infected by their visitors being eleven days on board. The Baltic fleet was infected with variola on leaving England, and that was followed by fever; but three months had elapsed when cholera appeared in the Gulf of Finland. With cholera on board, the combined fleet, English and French, went up the Gulf to Cronstadt, where the infection became worse; then it went to the mouth of the Gulf, and it had nearly disappeared when the French army arrived from Brest, bringing among the troops fresh infection to attack the sailors and marines who had landed to besiege Bomarsund, and thence took it to their ships. The French troops and ships suffered much more than the English. On Sept. 17th the French ships left for home, taking their troops, but the English did not leave the Baltic till Dec. 7th. In that fleet there were no severe outbreaks as in the Black Sea fleet, and the disease was more of the diarrhœal type. In the Black Sea there were 655 attacks of cholera

Digitized by Google

with 354 deaths, and in the Baltic there were 327 attacks with 124 deaths. The author went on to give facts and details of the severer visitations of cholera in ships on the East Indian stations at recent periods. In 1858, the year of the second China war and of the Indian Mutiny; and in 1862, when our forces were directed to repel the Taeping rebellion, the *Euryalus*, whose crew had had no leave since quitting England, arrived, and next day part of the crew formed a boat expedition up the river, of which the water was drunk by them, and on the fourth day they landed and scoured the country. That same night cholera broke out in the party, but on returning to their ships no ill effects resulted to those who had not gone on the expedition, and the whole epidemic of cholera became one of dysentery and remittent fever. Sir William Smart said he had no reason to believe that cholera could be communicated by close contact; but there must be an infectious "aura" from the sick or their excreta, where cholera is of an epidemic type, that reproduces the disease in others, of which there was to his mind proof in the secondary infection of the marines in H.M.S. *Queen* in 1850. He had witnessed nothing to give support to the doctrine of Pettinkofer, but believed in the necessity for keeping the decks as dry as possible whenever any kind of bowel disorder was epidemic in crowded vessels. Although admitting that the theory of Koch may explain some phenomena of epidemic cholera, yet he finds no support to that theory in the terrific and sudden outbursts he has had to speak of; but he feels that it is not inconsistent with what appears in those epidemics that grow up more slowly by isolated cases, that may or may not culminate in an outburst of the disease. It appears that in epidemics the ratio of diarrhœal attacks increases proportionately with that of cholera attacks and mortality, thus showing that the diarrhœa was a constituent of the epidemic. In the worst infected ships this was equally observed, also that the first victims to cholera in the outbursts were the men already under treatment for diarrhœa, which adds support to the idea that the great majority of diarrhœal cases occurring in cholera epidemics possess the potentiality of development into the rice-water collapse type of the same disease.—In the discussion which followed, the President, Dr. Lawson, and Dr. Pringle took part.

CAMBRIDGE MEDICAL SOCIETY.

AT the meeting on Friday, Feb. 5th, Mr. WHERRY related a case of Inflammation of Joints Following Injury to Spine, occurring in a labouring man, aged fifty-four, who was working on a stack in the dark of early morning of Dec. 24th, 1885, when he fell off, dropping about eight feet on to his left side. He walked home with pain and difficulty a distance of over a mile, laid in bed drowsy, without appetite, and only just able to slowly move his limbs. After a week in this condition he was carried into the hospital on Dec. 31st. On admission he was drowsy and stupid, and answered questions in a dull manner when roused. Skin sensation seemed perfect everywhere. The movements of the limbs were very slow, difficult, and painful; no rigors, no sweats, and no bladder symptoms; bowels confined. He had always had good health, and was working daily up to the date of the accident. On January 1st, 1886, there was some swelling of the left wrist, fingers, and both ankle-joints, with pain on movement and tenderness, relieved by an opiate. Heart-sounds normal; evening temperature 101·6°. Next day there was marked redness and swelling of the left wrist-joint with œdema, and of the joints of the first and second fingers; beads of sweat on the left forehead, and a few small herpetic vesicles along the course of the left supra-orbital nerve; tears and secretion excessive in conjunctival sacs of left eye; pulse 80; considerable œdema of both ankles; patient drowsy; no general sweating; urine acid. The bowels acted after calomel. Evening temperature 101·4°. On Jan. 3rd the redness and swelling in the left wrist continued, as well as in both ankles; drowsiness and stupor; muco-pus in conjunctival sacs of left eyelid, not in right. The knees were usually kept drawn up in the bed, and were put down with an effort. Morning temperature 100·2°; evening temperature 101·8°. By Dr. Latham's suggestion he was cupped at the root of the neck behind, in two places, and about two ounces of blood drawn. No relief that night. On the 5th there was less pain and tension in the joints. His manner was still stupid and dull. Morning temperature 99·2°. He was cupped again in four spots and four ounces of blood drawn, and five grains of calomel and a grain of opium were ordered.—Jan. 6th: Bowels had been moved three times. Better. Wrist and ankles less swollen. Morning temperature 100°; evening temperature 101°. Mixture of senna and opiate.—7th: Wrists and ankles better; complains of pain in right knee, with some tenderness, but there is no swelling. Blister in four spots along the spine. Opiates at night. Blisters open by savine ointment. Calomel and castor oil in the evening; evening temperature 100·8°.—9th: The right foot and ankle more painful and swollen; the other joints better. Morning temperature 101·2°. Ordered a blister over the lower dorsal vertebræ. Evening temperature 101·8°.—10th: Feels better, and has had a good night; has no longer the dull stupid manner; his mind is clear. Was ordered tincture of opium three times a day. The blister to be kept open with savine ointment. From this time continuous improvement took place. The evening and morning temperature fell daily until the 19th, when the evening temperature reached the normal point, and the blistered surface was allowed to heal. There was some œdema about the affected joints after the redness and pain had passed away, but this entirely disappeared by the 23rd. There was still at this date a little tenderness and thickening about the left wrist. The unilateral sweating of the face was noticed from time to time. On Feb. 2nd the patient was sitting up in bed much improved, and had lost all pain, except now and then in the left wrist. There was some thickening and stiffness about the joints which were affected, and his grip was still weak, though very much stronger than before. Was this a case of injury to the spinal nervous system? There is nothing against this view in the fact that the man walked so far to his home after the injury. It has been especially noted by Le Gros Clark that after severe spinal injuries there might be very little shock, differing in this respect so much from other visceral lesions, There was not any difference between the appearance of the joints and that which manifests itself in rheumatism or rheumatic gout. The small joints and wrists and ankles were most affected, and the left wrist acutely, but the flexion of the knees and hip-joints, which was specially noted, pointed to inflammation, the first sign of an inflammation in a large joint being the constant assumption of a flexed position. There was no history of former rheumatism. With regard to the sweat symptom which pointed to a vaso-motor disturbance or paresis, both general and local sweating have been noticed after nervous shock, as after railway collisions, and one leg has been observed to sweat and not the other. Page tells the story of an alarmed woman who thought her child was about to be knocked down at a railway station, and who was herself knocked down on the platform. Polyuria followed during some weeks, except for twenty-four hours, during which it was replaced by an enormous flow of milk from the breasts; the vaso-motor disturbance seemed to move from one part to another. This patient had a sweating of the left temple, but no general sweating, though the skin was fairly moist. This phenomenon was observed by Mr. Wherry on two occasions, and it was carefully confirmed by others, sources of error such as draughts of air being excluded by screens. Mr. Wherry had been careful to give his own observations as to the facts without hazarding any definite pathology. Dr. Latham, who treated the patient so successfully, had localised the lesion with precision in the medulla oblongata, and considered that the dominant vaso-motor centre therein was disturbed. In the last edition of Erichsen's Surgery, in the account of spinal concussion, the diagnosis from rheumatism is made clear by the statement that "in spinal concussion there is never any concomitant articular inflammation."

Dr. LATHAM showed Uric Acid Crystals which he had prepared by heating together glycosine and urea; a full account of the method was published in THE LANCET of Feb. 6th.

THE PARKES MUSEUM.—The committee of this institution have arranged a course of twelve lectures, commencing on the 3rd inst., for the special instruction of those desirous of obtaining knowledge of the duties of sanitary inspectors. The subjects treated will comprise ventilation, water-supply, drainage, disposal of refuse, food, infectious diseases, nuisances, &c., and the lectures are to be delivered by well-known authorities. The fee for the course is five shillings.

Reviews and Notices of Books.

Handbook of Diseases of the Nervous System. By JAMES ROSS, M.D. London: J. and A. Churchill. 1885.

DR. ROSS's treatise on Diseases of the Nervous System has achieved a high success, and we said of the second edition that it had no equal in the English language. The author therefore comes before the medical public in the capacity of a writer of a Handbook of Diseases of the Nervous System with the prestige that attends a former success in an arduous undertaking. After a careful perusal of the volume before us we have not the slightest hesitation in asserting that it is a very valuable work.

In producing a book of this kind the difficulty is to apportion its dimensions and to assign the amount of detail which shall be entered upon. Its contents should be something between those of a treatise and those which may be found in works on the subject of medicine. That has no doubt been Dr. Ross's aim. Naturally some difference of opinion may be entertained as to which side a handbook should lean, and we confess that we do not feel prepared to say whether more matter should not have been introduced into Dr. Ross's new book. The account of diseases of the nervous system in Dr. Roberts' and Dr. Bristowe's works is no doubt adequate for the general purposes of a physician. It seems reasonable, therefore, to compare those accounts with Dr. Ross's book in order to see in what respect the possessor of his manual would be better off than he who had but a general treatise on medicine to guide him. The number of illustrations in the handbook is unquestionably one advantage. Not that the illustrations possess much originality, for most of them have done duty in other works; but we have here brought together a very valuable series, which cannot fail to increase the reader's interest and elucidate the text. Additional advantages in the handbook are to be found in more accurate and detailed descriptions of the pathology and clinical symptoms of nervous disease, as well as fuller guidance in the methods of treatment. As to Dr. Ross's style, it is clear and terse; the matter has been well digested; the facts have been gathered from many sources, including the author's own experience; so that, all things considered, it is evident that we have before us a very valuable contribution to the knowledge of diseases of the nervous system. Dr. Ross's *forte* is his wide reading and powers of assimilation, combined with the necessary literary powers of expression in the conveyance of the information that he has to impart.

The mode of arrangement of the work is excellent. The first chapter is an "anatomical introduction," treating of the formation of nervous constituents, of nervous tissues, and of a nervous system on the lines of the theory of evolution. The physiological introduction corresponding to this is treated in the second chapter. Then naturally follows a chapter on General Morbid Anatomy and Physiology of the Nervous System, in which disease is regarded as a dissolution of the nervous system, using the term in the sense given it by Hughlings Jackson, as the process the very opposite of evolution. General Symptomatology is dealt with under the headings of æsthesio-neuroses, tropho-neuroses, and kinesio-neuroses—or disturbed sensory, nutritive, and motor functions. A chapter on General Treatment concludes the first part of the work on General Pathology. In this first part Dr. Ross displays the same kind of originality that is met with in his treatise—we refer to the adoption of the method implied in the principle of evolution as expounded by Hughlings Jackson. The Special Pathology treats of the various diseases in the following order: General diseases of the peripheral nerves, disorders of common sensation and of special sense, spasmodic disorders, atrophic paralyses, spasmodic paralyses, disorders of motor coördination, vascular diseases of the spinal cord, myelitis, spinal meningeal diseases, functional disorders, shock, concussion and allied conditions, vascular diseases of the brain, encephalitis, atrophy, hypertrophy and tumours of the brain, aphasia, diseases of cerebral membranes, paralysis agitans, multiple sclerosis, and chorea. The final chapter is one on General Diagnosis.

The reader will look in vain for heterodox or unauthorised statements; he will have to unlearn nothing. The printer's part of the work has been, on the whole, well done. Many typographical errors have been allowed to remain in the text, but most, though not all, of them have been corrected in a list of errata—the length of which is doubtless due to the work having been printed in America, the author possibly not having read the revised proof-sheets.

All But: a Chronicle of Laxenford Life. By PEN OLIVER. London: Kegan Paul, Trench, and Co.

UNDER the above title the author of "Charley Kingston's Aunt," &c., has again occupied his August and September vacation time in writing a pleasant romance depicting country life. It is now pretty generally known that it is Sir Henry Thompson who, under the *nom de plume* of Pen Oliver, has thus occupied his holiday in making a sketch after nature, which he has dedicated to one of his oldest friends, Dr. Russell Reynolds, first met among a crowd of freshmen at the gate of University College. It is pleasant to find two men, equally distinguished in their respective spheres, whose acquaintance, first commenced as students, has now ripened into friendship so highly prized. When others in the profession read, as we doubt not they will, this second volume of fiction by Pen Oliver, they will feel, as we have done, that the author has a wide sympathy for other and less distinguished members of the profession which he has himself adorned and elevated by his own career; for one of the characters in his work is a country doctor, Archibald Hamilton, "the chief—it might be said the only—medical man in Laxenford," a supposed country town in Suffolk. Sir Henry Thompson's description of Archibald Hamilton would apply to many a provincial practitioner:—

"He is indeed a good specimen of the metropolitan medical teaching of his epoch..... As not unfrequently happens to many a good student, a curriculum which consumes not less than seven years, counting from the date of leaving school, during which earnings are rarely possible, may consume also a large share of his patrimony, and necessitate an entry on remunerative occupation without long delay. Men of parts, who if they had capital to support the cost of living in London for a few years might pursue laborious scientific inquiry and rise to high distinction, are often compelled to devote themselves to the routine of professional life in the provinces, where, under conditions very favourable to health, a moderate livelihood, amid fair country society, may be speedily acquired. Nevertheless, much assiduous work must be accepted with small remuneration for several years before a position of comfort can be attained. Thus it is, happily for the inhabitants of many an outlying country district, that the local doctor is a man of considerable knowledge, with broad views, a good observer, and prompt to act judiciously in emergency. There are many men thus situated who are the equals in ability to some of the best in the metropolitan area, although in the country they have of course missed opportunities for improvement which city life would have afforded them, had they been able to remain within its influence."

We hope, too, most country doctors are as fortunate as the practitioner at Laxenford in their "other self and better half," who awaited her husband at home with a pleasant welcome after the toils of the day, and parted with him on a second summons to duty, "while a kiss or two played hide-and-seek in the silky mazes of the luxuriant brown beard"—to "work, moreover, much of which is never paid for and

Digitized by Google

never expected to be, but by the gratitude of the indebted." But it is not to a description of the routine life of a country doctor that the work is devoted, but rather to the influence for good which a sound scientific training and high moral tone can exercise in a country district among all classes of society. The country labourer whose "missus is took bad" finds in him both doctor and friend, and my lord and lady of "Laxenford Hall" value his friendship not less than their poorer neighbours. "Signs of family trouble at the Hall set in"; and it is in smoothing these and averting a terrible catastrophe that Dr. Hamilton plays a principal part. We will not enter more into detail, but recommend our readers to peruse this pleasant production of Sir Henry Thompson's leisure. It is admirably illustrated by woodcuts, sketched by the author himself, of which "the doctor's house at the corner of High-street" is one of the prettiest.

OUR LIBRARY TABLE.

Catalogue of the Pathological Museum of the Western Infirmary, Glasgow. Compiled by JOSEPH COATS, M.D. Glasgow: A. Macdougall. 1885.—A good catalogue is an indispensable requisite for every museum, and it is gratifying to find that this fact has of late years received so much recognition at the hands of curators of the various valuable pathological collections in the metropolis and elsewhere. The latest addition to such volumes has been compiled with a care and accuracy which deserve imitation; and Dr. Coats has, whenever possible, supplemented the descriptions of the specimens with an outline of the clinical history of the cases from which they are derived. The Museum of the Western Infirmary of Glasgow appears to be one of great excellence, containing many specimens of rarity as well as abundant examples of the more common types of disease. Amongst the former may be cited: A specimen of fracture of the patella with ligamentous union after wiring, death occurring from fracture of the skull seven months after operative measures; one of a remarkable cyst of the head of the fibula; one of hernia of the pericardium; two of obstruction of the thoracic duct with chylous ascites; one of double uterus; two of tuberculosis of the Fallopian tubes and uterus; one of round-celled sarcoma of the thyroid penetrating the trachea. The series of specimens of diseases of the organs of circulation, especially of cardiac valvular disease and of aortic aneurysm, and that of lung disease, are particularly rich; whilst the specimens of uterine and ovarian tumours and of urinary calculi are numerous and varied.

Transactions of the Medical and Chirurgical Faculty of the State of Maryland, 1885.—The chief contents of this volume are: The Study of the Physiological Action of Drugs, by Dr. Newell Martin; Rectal Medication, by Dr. Cattrell; Report on Six Cases of Penetrating Gunshot Wounds of the Abdomen, by Dr. Randolph Winslow; Observations on the Origin and Cure of Hay Asthma, by Dr. J. N. Mackenzie; Carbon as an Antiseptic Dressing for Wounds, by Dr. David Stewart; Hard Chancre of the Tonsil, by Dr. Frank Donaldson; the Report on Surgery, by Dr. R. W. Johnson; that on Antipyrine, by Dr. J. S. Lynch; the Report on Obstetrics, by Dr. J. Morris, and on Gynæcology, by Dr. S. E. Neale; Report on Materia Medica, by Dr. E. F. Cordell; the Tonic Effects of Travel, by Dr. Van Bibber; Disposal of the Dead, by Dr. Rohé; Cocaine in Ophthalmic Surgery, by Dr. H. Harlan.

The Light of Life, or the Secrets of Vegetable and Animal Development Detected and Explained in Strict Conformity with Known Natural and Chemical Laws. Edited by JOSEPH JOHN KAIN. London: Wyman and Sons.—An inquirer after knowledge taking up this work, the title of which is calculated to raise the expectations to a considerable height, will, after getting somewhat mystified with the first chapter, on glancing at the second, entitled "Man Formed from a Centre—Man a Fruit of the Earth and Air," be interested to learn that "the centre" is the umbilical cord, and that man's first form is moulded and apportioned to the "three sides of the triangular figure of the womb." If this information is insufficient and the remaining pages be turned over, the reader will learn that germs do not cause disease; that vaccination is useless; that atmospheric pressure is the cause of the circulation, and friction of the corpuscles against the walls of the vessels produces animal heat.

The Pytchley Book of Refined Cookery and Bills of Fare. By Major L——. Pp. 280. London: Chapman and Hall. 1885.—This book appears to us to supply a want by furnishing a number of bills of fare for nice small dinners within the compass of men of ordinary means. The quantities required for the different dishes are given with a due regard to the prevention of needless waste, and in plain language. The bills of fare, which appear to have been drawn up with good judgment, are given in French and English—at least that was the author's intention; but many of the French names of the dishes are clearly wrong, and we are hardly prepared to acknowledge "beignet au parmesan" and "marrow aux fine herbs" as English. If the book reaches a second edition, and we think it deserves to do so, it is to be hoped that the author will have the names revised. At the end of the book there is a most excellent chapter on wines and their service.

Dictionary of National Biography. Edited by LESLIE STEPHEN. London: Smith, Elder, and Co.—We have received the sixth volume of this work. It includes biographies from Bottomley to Browell; and in every respect is equal to the preceding volumes, of which we have at the time of their receipt spoken in highly laudatory terms. When completed, the work will be an invaluable addition to a library.

The Therapeutic Gazette.—This is a monthly journal of physiological and clinical therapeutics. It contains a vast amount of information, specially valuable for men in actual practice. It has met with great success in America, and we venture to think its reasonable price (two dollars a year) and its practical character will commend it to the general practitioner and others in England.

New Inventions.

GLASS PIPES IN SANITATION.

FOR years past this idea has been mooted, though never yet successfully carried out in practice; but we are pleased to observe that it is now perfected by the Cooper's Patent Glass-lined Tube Company at their works, 3, Dyer's-building's, Holborn. The samples submitted to us prove that glass pipes from ½ in. diameter upwards, and lengths from 1¼ in. to 6 ft., inserted into wrought iron pipes of any bend or angle required, and secured therein by rigid cement so as to be practically homogeneous, will withstand any alternation of heat and cold, from 212° F. to 32° and lower, cannot, when fixed, be broken by any accidental mechanical violence, are hermetically sealed in their entirety, and so seem specially adapted to the requirements of breweries, laboratories, chemical manufactories, large milk establishments, and numerous other applications in the arts. While for all hygienic purposes they are immeasurably superior to the tin-lined lead pipes, which until now have been recommended, for the conveyance of water, and especially good soft water, in its pristine state of purity, from its source to its delivery.

THE AURAL RESERVOIR.

THERE are certain inconveniences connected with the syringing of an ear. The surgeon wants both his hands free—one to work the syringe, the other to draw the auricle upwards, backwards, and outwards. Therefore an assistant is required to hold the receiving vessel. Then the patient's neck is encircled by a towel, which fulfils its purpose indifferently, and the patient goes home with a clammy neck and a demoralised collar. Messrs. Arnold and Sons have made at my suggestion an appliance which I find greatly facilitates the procedure. The aural reservoir consists of a cup, the back of which is flat and prolonged upwards, forming an ear-piece, through an opening in which the ear to be syringed is passed. It is provided with a stout wire handle, by which *the patient* holds it *in situ*. It is best held by the hand opposite to the side on which the ear is being syringed, and not by the hand of the same side, as represented in the accompanying figure. The advantages of the aural reservoir are—

1. It enables one to syringe an ear without the aid of an assistant. 2. It effectually prevents the least drop of water from trickling over the patient's neck. 3. It is simple, unbreakable, and cannot get out of order. It is made of tin, bronzed and enamelled, and comes up to the usual artistic finish of Messrs. Arnold's work.

M. J. MOLONY, L.R.C.P., L.R.C.S.,
Surgeon, Arklow Quarries, &c.

LACRYMAL SYRINGE AND COCAINE HYPODERMIC INJECTOR.

THESE instruments have been made for me by Messrs. Pickard and Curry for applying solutions to the lacrymal sac, and are represented in the accompanying illustration, lying in portable case. The syringe was originally designed to enable patients themselves to inject medicated fluids directly into the tear-bag, and I have found it of great assistance in thus treating severe cases of dacryo-cystitis which had previously remained unrelieved. Both syringe and injector are also specially serviceable for the application

of cocaine in ophthalmic operations, as iridectomy, tenotomy, enucleation, &c.; for when charged they can lie on a tray ready for use with other instruments. The rubber can be easily removed, the several portions cleaned and rendered aseptic, whilst the contents of the glass bulb can be seen and estimated. The advantages of cocaine as a local anæsthetic are so great and so often demanded in all departments of surgery that the convenience and economy secured by the use of these little instruments will be at once understood and appreciated.

Tunbridge Wells. G. ABBOTT.

THE REPORT ON THE DOGS' HOME.

THE report of the Committee of the Dogs' Home, read at the public meeting on Wednesday, is quite a national document in relation to the "friend and companion of man." In the year 1885 the Home received no fewer than 25,578 of these animals, of which 25,228 had previously been run in by the police and then brought to Battersea. Of the whole number 2236 had new homes found for them, and 2379 were restored to their owners. The remainder, amounting to 20,963 unclaimed, received their euthanasia in the lethal chamber, of which the committee reports "that it has admirably fulfilled all the predictions made in its favour by performing its work with admirable precision, never showing the least failure as a humane agent, but invariably and with perfect efficiency putting to death by a painless sleep each and every animal placed within its walls." To have saved all pain of death to over twenty thousand dogs in one year is something in the history of civilisation that may on a future day rank as a fact worthy of more than the passing note that must now be given to it; but it is right to indicate that as many as 146 persons residing out of London sent animals to the chamber, some from long distances, two from Scotland.

In connexion with the necessary killing of dogs at the Home the report mentions an act of grace on the part of the Queen. By the statute the animals need only be kept living three days, a period in the opinion of Her Majesty too short. The Committee has, consequently, extended the period to five days before sending the animals to the lethal chamber, except in the case of animals that are diseased.

The report is specially interesting on another topic—that of rabies. In the year 1885, 60 dogs suffering from rabies were killed at the Home, or just four times the number of 1884. These rabid animals were found in the various months of the year as follows:—In January, 2; February, 4; March, 4; April, 2; May, 5; June, 6; July, 7; August, 5; September, 2; October, 4; November, 9; December, 10. Mongrels, 15; half retrievers, 2; half collies, 2; half Skye, 1; half pug, 1; half pointer, 1; half setter, 1; half Dalmatian, 1; retrievers, 13; collies, 4; spaniels, 4; fox-terriers, 3; greyhounds, 2; lurcher, 1; poodle, white, 1; St. Bernard, 1; Pomeranian, 1; Dachshund, 1; black and tan, 1; Scotch terrier, 1; bull terrier, 1; Bedlington, 1. Of these, 54 were males and 6 were females. These cases were carefully noted in the first instance by the officers of the Home, and afterwards certified by the honorary veterinary surgeon.

The Committee expresses an opinion that it is desirable, in order that the statistics of rabies may be made trustworthy and complete, that the bodies of dogs alleged to be rabid, whether killed by the police or other persons, should be examined by a veterinarian, who should report to a Government department the result of his post-mortem investigations; also, when a dog exhibits signs of rabies at a police station, instead of a police constable being told off to kill it, a veterinarian should be called in, and in the event of his certifying that the dog is rabid, then the animal should be destroyed by him in a merciful manner. Such measures would, it is believed, materially allay panic in the public mind during the prevalence of rabies by checking and correcting erroneous and exaggerated impressions generally circulated at such times; for it is notorious that the most appalling ignorance exists generally throughout the country as regards the nature and symptoms of rabies. The Committee hope that some such arrangement may be made by the Government, and are glad to state that recently it was ordered by Sir Edmund Henderson, late Commissioner of Police, that a test of this kind should be made as regards a given number of dogs destroyed by the police in the streets of London, whose bodies will be submitted to Mr. A. J. Sewell, the veterinary surgeon to the Home, for post-mortem examination. We need not say that we concur heartily with these sensible propositions, and indeed we feel that the whole report is of a tone which commends itself to the scientific as well as to the philanthropic world.

On the 25th ult. Major Tulloch, one of the inspectors of the Local Government Board, held an inquiry relative to an application by the Cheshunt Local Board of Health for permission to borrow £38,800 for carrying out works of sewerage and sewage disposal.

THE LANCET.

LONDON: SATURDAY, APRIL 3, 1886.

"THE President of the Royal College of Physicians of London shall be elected annually, on the day after Palm Sunday, as required by the Statute 23 & 24 Vict. c. 66, s. 6." So runs the wording of the thirty-ninth bye-law of the College of Physicians, and accordingly a fortnight hence the Fellows will be required to perform a duty which in the present year may be fraught with great consequences both for the College and the profession. The present distinguished occupant of the presidential chair was elected to that office in 1881, and during the past thirty years the President has usually been re-elected annually until he has completed a term of five years. Thus Dr. THOMAS MAYO was first chosen in 1857; he was succeeded in 1862 by Sir THOMAS WATSON; to whom followed in order, in 1867, Sir JAMES ALDERSON; in 1871, Sir G. BURROWS; in 1876, Sir RISDON BENNETT; the only exception to the five years' term being in the case of Sir JAMES ALDERSON. We fully admit that, as a general rule, it may be wise for the Fellows not to permit their President a longer term; so much is required of him that it is hardly just to him to request his longer occupancy of the chair; and the longer it is held by one individual the less are the chances of the office being transferred to any of his contemporaries. Still there are occasions when the interests of the College and the still wider interests of the profession may demand the prolongation of a tenure of office, the transfer of which to other hands might conceivably disturb the continuity of a policy which the outgoing President had initiated. In the same manner the College might on occasion exercise its undoubted right, and considerably curtail the customary period of office in the case of a President who had shown himself out of harmony with the wishes of the College. There are precedents in plenty for the prolonged tenure of office, and although they date back to times when the College had but slight relations with the outer circle of the profession, and when consequently its affairs were less interesting and more stagnant, still to those who adhere to precedent the fact may be reassuring. Thus Dr. JOHN LATHAM was President for seven years, being only fifty-two years of age on his first election (1813); his successor, Sir HENRY HALFORD, held office for twenty-four years (1820-44), and Dr. PARIS, who followed, for thirteen years (1844-57), both Sir HENRY and Dr. PARIS filling the office to the time of their death.

It may be asked whether there is any reason why the customary limitation of the years of presidency should on the present occasion be set aside? The Fellows, whose duty it is to elect their President, know well that the College of Physicians has of late years advanced considerably beyond its former restricted limits, and has taken a much larger share in the education of the body of the profession than before. We have often pointed the moral of its conjunction "for examination purposes" with the College of Surgeons. The credit of this salutary change, so far as the College of Physicians is concerned, must be ascribed to Sir W. JENNER and Sir H. PITMAN. The scheme is yet young; it must probably be still further modified in detail; and it seems a pity that its prosecution should be handed over to others, unless, indeed, the presidency could be held by Sir H. PITMAN, whose services as Registrar would then be lost to the College. Again, a few months ago the College determined by a large majority that facilities should be found for enabling those candidates who had qualified at the hands of the Conjoint Board to obtain medical degrees. Is this question to be allowed to lapse because it may chance that an incoming President may be out of sympathy with a movement which is almost unanimously supported by the teaching body in London? Once more, the College in its educational function ought to be so directed as to lead opinion in the framing of the curriculum, and it should therefore possess as its head one who is thoroughly alive to the needs of modern medical education and the capacities of the student. We trust the time is not far distant when the teaching institutions will be to a certain extent controlled and directed by the College, that there may be some guarantee of efficient teaching. The government of the College ought then to be placed in the hands of men who are conversant with all these matters, and who can deal with them as they should be dealt with.

We are conscious that it might be said we are laying too much stress upon the educational aspect of the functions of the College; but this is only because the place the College takes in medical education has grown in importance. If the Fellows as a body recognise this, and desire that the work initiated by the present President should be carried on, let them return him again with so united a voice that he must bow to their decision. Should Sir WILLIAM JENNER consent thus to continue to give his services to the College, not only would the prosecution of educational reform be assured, but the Fellows would be relieved of the very serious difficulty of selecting a new President from amongst those who, having already filled high office in the College, are entitled thereby, as well as by their reputation, to attain the highest office, but respecting whose views upon the pressing questions of the day all is uncertainty. Several names are being mentioned, but with one or two exceptions the physicians thus indicated have not clearly and boldly taken a stand upon the policy which was foreshadowed in the division of January last, or would give that stimulus to its prosecution which would ensure its success. Therefore we think that the approaching election is of great moment. Upon its issue depend the future position of the College and the prosperity of medical education in the metropolis. The new President might be a man of established fame, one who in less critical times could worthily stand as the leading representative of British medicine; but unless he is prepared to guide the College onwards in the path upon which it has entered, it were far better that he were not chosen, and that one who has perhaps less exalted claims should be preferred. It is a critical time, and we shall anxiously await the result of the voting on the 19th. It is perhaps unfortunate that the mode in which the election is conducted precludes any opportunity for the Fellows to become acquainted with the precise views held by the possible recipients of the honour before the vote is taken. It is

Digitized by Google

incumbent, nevertheless, upon every Fellow to support a physician who, being otherwise eligible, has sound knowledge upon the actual state of medical education, and who has shown himself in sympathy with the most urgent question of the day in respect to the qualification of medical men. We trust, however, that the Fellows will not at present determine to which new candidate their support shall be given, as we have strong reason to believe that, under the very special circumstances existing at present, Sir WILLIAM JENNER might be induced to accept the presidency for another year.

THERE is, we fear, too much reason to apprehend that by the time the Lunacy Bill introduced by Lord Chancellor HERSCHELL reaches the House of Commons, if that stage of progress should be reached, it will be little better than a technical amendment of the law relating to the custody of lunatics, and not worth carrying further. While protesting his dislike of the private asylum system, his Lordship is yielding at all points to the pressure brought to bear on behalf of the asylum proprietors, and the prospect that this objectionable system will be speedily or even remotely superseded is daily becoming less hopeful. It is easy to understand that the position of the Lord Chancellor is a trying one, but we had thought that he was made of sterner stuff than previous occupants of the Woolsack, and might be trusted to hold his own, even though the pressure were even greater than it has proved. If Lord HERSCHELL had taken courage to adopt our proposals in their entirety, and left the House of Commons to buy up the existing licensed houses by the creation of guaranteed stock, redeemable by terminable annuities, no wrong would have been done to vested interests, and a decent end might have been once for all made of a great and grave cause of scandal and difficulty, without any direct appeal to the Chancellor of the Exchequer or to the ratepayers. The notion that heavy expenditure would have been necessary in the counties and boroughs to provide accommodation for private patients in connexion with public asylums or the purchase of private houses is groundless, and we cannot but feel that the Lord Chancellor has been ill-advised in attaching any importance to the apprehension. The concession that licences may be renewed or even transferred to successors, or in certain cases to new houses, stultifies the whole measure so far as the extinction of the system is concerned. It cannot possibly die out—at least within any reasonable time—under the relaxed conditions these "amended" provisions create. The Lord Chancellor may have formally placed the rope round the neck of the system, but he has undertaken to leave it quite loose; and he has, moreover, politely removed the drop, so that there is really no reason whatsoever why the condemned should not enjoy a long and happy life, even doing a thriving trade with the aspirants to successful commercial enterprise in the "specialty" of keeping lodging-houses for the insane.

Nor can we regard with satisfaction the encouragement given to the practice of detaining single patients in private houses without adequate supervision. It is manifestly impossible that single patients can be visited at sufficiently short intervals by the present staff of visitors; and we must confess that, looking to the whole of the case, we are by no means disposed to recommend any increase in the number of those essentially useless public functionaries called Commissioners in Lunacy. If the number of these officials were trebled, or even quadrupled, it would not be practicable for them to exercise anything approaching to a real supervision of the insane in private families. There is a too great tendency, even on the part of reformers, to look at this matter from a private and personal point of view, and then to press the notion formed—which is actually, though unconsciously, a selfish one—on the consideration of statesmen, as though it were worthy of being embodied in an Act of Parliament. Stripping the veil off the defence, or even desired extension, of the system of single patients, what do we find? Simply this: that it is a very convenient arrangement for a young or impecunious practitioner of medicine to receive a single patient under his care at a high rate of payment, for which he is supposed to render special services! As a matter of fact, we believe the large class of single cases under the care of medical men are neither well cared for nor advantageously placed as regards treatment. The Legislature, if it is to carry out a genuine and serviceable reform, must shake itself loose from the trammels of that influence which is just now being most sedulously brought to bear upon it by the representatives of the "specialty" in high places, and try to take a common-sense and thoroughly practical view of the needs of the public question. The medical profession as a whole—and it is for this we speak—will be well satisfied with a measure which is framed to place the care and cure of the insane on a simply and purely rational footing; and it will be finally satisfied with nothing less than this. We are of opinion that medical men should be practitioners of medicine, and nothing else. In respect to the scientific practice of medicine in all, or any, of its branches, they are in the position of labourers worthy of their hire; but neither as keepers of hotels or lodging-houses for the insane, nor as boarders of weak-minded folk in private families, ought the members of a profession which, above all others, needs to keep itself above suspicion of mercenary motives, to gain by the care of lunatics. This is the principle we have laid down, to which we have uniformly adhered, and which we are resolved to maintain.

A FURTHER step has recently been taken towards the development of the medical school at Oxford. Influenced by the success of the Cambridge School, the authorities have at last found it necessary to pass some new regulations which will materially lessen the time required for the attainment of the M.D. degree. The student can now present himself for the M.B. examination at any time after he has taken his Bachelor of Arts degree, instead of having to wait for four years as formerly; and, similarly, instead of waiting for his M.D. degree for three years after he has taken his M.B., he need now only have entered on his thirty-ninth term after matriculation, and have had his name on the books of one of the Colleges or Halls, or on the register of non-collegiate students, for twenty-six terms, to be eligible for admission to the higher degree. In fact, the University standing for the M.D. degree is now the same as for the M.A. Degrees in Surgery are instituted for the first time, and every candidate who is admitted to the degree of M.B. will *ipso facto* be admitted also to that of B.S.,

Digitized by Google

whilst he may obtain the Mastership in Surgery in the twenty-seventh term from his matriculation. The regulations for the examination and the composition of the Board of Examiners have also undergone extensive alterations. If the subjects taken by the candidate for the B.A. degree have not included scientific subjects, such as Physics, Chemistry, or Animal Morphology, a preliminary examination in Science must be passed. The special subjects of the first examination for the M.B. degree are Organic Chemistry in its special relation to Physiology and Medicine, Human Anatomy, and Human Physiology. Special exemption is permitted in Organic Chemistry and in Human Physiology if the candidate has already been placed in the first or second class by the examiners in the School of Natural Science in Chemistry or Animal Physiology respectively. Organic Chemistry may be taken by itself, and Materia Medica and Pharmacy may likewise be separated from the subjects of the Second Examination. These subjects are: Medicine, Surgery, Midwifery, Pathology, Forensic Medicine and Public Health, and Materia Medica and Pharmacy. The passing of these two examinations will give the degrees of M.B. and B.S. The M.D. degree will be conferred after the reading of a thesis on a subject connected with the Science and Practice of Medicine, and must include the history and literature of the subject treated of. For the Mastership in Surgery a special examination will be held in Surgery, Surgical Anatomy, and Surgical Operations. For the conduct of the First Examination five examiners will be appointed—viz., one in Organic Chemistry, two in Anatomy, and two in Physiology; whilst for the Second Examination eight will be required—viz., two for each of the subjects of Medicine, Surgery, and Midwifery, and one for Pathology and Materia Medica respectively; Forensic Medicine and Public Health being conducted by the examiners in Medicine, Surgery, and Midwifery. The Regius Professor or his deputy is to act on both boards as senior examiner, and the examiners will be elected for three years. By these statutes the University has brought itself again into touch with modern systems of teaching and examinations, and the liberal and wise spirit in which they have been drawn up speaks well for the future of the Oxford School. It is another victory for science over classics in modern education; for every student who intends to take a medical degree will have a distinct advantage if he takes his B.A. in Natural Science rather than in Classics.

WE are not disposed to criticise or even to analyse Medical Bills not before Parliament. For purposes of criticism a Bill is non-existent till it is introduced. This is a useful and obvious rule, on the score alike of convenience and courtesy, in ordinary times. In such a crisis as the present it is of more than ordinary usefulness. In view of the introduction of the Medical Bill, we may do better service to the cause of true medical reform if we recall roughly the history of the question, and the points in which there has been the greatest unanimity of opinion. The two chief facts in the history of the question are that the subject has been investigated by a Select Committee of the House of Commons, and by a Royal Commission of the first quality as regards authority. The work of the Select Committee was cut short by a change of Parliament and of Government. The evidence taken was of much interest. But the committee was dissolved, with the Parliament, before it had time to make any recommendations. And to the last Government of Mr. GLADSTONE the subject appeared of such consequence as to justify a Royal Commission consisting of the following gentlemen:—The Earl of CAMPERDOWN, the Bishop of PETERBOROUGH, W. H. FORD COGAN, Sir GEORGE JESSEL, GEORGE SCLATER BOOTH, Sir WILLIAM JENNER, JOHN SIMON, THOMAS HENRY HUXLEY, ROBERT MCDONNELL, WILLIAM TURNER, and JAMES BRYCE. If such gentlemen as these did not "scamp" their work the Bill to be introduced by Her Majesty's Government should take their opinions into account. Did they "scamp" their work? Let us hear their own account of their stewardship:—

"We, in obedience to your Majesty's commands, have inquired into all the subjects committed to us for consideration. We have held forty meetings. We have called before us such persons as we have judged necessary, &c. ..... We have examined books, documents, papers, and records. ..... We have also had before us the evidence of the Select Committee."

Clearly, then, this Royal Commission did not "scamp" its work, but went somewhat thoroughly into it. We may now ask what were the leading suggestions of that painstaking Commission? They were two—viz., a reduction in the number of licensing authorities, and a reduction in the size of the General Medical Council. On the first question we must give from the Report of the Royal Commission an extract, which will not only show its opinion, but that of the gentlemen examined. The figures attached to their names in the foot-note give the reference to their evidence:—

"It will be found that for many years a Common Board for licensing has been very generally advocated, even by those whose opinions on other points of medical reform differ most. A proposal to form such a Board for England has been agreed to by all the English medical authorities, and on two occasions approved by the General Medical Council; and a similar proposal for Ireland was also agreed to by nearly all the medical authorities of that country. The principle of a Common Board was introduced into Lord Ripon's Bill of 1870, and has found a place in all the later Government Bills. It has also been advocated by a large majority of the witnesses who have appeared before us.[1] It is our opinion that the holding of a licence ought to be conclusive evidence of sufficient proficiency in medicine, surgery, and midwifery. After a long and careful inquiry, we have arrived at the conclusion *that such a standard of proficiency can only be ensured by reducing the number of licensing authorities.*"

The next great reform recommended by the Royal Commission was a reduction in the numbers of the Medical Council, while at the same time providing for the direct representation of registered practitioners. The reduction was procured by a method which we have always advocated—that of abolishing the representation of individual bodies, and giving a certain number of members to the medical authorities in each division of the kingdom acting

in a group. Clearly this is the right course to take. To leave the existing individual representation of bodies almost intact would be to neutralise and overpower any three or four direct representatives of the profession, as well as to make the Council more unwieldy and at the same time costly. We are aware that the Commission was not unanimous on these points. But the two points were supported by Lord CAMPERDOWN, Mr. COGAN, Sir GEORGE JESSEL, Sir WILLIAM JENNER, and Dr. MCDONNELL, and they are advocated by the great bulk of the profession. We cannot forget them or say that a Bill which does not secure them will meet the demands of the case, or the just and wise expectations of the profession.

AT a public meeting which was held last week at the Mansion House, Cardinal MANNING made reference to the evidence which was given before the Royal Commission on the Housing of the Working Classes, and to the conclusion of the Commissioners, that while ample machinery and legislative powers exist for the remedy of insanitary conditions in the metropolis, the great want is some body which would put the machinery in motion. This want, he pointed out, is now supplied by the Mansion House Council on the Dwellings of the People and its local committees, which take cognisance of all failures of sanitary administration throughout the metropolis, and, by making representations to the vestries and district boards, lead to their remedy. The effect of the work of the Council during the last year was that over six thousand well-founded complaints received the attention of the proper authorities. The Council have therefore conferred no small boon upon the metropolis, and have shown the various local authorities that an organisation exists which is ever watchful over the interests of those who have reason to complain that their representations have been unheeded.

This is, however, but the smaller portion of the good the Council have done during the year; the larger is the outcome of the communications they have addressed to the Secretary of State for the Home Department, who found therein sufficient reason for the holding of an inquiry into the sanitary condition of Clerkenwell and Mile-end Old Town, and into the manner in which the local authorities of these districts have performed the duties which devolved upon them by law. The report of Mr. CUBITT NICHOLLS, the inspector appointed by the Home Secretary, has just been issued with respect to Clerkenwell, and deals as thoroughly with the subject as could reasonably be expected of a gentleman not possessing a technical medical knowledge of public health. Mr. NICHOLLS visited all the houses concerning which complaints had been made by the Council, and considered the important questions of water-supply, of regulations for houses let in lodgings, and the need for action under the Artisans and Labourers' Dwellings Act. Clerkenwell possesses a large number of tenement houses in which the landlord is not resident, as well as cottages occupied by a similar class of tenant, the total number of houses to which regulations might be made to apply being nearly five thousand. The water-supply was found in many houses to be insufficient owing to the smallness of the size of the cisterns, and often to be liable to pollution on account of the method of storage in water-butts, and the only reliable remedy which would overcome these difficulties is, the report points out, the provision of a constant water-supply. Mr. NICHOLLS further recommends the regulation of all sublet houses in which the landlord is not resident, and of some proportion of those in which the landlord is resident. With regard to the Artisans and Labourers' Dwellings Act, he mentions a number of localities in which the operation of this Act is needed. The recommendations embodied in the report are approved by two members of the vestry who were associated with Mr. NICHOLLS in the inquiry, and it may be anticipated they will be adopted by the vestry. Should this happy result be brought about, we may expect to see the death-rate of this district, which is now two in every thousand of inhabitants above that of the whole of London, reduced by that amount, and that Clerkenwell will lose the unenviable reputation which it now possesses.

The effect of the acceptance of the principles embodied in the report will not, however, be limited to Clerkenwell. For years the vestries have been fighting against the necessity for exercising the powers with which the Legislature has armed them; it may be anticipated that they will, without exception, in a short time follow the example which we presume Clerkenwell is about to set them, and that, so far as house accommodation for the poorer inhabitants is concerned, London will be free from some of the reproach which it now deserves.

It is, however, a matter for regret that the scope of Mr. NICHOLLS' inquiry was not more comprehensive. The whole of the improvements which can be effected under Sir RICHARD CROSS's Act have been omitted from consideration, the details of the arrangements for the prevention of infectious disease have been passed over, the question of the use of underground rooms as dwellings has not been raised, and certainly the need in a parish constituted like Clerkenwell of frequent inspection has not been sufficiently appreciated. Mr. NICHOLLS' opinion that two inspectors could adequately perform all the duties which would devolve upon such officers under the various Acts of Parliament will not be endorsed by those who have had practical experience of public health administration in a large town. We cannot but think that in this respect the report is unfortunate, for it is liable to be regarded by negligent authorities as an excuse for their own actions, and certainly London would not gain thereby. But, apart from this, it may be said that sanitary work in the metropolis will receive a distinct impetus from the inquiry which has been held, and the Mansion House Council are to be congratulated on the success they have already attained; but they must not regard their labours as ended until the various recommendations are carried into effect.

WE have now entered fully into the spring of another year, and the time has come when we may fairly take account of the prospects of this country with reference to cholera. For three consecutive years cholera has prevailed as an epidemic either in or upon the immediate confines of Europe. Its prevalence in Egypt in 1883 was not followed by a second epidemic in 1884; but as to this we may observe that a second year's epidemic is more apt to follow on a comparatively trifling outbreak than upon a widespread epidemic such as Egypt suffered from three years ago. In

Digitized by Google

Spain, the outbreak of 1884 was but slight; but in 1885 the disease broke out again with exceptional violence, thus following the precedents so often observed before. On the other hand, an epidemic of very fatal virulence in the south of France and in Paris during the summer of 1884 did not succeed in preventing another fatal prevalence in the same country in 1885; hence it appears that cholera does not follow any very definite laws as regards its recurrences, and in forming a judgment as to the future, we must, in the main, be guided by other considerations.

The news of the past two months supplies us with material that calls for earnest consideration. Cholera has continued to prevail in several parts of Europe during the winter months, and this week's intelligence of its recrudescence in the mining districts about Bilbao in the north of Spain comes to remind us of a real danger to this country. For months past the disease has prevailed in a more or less sporadic form along the coast of the Adriatic, between Venice and Trieste, and also further inland; and occasional outbreaks have taken place in the extreme south of Spain, and in near proximity to Gibraltar. But these occurrences do not constitute so great a danger to this country as the existence of the disease along the north coast of Spain and about the coast of Brittany, from both of which districts there is an ill-regulated traffic carried on by fishing-boats. Both these districts have been affected at intervals ever since the termination of the great epidemic of last year, and the very imperfect information we have received concerning the extent of the mischief—and this especially from the French authorities, whose mistaken policy of prevention seems mainly to lie in hushing up the truth as to the danger which exists—prevents us from knowing precisely what it is that we have to contend with. But if it should happen that an uncontrolled diffusion of infection along coasts with which we are in frequent and in near communication should follow former precedents, and this year give rise to a widespread epidemic, then a danger will have arisen which exceeds any we have as yet experienced during the epidemic of 1883-86. We must remember that the last great diffusion of cholera, beginning in the summer of 1869, had a five years' course in Europe, and that there are strong indications that the epidemics of the two preceding years are but a part of another diffusion which has not yet ended. It is therefore imperatively important that the authorities of those districts which, notwithstanding warnings and teachings such as they have never before had the benefit of, have not yet got rid of the conditions favourable to cholera diffusion, should without further delay proceed with energy, and fit themselves to cope with imported infection.

AT a meeting of the members of the medical profession residing in Glasgow and the West of Scotland it was unanimously agreed to invite the British Medical Association to hold its annual meeting in Glasgow in 1888, and it was decided that various public bodies of the city and district be requested to co-operate in the invitation.

THE supporters of the repeal of the Contagious Diseases Acts are urging upon the Government the necessity of giving facilities for taking the next stage of the measure before the 8th inst., because they feel that after that date nothing can be relied on.

Annotations.

"Ne quid nimis."

INFANT MORTALITY IN LONDON.

WITH the lapse of each year from the date of the last census the element of doubt and difficulty in the way of estimating populations detracts much from the trustworthiness of local mortality statistics. This difficulty applies with especial force to the mortality statistics of the different metropolitan sanitary areas, with regard to which the official method of assuming that the rate of increase of population since 1881 has been the same as that which prevailed between the last two censuses would in many cases lead to obviously fallacious results. The rate of infant mortality measured by the proportion of deaths under one year of age to registered births affords, however, a test of sanitary condition which is entirely free from the difficulty above mentioned. It is satisfactory to find that this test supplies evidence of the improving health of the London population. In the ten years 1861-70 the rate of infant mortality in London was equal to 162 per 1000 registered births; in the following ten years the rate fell to 158, and in the first five years (1881-5) of the current decennium it further fell to 150. The rate in 1885 was equal to 148 per 1000, and was 13 below the mean rate in the twenty-seven provincial towns dealt with in the Registrar-General's weekly return, among which the rate ranged from 128 in Hull and 131 in Brighton and in Portsmouth, to 174 in Liverpool and in Salford, 175 in Manchester, 189 in Cardiff, 193 in Leicester, and 218 in Preston. Infant mortality in the various sanitary areas of the metropolis during last year showed almost as wide a range as it did among the twenty-seven provincial towns. The mean rate in the whole of Registration London was, as above mentioned, 148 per 1000. The lowest rates in the metropolitan sanitary areas were 110 in Hampstead, 112 in Plumstead, 121 in Woolwich, 124 in St. George Hanover-square, and 129 in Lewisham. The rates ranged upwards in the other sanitary areas to 176 in the City, 180 in St. Martin's-in-the-Fields, 184 in Stepney, 190 in St. Olave (Southwark) and in St. George's-in-the-East, and 196 in Holborn. These high rates undoubtedly point correctly to those parts of the metropolis in which the social and sanitary condition of the population is most inimical to infant life, and there is little risk in assuming that the death-rates at other groups of ages in these sanitary areas would afford relatively unfavourable comparison with those prevailing in other parts of the metropolis.

THE PHYSICIAN AND HIS CULTURE.

IN his autobiography—a delightful book to be read and re-read by every aspirant to the career medical—Sir Robert Christison makes some preguant remarks on the study of Greek and Latin, and incidental observations on the attempt to supersede these languages in professional nomenclature. Traversing ground invariably occupied to a greater or less extent in the introductory lectures of our medical schools, Sir Robert runs counter to much of the advice with which on these occasions the young audiences are entertained. In reply to the contention that the study of the classical tongues "is for the most part a mere effort of rote memory, encumbering rather than strengthening the mind," he adds the weight of his experience and authority to the counter-argument, "that of all the studies suitable for boyhood there is no other which is so likely to strengthen the memory, imagination, attention, and judgment, so certain to instil taste, so useful for imperceptibly infusing an accurate and ready use of English, or so indispensable as the groundwork for acquiring modern tongues." Again, as to the assertion

Digitized by Google

that "the use of terms taken from the dead languages is the mere survival of a bad custom," and that "these terms could be expressed as easily and far more elegantly in English," it may be enough to quote what Sir Robert says of the attempt made in the latter direction by so accomplished a physician as the late Dr. Craigie:—"His practice of physic presented one novel feature, inasmuch as he tried to affix to every disease a vernacular name, which, strangely for one of his usual Latinised diction, he strove to deduce from Saxon roots. His readers may be amused with such attempts at nomenclature as 'scaly tetter' for psoriasis, 'tedious blebs' for pompholix diutinus, 'knobbed nettle-rash' for urticaria tuberosa, 'rank red gum' for strophulus confertus, 'horny fishskin disease' for ichthyosis cornea, 'prominent limpet shell scab' for rupia prominens. But no one espoused his English nomenclature, and British medicine still recognises these abominations by their Latin names only." But, in truth, Sir Robert's position is no more than that persistently maintained by men of "the complete professional mind," to use Sir Henry Acland's felicitous expression, who agree with Hamilton and Mill that even the schoolmen discharged a most useful and indispensable function in adapting and refining the delicate instrument of language, and who see no gain either to English or to science by substituting for the "impenetrability of matter" the "unthoroughfaresomeness of stuff."

CORROSIVE SUBLIMATE IN DIPHTHERIA.

DR. WERNER, medical officer to a circumscribed factory population of about 2000 near Narwa, in the Gulf of Finland, writes in the *St. Petersburger Medicinische Wochenschrift* describing the satisfactory results he has obtained in diphtheria by treatment with perchloride of mercury internally, combined with ichthyol inunctions. The disease is very frequent and fatal in the locality, he having attended during the last six years ninety cases, the average mortality of which was between 60 and 70 per cent., the majority succumbing from general weakness when the local affection was passing off or after it had quite disappeared. Last year the type was peculiarly severe. In July, August, and September eleven cases occurred, of which no less than nine proved fatal. From the end of September to the present time, however, during which period there have occurred seventeen cases, all of which were treated with perchloride of mercury, and many of which were very severe, there were only two fatal cases, neither of which was seen till a few hours before death. The author's method is as follows: For young children he dissolves a quarter of a grain of the perchloride in 4 oz. of water, for children of six or seven half a grain in 6 oz. of water, and for adults three-quarters of a grain in 8 oz. of water. This solution is given to the patients while they are awake every twenty or thirty minutes, in measured doses, so arranged that the quantities made up shall last from twenty to twenty-four hours—i.e., about half a drachm in the case of young children and a drachm in that of adults. When a good deal of sleep is obtained larger doses are given at longer intervals. As a rule only milk is allowed as nourishment. If considerable pyrexia exists, an enema of from ten to thirty grains of antipyrin, according to the age of the patient, is given, the rectum having been previously cleared out. Externally ichthyol is diligently rubbed in over the swollen glands three or four times a day, the fingers being wetted with water when dry to permit of the rubbing being continued for some time. For the first two days of this treatment the local affection usually undergoes no improvement, but on the third day it begins to diminish and the general condition becomes better, the appetite increasing and the children regaining their wonted spirits. In no case did the author meet with the extreme debility which was frequent in cases treated by pilocarpine, even when the local affection was decreasing. As the patients approached convalescence the medicine was diminished, so that more than six bottles were never required. Complications never occurred, though three of the patients had previously had scarlatina.

PAROCHIAL NEGLIGENCE.

THE long-suffering ratepayer in Marylebone has at last rebelled against the neglect of the vestry of that parish to remove his house dust. For some time the inhabitants of this district have not only been put to the greatest inconvenience, but have had their health endangered through the neglect of the sanitary authority. A complaint made by Dr. Edis to the magistrate of the Marylebone Police Court has been the occasion of an outcry which, we trust, will awake the vestry and their officials to a knowledge of the fact that there is a limit even to the endurance of the London citizen, and that if they would avoid a scandal to which their negligence has given rise they must alter their procedure. Marylebone, like many other parishes, contracts for the removal of house refuse, and hands over the dependent householder to "the mercy of a set of irresponsible dustmen, who levy blackmail and exert their petty tyranny over domestics." Dr. Edis's complaint has been echoed by his neighbours, and we are convinced that the suffering has by no means been limited to those who have joined in his protest. The householder is prohibited under penalty from permitting any other person but the parish dustman to remove his dust, and as a rule does not know of any remedy when the dustman fails to appear. But Mr. Cooke, the magistrate to whom complaint was made, has promised to grant a summons and probably impose a heavy penalty if the vestry or their officer fail to provide the necessary relief; and this promise we may be sure will not be forgotten. The foolish custom which only compels the dustman to announce his presence in the street "in an audible and distinct voice" is altogether insufficient, and nothing but a weekly call at every house should satisfy the ratepayer. The contract system is one of the worst outcomes of vestry government, and there is no practical solution to the difficulty except that the vestry should undertake the duty themselves of removing house refuse.

ON THE MOVEMENT CURE IN CHINA.

AN amusing and interesting article has been contributed by Dr. Macgowan to the Medical Reports for China for the half-year ending March 31st, 1885. P'An Wei, the present Governor of Hupeh, wrote, in 1858, a *brochure* on Important Life-maintaining Methods, which gained him much renown, causing him to be sent for on the occasion of the fatal illness of the late Empress. The accumulation of air in the system by swallowing the breath was regarded as an important method of prolonging life by the ancient Chinese. Ch'ih Sung-tzu, a legendary personage, is said to have been the author of this method; he flourished for a period of at least twelve centuries somewhere about 2600 B.C., when the Yellow Emperor sought instruction from him in the art of prolonging life. Leihtzu, the immediate disciple of Laotzu, inquired of Ch'ih Sung-tzu, the custodian of the writings of his master, how the power of traversing the air, of living unscathed in fire, and the like, might be acquired, and was told that it was neither by wisdom nor skill, but through support by the vital aura, by which was understood to mean breath-swallowing. A man who is permeated with the vital aura is invulnerable. Disease appears only when vitiated air can find entrance or when the circulation of the vital aura is defective. The air starts in its circulatory movement from the "little heart," which is situated in the pubic region.

Digitized by Google

Without fire this aura is the source of animal heat; without water it lubricates the viscera. The object of postures, motions, and frictions is to promote the due circulation of the vital air. A massage bat and massage pestle were employed in equalising the aura throughout the body; illustrations of these tools are given in Dr. Macgowan's account.

MUSCULAR ATROPHY OF CEREBRAL ORIGIN.

HEMIPLEGIA of cerebral origin is sometimes attended with decided wasting of the paralysed muscles. M. Cornil, in 1864, found that the nerve trunks in these cases had their fibrous sheaths much thickened, whilst the nerve fibres themselves were intact. M. Charcot observed in such instances that the nerve cells of the anterior horn of the spinal cord corresponding to the muscles were atrophied. This atrophy appeared to be the consequence of the propagation to the anterior horns of the inflammatory processes in the pyramidal tracts. Brissaud and others have frequently confirmed this view. M. Babiniski has put on record the following interesting instance in which the rule appears to be broken:—A woman, aged seventy, was attacked with complete right hemiplegia without hemianæsthesia; there were marked contracture and wasting, the wasting being most marked in the thenar and hypo-thenar eminences. The patient died eight months after the onset of palsy, having been all the time confined to bed. At the necropsy an area of softening was found in the left centrum ovale. There was crossed and direct descending degeneration in the spinal cord. The anterior horns, nerve roots, and nerve trunks were found to be perfectly free from any histological alterations. The muscles were much atrophied; their nuclei increased in number; the connective tissue proliferated and infiltrated with adipose tissue. The nerves and muscles of both sides were examined, so as to afford a perfect contrast. It is suggested that the process of descending degeneration in the spinal cord led to dynamic functional changes in the anterior horns and nerve fibres, and so caused the muscular atrophy without themselves undergoing the characteristic changes. Certain cases of disease of the spinal cord support this view. The case should be borne in mind in future investigations on the same subject.

THE SANITARY STATE OF NEWHAVEN.

WE are glad to find that the sanitary state of Newhaven, on which we were obliged some time since to comment adversely, is about to be dealt with by the sanitary authority, who after advertising for plans, and offering a premium for the best one, have decided to carry out an entirely new system of sewerage, according to a scheme prepared by Mr. W. H. Radford, M.Inst.C.E., of Nottingham. The scheme includes the retention of such of the existing sewers as are in good condition, the remainder being used for surface water only, and the construction elsewhere of Hassall's patent pipe-sewers, the whole system to be provided with adequate means of flushing and ventilation. The sewage from the town on the west of the river Ouse will be conveyed by a main outfall to a point away from the town, and near the mouth of the river, where it will be impounded in a concrete storage-tank during high water, the sewage being then run into the mouth of the tidal river at half ebb, so as to take advantage of a powerful current seawards. On the east of the river the present sewers and outfall at the mouth of the river will be utilised, but to prevent any backing of sewage a storage-tank, with means of flushing and ventilation, will be provided. Ultimately this outfall sewer will be connected with the previous one by means of a syphon under the river. By these several means, the impounding of sewage in the town or near habitations will be obviated, and the prevention of the passage of sewer air from the main culverts near dwellings, will be attained, and the coarse detritus will be removed from the storage-tanks before the contents enter the sea. An alternative outfall scheme, involving the construction under the chalk cliffs of a tunnel and of a well-ventilated storage-tank, has also been put forward, but whichever plan be finally adopted, the local authority feel confident that they will secure a permanent improvement in the sanitary state of the town.

PROPOSED MODIFICATION OF PIROGOFF'S OPERATION.

AT the recent congress of Russian practitioners, Professor Tauber described and demonstrated on the dead subject an operation for removal of the foot, which he believes has several advantages over Pirogoff's amputation. Standing on the outer side of the limb, he commences an incision at the insertion of the tendo Achillis, and carries it forward just below the external malleolus to the dorsum of the foot, and then vertically downwards on the inner side in front of the heel. When the middle line of the sole is reached, the incision is carried along it backwards and prolonged upwards to the starting-point at the insertion of the tendo Achillis, a flap having thus been cut consisting of the inner side and half the sole of the heel. The joint is then opened, the external ligaments being first divided and then the internal. The astragalus is seized with the bone forceps and removed, and the anterior part of the foot cut off by Chopart's line, nothing being left but the os calcis, the soft coverings of which on the inner aspect are untouched. The os calcis is seized with the bone forceps and turned so that the articular surface is towards the operator. The forceps are now taken by an assistant, who holds them tightly; the operator then saws the bone longitudinally in two; the outer half, which is free, is removed, the inner half remaining attached to the flap. The ends of the tibia and fibula are then sawn off just above the malleoli. The cut surfaces of these will be found to correspond almost exactly with that of the os calcis, which is now brought into apposition with them. The advantages claimed for this operation are: 1. The posterior tibial artery itself is untouched, only its branches being divided. 2. The insertion of the tendo Achillis, as well as its bursa, are not injured. 3. The surfaces of the os calcis and of the leg bones correspond very nearly to one another.

THE DRINK BILL FOR 1885.

IT is gratifying to know that in spite of the lamentable death of the late Mr. Hoyle we shall be favoured annually with an account of the expenditure of the United Kingdom on drink in the form of a letter to *The Times* by Dr. Dawson Burns. The great fact is a reduction in the expenditure on every kind of intoxicating liquor in 1885 as compared with 1884; on home-made spirits of £1,385,239; on foreign and colonial spirits of £180,744; and on wine of £204,190—a total reduction of no less than £3,080,496, or about 2½ per cent. Dr. Burns does not deny that this diminution is due rather to the depression of trade than to the growth of thrift and temperance. It is the best fact we know of in connexion with the depression of trade. The expenditure is still enormous and discreditable. Every man and woman should feel a personal responsibility to help to reduce it. Such an amount of alcohol can only mean great injury to liver and kidneys, bloodvessels and lungs. Medical men have a special responsibility, which we would venture to impress upon them. They are often blamed for recommending alcohol. They cannot always dispense with it, but they should think of the responsibility of the prescription.

THE MANCHESTER AND SALFORD SANITARY ASSOCIATION.

THE Manchester and Salford Sanitary Association show, by the fact that they issue a thirty-third annual report, how many years they have been labouring in the interests of public health in their district. They began their work before sanitary administrations for towns had been properly organised, and they must be regarded as pioneers in the promotion of public health work. But they still find work to do, and they continue to promote everything that may assist in the progress of sanitary science. In the face of the prospect of cholera the Association last year called together a conference, and a strong executive committee was appointed to formulate an effective scheme for combined action between the sanitary authorities, Poor-law guardians, representatives of hospitals, and others interested in the protection of the public from imported infection. A leaflet was also issued for distribution in case of the advent of cholera; and it is impossible to over-estimate the value of such an organisation, with its skilled helpers labouring in concert with the sanitary authorities in the face of any such emergency as a cholera prevalence in the vicinity of such great cities as those in question. During the year the Manchester building bye-laws received the attention of a committee of the Association, and the corporation were in the end advised to take a step which has been very widely adopted by other similar bodies—namely, to consolidate and amend their code of building bye-laws. The Association also sought to suggest a modified standard of purity under the Rivers Pollution Act, and they addressed the Local Government Board in favour of making the inspectorship under that Act an entirely separate appointment. In some respects the Association finds that duties which it originally undertook and carried out with great advantage to the public no longer call for their intervention. Thus, in the face of the staff of inspectors now acting under the health departments of Manchester and Salford, it has been thought desirable to discontinue the work of house inspection. The Association have largely aided in promoting an advanced state of public knowledge in such matters as overcrowding, house-drainage, &c., and they may now well leave the duty in question to those officials who, in addition to advising, have special facilities for enforcing the needed improvements. But no curtailing of action originally undertaken by the Association prevents them from still finding ample work; and the list of lectures already given, of duties carried out during the past year, together with the programme laid down for the attention of the members during the current year, go to show how many gaps there are in the existing organisations of public bodies which such a voluntary Association as this one can occupy with great credit to itself, and with advantage to the moral and physical welfare of the community amongst which it labours.

THE HEALTH OF RUSSIA.

IN consequence of an urgent recommendation of the Society of Russian Physicians, a special Medical Commission under the presidency of Professor Botin, was some short time since appointed by the Minister of the Interior to consider the subject of sanitary reform throughout the Russian Empire. The report of this Commission has recently been issued, and it is announced that some general measures for improving the public health are indispensable in view of the excessive mortality, which is higher than that of any other country in Europe. The creation of a central administration of medical control over the public health, in which all the sanitary questions of the Empire are to be considered, is strongly advised. With reference to the paucity of medical men, it is stated that for a population of over 90,000,000 there are only 5200 medical men—1600 under the Minister of the Interior, 1000 engaged by the zemstov, and 2600 in private practice. No greater proof, perhaps, of the unhealthiness of St. Petersburg could be given than the fact that during the month of January last no fewer than 2704 persons died (1536 males and 1168 females), while the births for the same period amounted to 1314 boys and 1286 girls only—2600 altogether—or 104 less than the deaths. Such a rate of mortality as this fully justifies the increasing concern felt in Russia as to the necessity for sanitary reform, not only in the capital, but throughout the country.

SIR WILLIAM TURNER.

No more fitting honour has been bestowed on the profession of medicine of late than the knighthood of Sir William Turner, the worthy successor of the immortal Goodsir. The compliment can be justified by reference either to Sir William's contributions to the science of anatomy or to his services to the famous University of which he is a distinguished professor and ornament. There are few present members of the Senatus to whom the University of Edinburgh owes so much as to Professor Turner. We have not always agreed with Professor Turner in his views of the true interests of the Scottish Universities and of the best way to advance them. We have seriously differed from him. But this does not hinder us from offering him our heartiest congratulations, and wishing him a long continuance of the happiness which he enjoys in the success of his own labours, and in the fame of the University which he has done so much to promote.

PERIPHERAL NEURITIS IN TUBERCULOSIS.

THAT many neuro-muscular affections of obscure origin, but hitherto suspected without proof to be due to central lesions, are unquestionably dependent upon affections of the nerve-trunks themselves, has now been well established by the accumulated facts concerning peripheral and multiple neuritis. The same lines of inquiry are leading to the overthrow of many a case attributed to "functional" derangement. This has never been better illustrated than in a paper by Drs. Pitres and Vallard, to be found in the current number of the *Revue de Médecine*. Their subject is the nerve derangements which complicate the course of tuberculosis. Apart from obvious extension of the tubercular inflammation to the brain and spinal cord, there are numerous instances, especially among the phthisical, of hyperæsthesia and of anæsthesia, of neuralgiæ of various regions, of localised muscular atrophy, of vaso-motor disturbances, which have hitherto received no satisfactory explanation, or rather, we might say, which have not been sufficiently studied. The authors named have examined the peripheral nerves in several cases of phthisis so complicated, and have found undoubted evidence of parenchymatous neuritis. In some cases, indeed, the lesions and symptoms are so widespread and severe as to closely resemble the multiple neuritis due to alcoholic poisoning; and it is not always possible to exclude this etiological factor from the case. The conclusions at which MM. Pitres and Vallard arrive are stated as follows: 1. In the course of tuberculosis, as in that of other infective diseases, it is not rare for the peripheral nerves to become the seat of parenchymatous changes having the characters of so-called degenerative neuritis. 2. These forms of neuritis are local, and do not depend upon pre-existing lesion of the brain or cord. They are to be met with in subjects whose nerve centres (brain, cord, meninges) and spinal nerve roots are perfectly intact. 3. They may attack indifferently the sensory, motor, or mixed nerves; and may similarly involve the cranial nerves (optic, oculo-motor), the pneumogastric, the

Digitized by Google

phrenic, &c. 4. Their very complex and variable symptomatology is as yet but incompletely known. It is, however, possible to divide them into three groups. The first comprises cases where the neuritis discovered post mortem has been unsuspected during life owing to the serious symptoms due to the development of the tuberculosis (latent neuritis). The second comprises cases in which localised or diffuse muscular atrophy constitutes the predominant symptom (amyotrophic neuritis). The third includes cases in which sensory disorders are produced, as hyperæsthesia, anæsthesia, neuralgia, &c. (painful or anæsthetic neuritis). 5. The frequency of peripheral neuritis in the tuberculous, the variability of its distribution, and consequently of its symptomatology, explain the occurrence and clinical polymorphism of the nervous derangements which arise in the course of tuberculosis.

IN MEMORIAM: DR. AUSTIN FLINT.

WE have been favoured with a copy of the memorial circular in which the Executive Committee of the New York Medical Association express their feelings in regard to the character and death of Dr. Austin Flint. The words are so appropriate, and so well accord with our own views, that we venture to quote some of them, which, we are sure, will be appreciated in this country, where Dr. Flint's genial and lofty presence had of late become as familiar as it was welcome:—

"Professor Flint, from early manhood, has ever been an indefatigable laborer in the field of medical science, and for half a century has been one of the most accomplished teachers and writers in the profession. His varied experience, extending over different portions of our country, enabled him, on his settling in New York City, at once to take the foremost place in the profession. As a consultant he was without a peer; his calm judgment, urbane manners, and strict conscientiousness made his presence ever welcome to his brethren. As a gentleman he will be held in grateful remembrance by all with whom he came in contact. His charities were proverbial. His death will be the cause of universal sorrow, especially occurring at a time when his deliberate counsels are most needed. We can never forget that genial countenance, those cheerful words, and that buoyant disposition, which, amid the greatest of sorrows, always pointed out the ray of light affording hope."

QUARANTINE FOR THE TONKIN TROOPS.

THE French Government have evidently given way to the clamour raised by the inhabitants of Toulon against the landing of troops from Tonkin in that port, and, having regard to the sanitary state of the town, we are not surprised at the fears which have been expressed. Some steps being necessary, Dr. Proust, the inspector-general of the sanitary services, and a staunch supporter of "quarantine" detentions under the disguised name of "observation," has matured a scheme which gives promise of securing all such efficiency as can be expected. According to the *Journal Officiel de la République Française*, the two islands of Port Cros and Bagau are to serve for the purpose. The former island is one of the most westward of the Hyères group, and thereon it is proposed to intern the passengers and crew of all non-suspect vessels arriving from Tonkin for a period of six days; all patients suffering from non-infectious diseases to be kept there in proper accommodation until they have recovered. The island of Bagau is much smaller than Port Cros, immediately to the east of which it lies. Bagau is to be reserved for so-called infected vessels, this term including those on which any case of cholera has arisen, the passengers and crew being disembarked, and the vessel and other articles being disinfected. So also, any infectious case arising in Port Cros is to be removed to Bagau. But, apart from this, there is to be no communication between the two islands, which are to have altogether separate and independent administrations. It will be interesting to observe the effect of these detentions as soon as they can be organised; the more so, as the quarantine measures heretofore adopted have certainly failed to protect France from the importation of cholera by means of troops returning from the East.

LACERATION OF THE CERVIX AND ITS SYMPTOMS.

OUR gynæcological friends would command greater respect for their specialty if they would give out a little more certain sound as to uterine lesions and their significance. Every lesion seems to be in fashion for a time, and then be found out to be more or less unsubstantial, when it gives place to another. One time ulcers of the cervix were the explanation of all ills that women are heir to. These were next referred to "displacements," which in their turn gave way to ovarian and tubal inflammations, which now seem threatened by lacerations of the cervix, generally produced by long or instrumental deliveries. Dr. Charles Meigs Wilson, in an interesting paper before the Obstetrical Society of Philadelphia, attaches great importance to this lesion as a cause of unique symptoms, pelvic distress and often severe reflex nervous symptoms mounting up to insanity itself. Neglected cases of laceration often end in subinvolution, with subsequent prolapsus, hyperæmia, hypergenesis of tissue, and ectropion of the cervical mucous membrane. One patient suffering from such symptoms had them all attributed to floating kidney, and was recommended to have it extirpated. She was quite cured by having the contour of the cervix restored. Another had ulcer of the rectum with painful defecation and ribbon stools, backache, and slight vaginal discharge. She was suspected of cancer of the rectum. Specular examination of the vagina showed extensive bilateral laceration with acute retroflexion. The restoration of the contour of the cervix and simple astringent application to the rectal ulcer completed the recovery. In a third case pyosalpinx was diagnosed and oöphorectomy recommended. Extensive laceration was found, the cure of which was followed by complete cessation of all the symptoms. This patient had suicidal dementia and sometimes required restraint. Another patient was in an asylum for fourteen months. Distressing pelvic pain and profuse leucorrhœa led to the discovery of extensive laceration of the cervix, and two months after to complete recovery, which continues after twelve months. The author did not dwell on the operative treatment, but in the discussion great importance was attached to the complete removal of hard cicatricial tissue and perfect union of the coapted edges. In all cases rest and milder measures should first be tried.

BUISSON'S TREATMENT OF HYDROPHOBIA.

CENTRES have been established in various parts of London and in a few provincial towns for carrying out M. Buisson's treatment of hydrophobia. The wound is washed with a solution of ammonia; the patient has a daily vapour bath at a temperature of 42° to 48° Réaumur, with a view to producing profuse perspiration for seven consecutive days, and draughts of a hot infusion of borage, also with a view to promoting the diaphoresis. We gave a brief account of this treatment in THE LANCET of Aug. 23rd, 1884. Dr. Buisson is said to have cured himself after the development of the symptoms of hydrophobia. He and his disciples regard the method as an infallible preventive of hydrophobia, and as an equally certain cure, if begun on the first day of the developing disease; on the second day its effect is less certain, and later it has no effect in staying the course of the malady. As to the merits of the treatment we can assert nothing. It

Digitized by Google

is alleged to have prevented or to have cured the disease a hundred times. But the sources of fallacy are innumerable. We do not yet know the proportion of individuals bitten by a mad dog who become the subjects of hydrophobia. It is difficult to conceive that profound sweating can stay the course of a disease which seems to be due to the development of a living germ in the medulla oblongata. That washing a recent wound with liquid ammonia and making the individual perspire profusely should be able to prevent the disease can be reasonably conceived.

THE COMMONS MUST GO TO BED EARLIER.

IF the House of Commons cannot be induced to adopt the early-closing movement for itself by fair means, it is high time that publicly and personally most desirable reform should be effected, even though it be by means most foul. We are therefore glad to see that Mr. Blake, M.P., has written to a contemporary proposing that at twelve o'clock every night some hon. member shall rise in his place to move that any debate then in progress may be adjourned, and if this be carried that the division shall be immediately followed by a motion to adjourn the House. Mr. Blake is of opinion that a sufficiently large party to carry out this organised obstruction in the interests of health could readily be formed. We trust he is right. It would, of course, be better if the House of Commons could be placed on the footing of a public-house and compelled to close its doors at midnight. How gladly would the over-worked officials receive a standing order to lower the gas at a quarter to twelve, and to turn it off completely when Big Ben struck the last unit of the midnight hour! Let us hope Mr. Blake's revolt will succeed. The healths of our representatives and the value of their achievements alike point urgently to the need of this beneficent reform.

THE RIVER LEA.

THE Select Committee of the House of Commons appointed to inquire into the pollution of the river Lea has commenced its work, and has received the evidence of Mr. George Corble, the clerk to the Lea Conservancy Board, who gave an account of the Acts of Parliament relating to the rivers Lea and Stort. The Conservancy Board have, it appears, a prior right under the Act of 1855 to the use of the water, but they had not exercised this right to the full because they had been unwilling to interfere with the water companies who were dependent upon this source for their supplies. Mr. Corble believed the condition of the river, which last year was the subject of serious complaint, was due to the Tottenham effluent; and while he admitted that if the Conservancy Board had fully exercised their rights this condition would have been better, he did not know what the East of London would have done had the East London Water Company been deprived of its water.

LIGATURE OF THE INNOMINATE ARTERY.

MR. BENNETT MAY ligatured the innominate artery, under the spray, for a large subclavian aneurysm, at the Queen's Hospital, Birmingham, last Saturday morning. The patient, aged thirty-three, is a labourer in a large brewery, and has been accustomed to lift heavy weights on to his right shoulder. This joint has been three times dislocated, and symptoms of the arterial mischief first appeared eighteen months ago. Since the operation the patient's constitutional state has been most satisfactory. The temperature only rose slightly above normal on the fourth day. In tying the vessel Mr. May used a cord made up of six strands of carbolised catgut, and employed sufficient force to arrest all pulsation in the tumour, without, however, severing the coats of the vessel, which was much dilated. No pulsation could be felt at the right wrist when the patient left the operating theatre, but it reappeared slightly the same evening, and has since continued.

THE LATE DR. GEORG VARRENTRAPP OF FRANKFORT.

DR. GEORG VARRENTRAPP, who died at Frankfort-on-the Main on March 15th, at the age of seventy-seven, was one of those who have been most successful in drawing the attention of the public to the necessity of sanitary measures. He rendered great service to school hygiene both by his writings and as a member of the governing body; but his chief work was the carrying out of an improved system of drainage in his native town of Frankfort. He was the first to found a sanitary journal in Germany, and the eighteenth volume of this periodical is now in course of publication. His student days were passed at Würzburg, where he graduated in 1831, since which time he lived and practised in Frankfort, where he held the appointment of physician to the Hospital of the Holy Ghost.

WELL DONE SUNDERLAND, NORWICH, AND HUDDERSFIELD!

A HIGHLY creditable fact in vital statistics will have been noticed in an abstract of the Registrar-General's reports last week—viz., that in Sunderland, Norwich, and Huddersfield there was not recorded one death from any of the principal zymotic diseases—whooping-cough, measles, diarrhœa (interesting to notice diarrhœal deaths even in such a cold March as we have had), scarlet fever, fever, diphtheria, and small-pox. These towns have a population respectively of 116,542, 87,842, and 81,841—in all of 286,225. Sunderland, at least, has severely felt the incidence of the commercial depression. The low zymotic mortality which we emphasise is only the more creditable to the municipal and medical authorities of these towns, and enlarges our views of the possible results of sanitation and of medicine in reducing the mortality of communities.

TYPHUS IN MOSCOW.

SPOTTED TYPHUS was so prevalent in Moscow last month that, according to the *Russkaya Meditsina*, in spite of 150 temporary additional beds in the hospitals, patients had to be refused admittance for want of room; and the latest Moscow journals say that, this state of things continuing, it has been arranged to send all patients with chronic and incurable diseases out of the hospitals in the town. In this way some 500 beds will be available for typhus cases. The patients sent out will be provided for elsewhere. It is also stated that even in the Government prisons the disease is raging pretty severely.

THE IDIOTS BILL.

THE framers of this measure should at once determine, not only in their own minds but by an intelligible definition of the term "idiots," what class of persons they intend to deal with. As the Bill is drawn it is a highly unsatisfactory measure, affording opportunities for dealing with persons of feeble mind with only one certificate instead of two, and with the least possible protection. It will be a scandal if this measure passes with no more attempt to distinguish between two classes extremely easily confounded than the absurd intimations that "'idiots' or 'imbeciles' do not include lunatics," or "'lunatic' does not mean or include idiot or imbecile." The definition is not one whit more intelligible as a means of analysis than the famous synthetical formula, "Cæsar and Pompey are alike, especially Pompey."

Digitized by Google

DR. TEJADA Y ESPANA.

THE death is announced of Dr. Tejada y España, editor of *El Genio Médico*, one of the weekly medical journals published in Madrid. He began his career as a "third-class surgeon" in the province of Burgos, and there became editor and proprietor of the *Eco de los Cirujanos*. He afterwards went to Madrid and took the degree of Licentiate in Medicine, which was succeeded by that of Doctor. Of two older medical journals which he edited he founded the *Genio*, which is now in its thirty-second year. He wrote also a Compendium of Surgery and a well-known novel, "*El Coche del Médico*" ("The Doctor's Carriage"). He was an honorary member of a considerable number of foreign scientific societies.

FOREIGN MEDICAL APPOINTMENTS.

PROFESSOR F. A. HOFFMANN of Dorpat has been appointed to the charge of the Leipsig Policlinic, vacated by Professor Strümpel, who has gone to Erlangen; Professor Dr. Richard Wiedermann, the physicist, succeeds Professor Dorns. Professor Lommel of Erlangen has been appointed to the Chair of Experimental Physics at Munich. Dr. Otto Haab, assistant in the Ophthalmic Clinic, has been appointed to the Professorship of Ophthalmology at Zürich, vacated by Professor Horner. M. Wasseige, a professor in the Medical Faculty of the University of Liege, has been appointed Rector, and received quite an ovation from the medical students and from his colleagues. He was at the same time raised to the dignity of Officer of the Order of Leopold.

A LARGE FEE AND A MUNIFICENT DONATION.

WE understand that the sum of £5000 has been entrusted to Sir Andrew Clark by a lady as a donation to medical charities. This sum he has distributed as follows:—£2000 to the London Hospital; £1000 to the Medical College attached to that hospital; and £2000 to the Royal Medical Benevolent College. The presentation was preceded by the payment of a fee of £1500 to Sir Andrew in consideration of his absence ~~from town for five days~~ on a professional visit to this lady in the South of France.

THE PASTEUR TREATMENT OF HYDROPHOBIA.

THE Academia Medica di Roma on Sunday, March 28th, Professor Guido Baccelli presiding, held an animated discussion on M. Pasteur's method in hydrophobia. Opinion as to its efficacy was much divided, and the discussion was adjourned till April 4th, when a decision will be come to, and a report prepared for publication in the Academy's official organ, the *Bollettino*.

FROM the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during the month of February, it appears that the Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies contained in every case less organic matter than was present in the January samples, and in none of the samples was the organic matter excessive for this season of the year. Of the water drawn from the Lea, that supplied by the New River Company contained less, and that by the East London Company more, organic matter than any of the other river waters. All the samples were clear and bright on delivery.

THE Senate of the University of Edinburgh has offered the honorary degree of LL.D. to Deputy Inspector-General F. J. Mouat, M.D., F.R.G.S., &c.

IN the *Vierteljahresschrift für Dermatologie und Syphilis* Professor J. Caspary, of Konigsberg, figures one of two children, aged respectively four years and a year and a half, affected with ichthyosis fœtalis. They were the children of cousins, and were prematurely born. There seems to be no doubt that the affection was congenital; but the state of the skin did not quite correspond to that in the harlequin fœtus lately shown, brought by Mr. Sutton to the Royal Medica and Chirurgical Society. There were, however, flexion of the limbs and genu valgum. Professor Caspary gives some interesting references to other cases, entirely, however, from German literature, and discusses the relation of the condition observed with that of the so-called harlequin fœtus.

THE *Presse Médicale Belge* announces that the Council of Administration of the University of Brussels has actually ratified "the deplorable decision" of the Faculty of Medicine, which has the effect of depriving Professor Crocq of his chair of clinical medicine and of his examinership in the practical part of the examination for the M.D. degree.

THE Government of Spain have information to the effect that suspicious cases of illness have occurred in the mining district of Bilbao, and that two cases have been pronounced to be cholera. A later account contains the usual denial, but it will be recollected that the disease prevailed in this locality late during the course of last autumn.

THE Archduke Charles Theodore of Bavaria, who practises medicine, has obtained permission from M. Pasteur to be present at the inoculations in the laboratory of Rue d'Ulm. The Archduchess, who helps her husband in his professional labours, will accompany him as an assistant.

THE Gresham Lectures will be delivered by Dr. Symes Thompson on April 6th and three following days, the subject being the "Diseases of Infancy and Childhood."

SCHROEDER'S Treatise on Diseases of the Female Genital Organs has just been translated into French by two Belgian physicians, MM. E. Lauwers and Hertoghe.

Pharmacology and Therapeutics.

IMPROVED GELATINE LAMELS.

THESE lamels are prepared by Mr. Brownen and are designed to meet the requirements of modern surgery and medicine. It is asserted that the lamels or discs are prepared with the purest gelatine and are so manufactured as to be free from every impurity, including fungi and germs. Three of the lamels are now official in the British Pharmacopœia of 1885—atropine, physostigmine, and cocaine. The lamels are made for use in ophthalmic surgery, as well as for hypodermic medication. The specimens that we have submitted to trial have answered their purpose admirably. The articles may be procured of Mr. Martindale, 10, New Cavendish-street, W.

PHYSIOLOGICAL AND CLINICAL BEHAVIOUR OF ANTYPYRIN AND THALLIN.

Our knowledge of the action of the new antipyretics is receiving constant, we may almost say weekly, additions. One of the latest researches on these drugs is by Dr. Anseroff, and is reported in the *Russian Medical Review* for last month. The particular point to which he directed his investigations, which were conducted both in the laboratory and in the wards, was the effects of antipyrin and thallin on the vaso-motor apparatus both in the normal state and in fever cases. He employed for some of his experiments

Digitized by Google

animals which were sufficiently under control not to require tying-up, which of itself must exert some influence prejudicial to the results. He found that antipyrin caused an increase of blood-pressure and a decrease of the internal temperature, as shown by a thermometer in the rectum; but a considerable rise, sometimes as much as 12°C., in the external temperature, that of the paw being generally taken. This rise of the temperature of the paw, however, did not occur where the limb had been previously paralysed by division of the sciatic nerve, showing that the antipyrin acted as a stimulant to the vaso-dilator nerves through the vascular centre, the vaso-constrictors of the interior being stimulated so that the tension remained above the normal. Similar results were given by experiments with thallin. With regard to the rise of temperature which sometimes occurs after the exhibition of considerable doses, Dr. Anseroff suggests that increased loss of heat may induce augmented heat formation. The rise observed after thallin may be explained by the exhaustion of the apparatus which regulates the loss of heat. Clinical observations on fever patients present an analogous result—viz., a lowering of the internal temperature going on side by side with an increase of the external temperature. Clinically, the following points concerning the two drugs should be borne in mind. 1. With thallin the temperature begins to rise again two hours after the dose. 2. Very frequently a single four-grain dose of thallin produces a rigor with a subsequent rise of temperature, sometimes above that which existed before the medicine was taken. 3. With respect to equal doses of the two drugs, thallin causes a more decided reduction of temperature, but is much more likely to produce a rigor with a subsequent rise. Antipyrin behaves, in the author's opinion, like hydro-therapeutic measures in improving the breathing, pulse, general feeling, and appearance of the patients.

PIPER METHYSTICUM (KAVA-KAVA).

A substance, the active principle of kawa, appears to possess more qualifications as a substitute for cocaine than either menthol or apomorphine, if we may speak thus from purely experimental researches, the results of which M. Lewin of Berlin has recently collected in a *brochure* published by A. Hirschwald. The plant is already known to the medical world under the name of kava-kava; the root has been used by the inhabitants of the Polynesian isles in the preparation of an intoxicating liquor which is their alcohol; it is also employed to check discharges from the urethra and other parts. Two crystallisable substances, kawahin and yankonin, have been separated from the root by Nölting and Kopp. By agitating the root with petroleum ether M. Lewin has extracted two resinous bodies: one (*a*) of these has a greenish-yellow tint and the odour of the plant; the other (*b*) has a reddish-brown colour. A minute particle of the two resins, or of the first, placed on the tongue causes a sensation of burning, which is followed by a certain degree of anæsthesia of the part touched. The anæsthetic effect is said to be well marked on the conjunctiva, and may be prolonged for hours in guinea-pigs by renewing the fragment of resin from time to time; the eyes underwent no pathological alteration, only a slight dilatation of the palpebral fissure. The introduction of minute quantities of the resin (*a*) under the skin of frogs produces marked loss of sensibility, so that the animal takes no notice of severe irritation of the affected part; ligature of the vessels of the limb experimented on made no difference in the result; the local anæsthesia continued to be local. Introduced into the subcutaneous tissue of rabbits the anæsthesia developed without any sign of inflammation. Kawa resin appears to exert a paralysing influence when administered in larger doses, and its effect in this regard is thought to be due to its action on the motor cells of the anterior horn of the spinal cord. Its first action is believed to be on the terminations of the sensory nerves. M. Lewin suggests that it also destroys the conductivity of fibres, conveying painful impressions in the grey matter of the cord; and he also thinks it acts on the brain, causing sleep.

COCAINE.

A case has been recorded by Dr. Schilling in the *Pharmaceutical Journal* in which the injection of six drops of a 20 per cent. solution of cocaine into the gums of a woman aged twenty-eight, to prevent the pain of extraction of a molar tooth, was followed after the extraction by symptoms of which unconsciousness and rigid aspect of the face were the chief. There was contraction of the retinal arteries, as witnessed by the ophthalmoscope. The inhalation of three drops of amyl nitrite restored the patient to consciousness, and it was considered probable that the brain was in the same anæmic state as the retina. Dr. Bignon says that cocaine, if it be pure, should be white, almost inodorous, entirely soluble in three parts of alcohol, two parts of sulphuric ether, in chloroform, in sulphide of carbon, and in twenty parts of tarzine, prepared either from tar or petroleum. According to him, also, the benzoate of cocaine is more stable than the hydrochlorate, and is preferable in other ways. Grunhagen and Berthold have ascertained that injections of cocaine in moderate doses increase the blood-pressure, and they believe that this result is to be attributed to an excitation of the vaso-motor centre, since it does not occur after section of the cervical swelling of the spinal cord. In larger doses a fall in blood-pressure takes place, due to paralysis of the vaso-motor centre; in a curarised rabbit whose vagi were cut in the neck after having received a large dose of cocaine, with consequent lowering of the blood-pressure, stimulation of the saphenous nerve caused no augmentation of blood-pressure until the effect of the cocaine had passed off.

HOMERIANA.

A plant called Homeriana (Palygonum aviculare), which is very common in Russia, and is used popularly as a drug, has been examined by Dr. Rotschinin and reported on in a paper read to the recent congress of Russian doctors. It has been found by Werner to contain a large proportion of alkaloid. A decoction, however, was used by Dr. Rotschinin, a tumblerful being given three times a day. It appeared to be really valuable in several cases of bronchitis, two of which were capillary; also in three cases of whooping-cough. It was tried in phthisis but no definitely satisfactory results were obtained.

GRINDELIA ROBUSTA.

The action of grindelia robusta has been investigated by L. Grimvetski, his paper on the subject being published in the *Russkaya Meditsina*. He found the liquid extract very useful in emphysematous asthma due to chronic bronchial catarrh, the asthma diminishing after a few doses, and the cough and expectoration likewise becoming less. His prescription was—"℞ Inf. rad. senegæ, ʒvi.; ext. grindel. robust., ʒij. to ʒiij.; syrup. glycyrrhizæ, ʒss. A dessertspoonful every two hours till relief is obtained." It was found that the drug was useless in asthma due to other causes.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Reading Urban District.—The death-rate for this borough during 1885 was 18·0 per 1000, and the zymotic rate 2·6. The inhabitants number somewhat over 42,000, and the population per acre amounts to 22·4. Amongst the deaths from infectious diseases there were 58 from measles, and 22 from whooping-cough. In short, a large number were beyond the present range of sanitary measures. But there were 19 deaths from scarlet fever; and in the absence of a proper hospital for the reception of such cases, it appears that in two instances only was removal effected to the small cottage at present available for isolation purposes. Diphtheria is known to have occurred in 21 cases, and 9 of the attacks proved fatal. Diarrhœa was, fortunately, almost entirely absent as a fatal disease. Sanitary work is steadily progressing; the houses still needing it are continuously being connected with the new system of public sewers, fresh bye-laws have just been finally dealt with, and the imperfect system of hand flushing to waterclosets has been replaced by cistern flushing in 236 cases. But in 24 instances there is direct communication between the closet pans and the water mains, and, knowing the extreme danger of this arrangement, Dr. Shea presses for the abolition of all such connexions.

Kettering Urban District.—Mr. Dryland reports the condition of this district as remaining satisfactory, there having been no epidemic, the general death-rate standing at 15 per 1000, and the infant mortality having diminished. The

Digitized by Google

attention heretofore devoted to the perfecting of house, drain arrangements continues, and alterations are insisted on whenever nuisance or injury to health enables the authority to act. The old infectious hospital being dilapidated, a new permanent hospital is now about to be erected outside the town, and the new sewerage works are completed. Altogether this urban district has, for some years past, shown signs of steady sanitary progress.

Wellington Urban District.—Dr. Meredith reports that, notwithstanding a somewhat fatal epidemic prevalence of measles, the death-rate for 1885 amounted to only 15 per 1000. A scarlatina prevalence, which fortunately was of a mild type, became a good deal diffused amongst children attending the various schools; and under these circumstances it was found necessary to exclude children in affected houses from school attendance. As to this prohibition under the Education Code, the report points out how difficult it is to prevent children from mingling at play. This is true; and the medical officer of health who avails himself of this system of exclusion from school of children from special districts or houses, instead of resorting to the alternative of closing the school altogether, will always necessarily have to judge whether, under the local circumstances, he will best gain his end, of securing the utmost practicable isolation, by the one or the other process.

Doncaster, Goole, &c., Combined District.—In preparing his annual report on this combined district, Dr. Mitchell Wilson takes occasion of the issue of the Registrar-General's decennial report to make comparison for the past ten years between the districts in his combination and England and Wales as a whole; and these go to show a marked and progressive diminution in mortality, which may, in large part, be properly attributed to the sanitary work which has been carried out. In the *Doncaster Rural District* the death-rate for 1885 was 16 per 1000. Amongst the infectious diseases which prevailed were diphtheria, small-pox, and enteric fever, which led to sanitary improvements being effected; but it is evident that in certain localities the need for an improved water-supply still calls for remedy. Some important work has, however, been accomplished, such as the sewerage works for Balby-with-Hexthorpe; and the list of minor duties performed go to show that a good deal of beneficial work is steadily in progress. In the *Goole Rural District* there was a low mortality of 15·3 per 1000 and an absence of any serious outbreak of infectious disease. In the marshland districts the question of water-supply is one of considerable difficulty, for those supplies which are immediately procurable are brackish and unwholesome, and the expense of providing any other supply than that of rain from roofs would be very costly for such a district. Considerable attention is being given to the subject, but for various reasons no solution has yet been arrived at. In the *Selby Rural District* the death-rate of 18·4 per 1000 exceeded the average rate for the previous five years, but the zymotic rate of 1·3 was not heavy. Small-pox caused some mortality, and enteric fever was locally spread by impure water and defective drainage. Referring to sanitary work, Dr. Wilson reminds his authority that its value is not necessarily to be judged by the cost, and that much of the comparatively costless work which is continuously being done in the district forms a very important part of the sanitary administration carried out. A large improvement has been effected in connexion with the water-supply, and eighty new wells have been sunk during the past five years. In the *Tadcaster Rural District* the annual death-rate was 18·2 per 1000, and the rate from the zymotic diseases was as high as 3·4 per 1000. Scarlet fever was prevalent in Kippax and at Garforth. Enteric fever began and spread at South Milford through the use of brook water, which receives sewage not only direct from drains, but also indirectly by soakage from foul ash-pits. But on the whole there has, during the past five years, been a satisfactory diminution in the prevalence of continued fever, and in this connexion it is to be noted that polluted water-supplies have been extensively dealt with. A proper system of drainage and water-supply are much wanted at Kippax, but at Garforth, Micklefield, and at Great Preston sanitary works of importance were carried out. The *Goole Urban District* exhibited a death-rate of 15 per 1000 only, and the cases of infectious diseases reported were comparatively few in number, the hospital being, however, utilised for cases of small-pox. Strict supervision was maintained during the year under the Canal Boats Act, but as regards the respective duties of Hull and Goole at the entrance of the river matters are not very satisfactorily arranged to meet any danger from imported cholera. The scavenging of ash-pits and tub-closets still remains to be efficiently dealt with, and so far as we can judge, the only proper solution of the difficulty would be for the local authorities to organise a staff of their own to do it. During the past ten years 128 patients have been admitted to the fever hospital, and considering that it is but a workhouse establishment transferred to the sanitary authority, this result is by no means unsatisfactory. The death-rate in the *Selby Urban District* amounted to 18·5 per 1000. Dr. Wilson devotes a good deal of attention to the need which exists in this district for some proper provision for the isolation of infectious fevers, and it is to be hoped that his arguments will not pass unheeded. Last year saw the completion of a new water-supply for Selby, as also new bye-laws for regulating streets and buildings. The slaughterhouses are well looked after, the common lodging-houses are regularly inspected, and sanitary work is continuously maintained.

Cranbrook Rural District.—Mr. Butterfield is able to point to a continued small mortality in this district. The mean rate for the ten years ending 1884 was 15·5 per 1000, and that for 1885 is 15·7; the zymotic rate is also low—namely, 1·2 per 1000. New sewers have been constructed, which have secured the efficient drainage of 140 houses, polluted wells have been closed, and a few cases of infectious disease have been dealt with by a system of trained nursing which aims at the utmost procurable isolation together with disinfection. But there is one drawback to this district. The state of Cranbrook is such that it is described as surrounded by its own sewage, and it is urged that when the water-supply is drawn from the proximity of cesspools a catastrophe must be expected sooner or later, and that bad times are no sufficient argument to justify the postponement of the necessary remedial works.

Lincoln Rural District.—Subject to corrections necessary for public institutions, the death-rate for 1885 was 15·5 per 1000. The only disease which prevailed with sufficient intensity to call for special notice was diphtheria, and a somewhat large outbreak beginning with, and being spread by, so-called cases of quinsy and sore-throat, took place during the year. It was associated with conditions which call for substantial action on the part of the authority, such as overcrowding, want of proper drainage, cesspools overflowing into ditches and a beck, and slops and heaps of refuse lying about. But it was not found practicable to exercise sufficient care in connexion with school attendance, and it would be well for Dr. Harrison, after securing the co-operation of the school officials, to enforce for some time to come a rigid exclusion of all scholars from houses where sore-throat of any sort prevails. It has in some districts been found most useful to organise a roll-call at the beginning of every day's school as to such affections in the houses from which children came, and then to get the authority to put in force the exclusion clause of the Education Code. Diphtheria has caused 46 deaths in this district during the last ten years, and in 1882 and 1884 the fatal attacks were eleven and ten respectively.

Spennymoor Urban District.—This coal and iron district, with some 6000 inhabitants, has never been distinguished for activity in its sanitary work, and this notwithstanding the fact that its defects have been pointed out by the local officer of health and special medical inspectors. In 1885 the death-rate was needlessly high for so small a population—viz., 20·3 per 1000. Dr. O'Hanlon reports that many causes of disease still exist in this district, and amongst these he enumerates the following: (1) The influx of pitmen and others from infected districts, seeking work; (2) the unhealthy conditions of middens and privies; (3) the excessive use of intoxicating liquors; (4) the chewing of tobacco, and the drinking of laudanum amongst the women; (5) the ill-feeding of children; (6) the great neglect of children; and (7) the gossiping amongst women during the prevalence of epidemic diseases. Unless Spennymoor has materially altered within the past few years, and there is no evidence of this, the sanitary circumstances by which the populations are surrounded, and under which young people live, are calculated, to a large extent, to give rise to demoralising influences, and to bring about the very conditions for which the place is said to be noted. If the sanitary authority would only try it, they would find that the educational effect of perfect cleanliness of thorough-

Digitized by Google

fares, yards, spaces about houses, and inside dwellings would probably do more than anything else towards removing those causes of death to which the medical officer of health refers.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6183 births and 4603 deaths were registered during the week ending March 27th. The annual death-rate in these towns, which had steadily increased in the eight preceding weeks from 22·1 to 29·3, declined again last week to 26·4. During the first twelve weeks of the past quarter the death-rate in these towns averaged 24·4 per 1000, and exceeded by 0·2 the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 18·3 in Hull, 19·6 in Sunderland, 20·2 in Newcastle-upon-Tyne, and 22·2 in Wolverhampton. The rates in the other towns ranged upwards to 30·9 in Preston, 31·0 in Manchester, 37·3 in Blackburn, and 40·2 in Plymouth. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 430 and 427 in the previous two weeks, further declined last week to 406; they included 164 from whooping-cough, 128 from measles, 32 from diarrhœa, 28 from "fever" (principally enteric), 28 from diphtheria, 22 from scarlet fever, and 4 from small-pox. No death from any of these zymotic diseases was recorded last week either in Derby or in Halifax; whereas they caused the highest death-rates in Bolton, Portsmouth, and Blackburn. Whooping-cough caused the greatest mortality in London, Leicester, and Portsmouth; measles in Birmingham, Nottingham, Portsmouth, Bolton, and Blackburn; and scarlet fever in Birkenhead. The 28 deaths from diphtheria in the twenty-eight towns included 18 in London, 2 in Liverpool, and 2 in Wolverhampton. Small-pox caused 2 deaths among the residents of London and its outer ring, 4 in Bristol, and not one in any of the twenty-six other large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 7 on each of the preceding three Saturdays, was 8 at the end of last week; 5 cases were admitted to these hospitals during the week, against 1 and 2 in the preceeding two weeks. The Highgate Small-pox Hospital contained 5 patients on Saturday last, 2 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had increased in the preceding nine weeks from 477 to 917, declined last week to 710, but exceeded the corrected weekly average by 202. The causes of 82, or 1·8 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Birmingham, Bristol, Preston, Plymouth, and Halifax; and the largest proportions of uncertified deaths were registered in Salford and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the preceding five weeks from 22·3 to 27·9 per 1000, declined again to 24·7 in the week ending March 27th, and was 1·7 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 13·9 and 14·8 in Greenock and Leith, to 30·4 in Paisley and 30·5 in Glasgow. The 609 deaths in the eight towns showed a decline of 81 from the number in the previous week, and included 29 which were referred to whooping-cough, 11 to diarrhœa, 8 to measles, 8 to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 1 to diphtheria, and 1 to small-pox; in all, 62 deaths resulted from these principal zymotic diseases, against 51 and 46 in the preceding two weeks. These 62 deaths were equal to an annual rate of 2·5 per 1000, which exceeded by 0·2 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 20 and 14 in the preceding two weeks, rose last week to 29, and included 27 which occurred in Glasgow. The 11 deaths attributed to diarrhœa corresponded with the number in each of the previous two weeks, and included 7 in Glasgow. The 8 deaths from measles were within two of the number in the previous week; 7 occurred in Edinburgh. The fatal cases of scarlet fever, which had been 5 and 4 in the preceding two weeks, rose last week to 8, of which 5 were recorded in Glasgow and 2 in Edinburgh. Two of the 4 deaths from "fever" occurred in Glasgow. The death from small-pox was returned in Edinburgh. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had steadily increased in the preceding seven weeks from 135 to 204, declined last week to 148, but were 26 above the number returned in the corresponding week of last year. The causes of 53, or 8·7 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 30·1, 38·3, and 40·5 per 1000 in the preceding three weeks, declined again to 34·6 in the week ending March 27th. During the first twelve weeks of the past quarter the death-rate in the city averaged no less than 33·5 per 1000; the mean rate during the same period did not exceed 25·1 in London and 20·0 in Edinburgh. The 234 deaths in Dublin last week showed a decline of 40 from the high number returned in the previous week, and included 18 which were referred to the principal zymotic diseases, against 19 and 13 in the previous two weeks; 12 resulted from whooping-cough, 4 from diarrhœa, 1 from "fever," 1 from scarlet fever, and not one either from small-pox, measles, or diphtheria. These 18 deaths were equal to an annual rate of 2·7 per 1000, the rates from the same diseases being 2·6 in London and 2·5 in Edinburgh. The fatal cases of whooping-cough, which had declined in the preceding four weeks from 18 to 6, rose again last week to 12. The deaths referred to "fever" (typhus, enteric, or simple), on the other hand, declined from 6 in each of the previous two weeks to 1. The 4 deaths attributed to diarrhœa showed an increase upon the numbers in recent weeks. Five inquest cases and 7 deaths from violence were registered; and 69, or considerably more than a quarter of the deaths, were recorded in public institutions. The deaths of infants showed a considerable decline, while those of elderly persons had increased, and exceeded the number in any previous week of this year. The causes of 30, or nearly 13 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Grenadier Guards: Surgeon-Major F. B. Baker is placed on retired pay with the honorary rank of Brigade Surgeon; Surgeon George B. Stuart, M.B., to be Surgeon-Major, vice F. B. Baker, retired.

ARMY MEDICAL STAFF.—Surgeon-General Grahame Auchinleck, M.D., has been placed on retired pay; Brigade Surgeon Oliver Codrington, M.D., is granted retired pay, with the honorary rank of Deputy Surgeon-General; Surgeon-Major William Robertson, M.B., is granted retired pay, with the honorary rank of Brigade Surgeon; Deputy Surgeon-General William Arthur Thomson, M.B., to be Surgeon-General, vice Grahame Auchinleck, M.D., granted retired pay; Deputy Surgeon-General Edward Malcolm Sinclair, M.D., from half-pay, to be Deputy Surgeon-General, vice William Arthur Thomson, M.B., promoted. Brigade Surgeon Edmund Greswold McDowell, C.B., to be Deputy Surgeon-General, vice Alexander Guthrie, M.D., deceased.

ADMIRALTY.—Royal Naval Artillery Volunteers, Clyde Brigade: John Gray McKendrick, M.D., LL.D., F.R.S., to be Honorary Staff Surgeon.

YEOMANRY CAVALRY.—Lancashire Hussars: Surgeon Edward Henry Beaman resigns his commission.—Middlesex: Edward Stewart, Gent., M.D., to be Surgeon.

ARTILLERY VOLUNTEERS.—3rd Middlesex: Surgeon Edward Godfrey Purcell is granted the honorary rank of Surgeon-Major.—3rd Lancashire: Michael John Fox, Gent., to be Acting Surgeon.—2nd Middlesex: Surgeon Thomas Thyne, M.D., is granted the honorary rank of Surgeon-Major.

ENGINEER VOLUNTEERS.—2nd Gloucestershire (the Bristol): George Munro Smith, Gent., to be Acting Surgeon.

RIFLE VOLUNTEERS.—3rd (the Buchan) Volunteer Battalion, the Gordon Highlanders: Alexander Forbes Trail, Gent., M.B., to be Acting Surgeon.—1st Berwickshire: James Duncan Jeffrey, Gent., to be Acting Surgeon.—2nd Glamorgan: Captain Edmund Samuel Warburton to be Acting

Digitized by Google

Surgeon.—3rd Lancashire: Surgeon John Burns is granted the honorary rank of Surgeon-Major.—6th Suffolk: Acting Surgeon William Thomas Angove resigns his appointment.—2nd Wiltshire: Surgeon and Honorary Surgeon-Major Charles Hitchcock, M.D., resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement.—2nd Volunteer Battalion (the Gloucestershire Regiment): Arthur Fowell Turner, Gent., to be Acting Surgeon.—1st Dorsetshire: Surgeon Robert Godolphin Long resigns his commission; also is granted the honorary rank of Surgeon-Major and is permitted to continue to wear the uniform of the corps on his retirement.—3rd Durham (the Sunderland): Robert John Collie, Gent., M.D., to be Acting Surgeon.—3rd Volunteer Battalion (the Norfolk Regiment): Acting Surgeon Herbert Francis Prince resigns his appointment.—10th Lanarkshire (Glasgow Highland): George Bell Todd, Gent., M.B., to be Acting Surgeon.

Correspondence.

"Audi alteram partem."

THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—I have been surprised to see how little notice has apparently been taken of the proposed changes for the admission to the Fellowship of the Royal College of Surgeons of England. I allude more particularly to the exemption from the Primary Examination of Members of fifteen years' standing. I trust that, according to the well-known maxim "Audi alteram partem," you will allow me space to enter my protest against this proposed change, although by so doing I show want of agreement with some of the conclusions in your leader in the issue of the 20th inst.

It would be interesting to know on what grounds the Council of the College has felt it to be necessary to increase the number of Fellows on a reduced qualification. At the present time the diploma F.R.C.S. Eng. is considered, and I believe rightly so, the "blue ribbon" of surgical diplomas, I may say of the world. Why? Because of the known severity of the examinations, even apart from the number of distinguished men who have held it. Of the actual examinations the Primary is nowadays the severer, requiring much training and study as well as ability to acquire the requisite knowledge of anatomy and physiology. Every vexatious difficulty, so far as the curriculum is concerned, has now been removed, such as the necessity for extra courses of dissections, lectures, or even the waiting till a certain age is reached. Now any Member, as soon as he has been six years acquiring the knowledge of his profession, may, if he has the ability, present himself for examination and pass. "Where there is a will, there is a way." I know several gentlemen who, whilst engaged in large general practices, by the exercise of the necessary self-denial, have *made* time, read up, and passed the Primary as well as the Final. There is such a frightful tendency at present to level *down*. For goodness' sake, let some diplomas remain which are really distinctions, and which demand serious hard work as well as ability. I doubt whether there be any necessity, or it be even desirable, either in the interest of the College or of surgery generally, to increase the number of Fellows by lowering the present standing of a severe, searching, and scientific examination. There is no falling off in the number of candidates willing and able to undergo the test under the present system. On the contrary, year by year they are steadily increasing. Exactly the same argument might be used in the case of M.D. or M.B Lond., or indeed of any good medical degree, for the exemption to senior men of "subjects of minor importance to the practitioner." Why should not the First M.B., the Preliminary Scientific, or even the Matriculation be dispensed with? I believe the College made a retrograde movement some years ago in abolishing Greek and other extra subjects in the Preliminary Examination for the Fellowship.

I take no exception to the proposal to confer the honorary Fellowship on certain men of standing who have specially distinguished themselves, provided that the power is exercised with very great discretion. They will be known as F.R.C.S. (Hon.), and will not be confused with F.R.C.S. (Exam.), which latter will always carry with it the greater distinction.

I cannot but foresee disaster to the prestige of the College, to its Members equally with its Fellows, if so short-sighted a policy as lowering the standard of any of its examinations be carried out.

Your obedient servant,

London, March 29th, 1886. CHARLES GROSS, M.B., B.S.

THE LATE DR. BALY.

To the Editor of THE LANCET.

"——et idem
Indignor, quandoque bonus dormitat Homerus."

SIR,—The words with which I have ventured to cap this letter rose to my lips on Saturday morning, when startled by the new reading of history contained in the first of your "Annotations." You have there stated, in a moment of very unaccustomed forgetfulness, that Dr. Baly was never made Physician to Her Majesty the Queen; whereas that honourable position was really occupied by him for a year and a half.

In the obituary notice given in your issue of Feb. 9th, 1861 (p. 147) occur these words:—"In 1859 a physician was required who might share with Sir James Clark the office of regular attendance on the Queen and Royal Family. Those who were charged to make a just selection for this high office consulted free from all personal regards, from all solicitations and undue influences; they had the whole profession to choose from; and when, to Baly's great surprise, he was selected, the unanimous voice of the whole profession acknowledged that he was the fittest man. How well he justified the opinion was shown by the proofs of confidence which he received from the Queen and the Prince Consort, and by the esteem in which he was held in all the palace."

The Prince Consort, writing to Baron Stockmar on Jan. 29th, 1861, says (see "Life of Prince Consort," by Sir T. Martin, vol. v., p. 288): "We had the great misfortune yesterday to lose Dr. Baly, who was killed in an accident on the railway between London and Wimbledon. For us this is a serious loss, as he had gained our entire confidence, and was an excellent man, and Clark has quite given up practice."

I may here with propriety add that substantial proof of the Queen's gratitude and esteem followed, not long after Dr. Baly's death, in the assignment to his younger and unmarried sister of a set of apartments at Hampton Court Palace, which she still enjoys.

I am, Sir, yours faithfully,

March, 1886. ONE OF DR. BALY'S EXECUTORS.

*** Our correspondent will, we think, acknowledge, on reflection, that we correctly stated the facts. It is perfectly true that in April, 1859, the Queen was "pleased to appoint Doctor William Baly, F.R.S., to be Physician Extraordinary to Her Majesty," and we regret that we omitted to mention this. The "coveted post" to which we alluded was, however, that of *Physician in Ordinary* to the Queen. We are well aware of the high appreciation in which Dr. Baly was held by the Queen and the Royal Family, and that he went abroad with Her Majesty and attended her in the absence of Sir James Clark.—ED. L.

THE USE OF ANÆSTHETICS.

To the Editor of THE LANCET.

SIR,—In the annotations in this week's LANCET attention is drawn to the dangers which attend the use of chloroform when employed *alone*.

Having had an extended experience in the very frequent administration of chloroform alone, I would venture to think that the very strong opinion publicly expressed against chloroform in THE LANCET is likely to do serious harm, by creating a panic and raising fears and doubts which are not altogether justifiable. If we possessed an anæsthetic agent that was absolutely safe, the cry against chloroform would assuredly be right; but it is not so, and deaths from ether and other agents do occur. Ether may, and

Digitized by Google

does, produce at times alarming and even fatal symptoms. I have seen sudden syncope occur during the administration of ether with Clover's smaller apparatus, and active measures called for to recover the patient. I am convinced that in some cases of strangulated hernia (not necessarily in elderly people) a fatal termination has been hastened by the administration of ether; and though ether rarely kills suddenly, it assuredly does so in some cases—it may be a few hours, or even days, after its administration.

As regards chloroform especially, ought it not, perhaps, to be more fully recognised than it is at present that its administration in surgical operating practice requires a very special study and experience? And, perhaps, it is not justifiable to recommend to a patient that anyone is competent to give chloroform. To enforce the truth of this it is only necessary to refer to the diverse ways in which chloroform is administered. In many cases the attention of the administrator is, unconsciously perhaps, divided between the chloroform and the operation.

In the hands of one who is careful at every moment to watch the respiration of his patient and to ignore the operation, and who gives enough and no more chloroform to produce a quiet unconsciousness, and who avoids pushing it to the degree of stertor, and who also does not neglect the position of the lower jaw and the state of the pulse, chloroform is a comparatively safe and most reliable anæsthetic. The operating surgeon, or his assistant, should assist in its careful administration by avoiding sudden alterations in the position of the patient. It is not justifiable to give chloroform in the sitting or, as I believe, in the semi-recumbent position, and perhaps chloroform should be abolished in dental practice. A subcutaneous injection of one-sixtieth of a grain of atropia with one-twelfth of a grain of morphia should be given about ten minutes before commencing the administration of chloroform. Considering the enormous benefits conferred by chloroform, I would say that, in my humble opinion, what is wanted is not so much a safe anæsthetic as a safe anæsthetist, and to urge that in the hands of those experienced in its use chloroform possesses many advantages both to the patient and the administrator that ether does not. In conclusion, Sir, I write of chloroform as I have found it, and in all humbleness and lowness of spirit, and with no desire to stir up the wrath of the champions of ether *v.* chloroform.

I am, Sir, your obedient servant,

ARTHUR G. BLOMFIELD, M.D.,
House-Surgeon, Devon and Exeter Hospital.

March 27th, 1886.

*** Dr. Blomfield does not make any reference to the A.C.E., the mixture of the three agents, which forms a safe anæsthetic, and by the use of which the dangers of chloroform alone and the inconveniences of ether are avoided.—ED. L.

THE DUBLIN HOSPITALS COMMISSION.

To the Editor of THE LANCET.

SIR,—Your Dublin correspondent has quoted extensively from the evidence given by Dr. Thomson before the Hospitals Commission, and as he seems to agree with him that Dublin is over-hospitalled, and that some of the existing hospitals should be amalgamated, to the advantage of teaching and of the public as well as of the patients, it is right that the other side of the question and reasons for the opposite opinion should be given.

1. Amalgamation is impracticable because the distances are too great to render one auxiliary or ancillary to the other for administration, treatment, or teaching. Moreover, the assurance of a friendly and harmonious co-operation of different staffs would be impossible. 2. The proportion of 6*s.* 8*d.* in the £ to the food of patients and 13*s.* 4*d.* to the general establishment is not worse than the Poor-law system, and it is ordinarily the proportion of necessaries to general house expenses in private families. 3. Dublin is not over-hospitalled, and a comparison with any other city does not afford ground for argument, because Dublin contains a general labouring class (according to the health officer, Sir Charles Cameron, and the Registrar-General, Dr. Grimshaw, not one of whom was examined before the Commission) of about 160,000 or 33,000 families residing in 48,000 rooms with utterly inadequate cubic space, and with a mortality of 42 per 1000 per annum. Such being the case, there will at least be 6 per cent. of this class constantly sick, or 9600; and if we allow that one-half will be able to provide themselves through dispensaries, we have left another to provide for, and at present there are about 2000 in the union hospitals, and there is bed accommodation space in all the hospitals for about 2400; so that Dublin, under its condition, cannot be shown to be over-hospitalled. Each of the staff has only a few patients on account of want of funds. 4. When medical fees are reduced, houses for the poor equal, and the provident system extended in Dublin as in other large towns in the empire, it will be over-hospitalled. 5. It is reasonable that the Imperial grant of £16,000 a year, originally given for encouraging medical research and teaching, as well as for support of hospitals, should be divided into a portion for medical research open to all medical men in the country and into a portion for results. I have clearly and incontrovertibly proved that during twenty-one years at the Army Medical Examinations the Dublin Medical School has lagged in the rear. My proposition, I think, would restore it to its lost position. 6. The public grant should not be shared with specialist hospitals. The reason is obvious. They will always have their special patrons, and the teaching in them, being rather athletic than developmental, does not require national support. 7. The Commission was scarcely well chosen, and the witnesses should have included Sir Charles Cameron and Dr. Grimshaw, the health officer and Registrar-General respectively.

I have the honour to be, Sir, yours faithfully,

JOHN ROCHE, M.D., &c.

Mount Clarence, Kingstown, March 22nd, 1886.

WELLINGTON COLLEGE.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to an occasional note in THE LANCET of March 20th, which speaks of the "number of boys at present excluded from classes through illness" in this school. As such statements, apparently circumstantial, and given with authority, though not derived from nor verified at any official source, are likely to alarm parents and to do wrong to the school, will you allow me to say that the average number of boys out of school on the ground of ailment or accident, grave or slight, during the present term has been 13·6 out of a total number of 405. Unless I am much misinformed, this is not a large average as compared with other healthy schools in such an exceptionally severe spring. As soon as the weather mitigated, the number dropped to the usual average. The maladies have been mainly slight colds and coughs. There have been two cases of pneumonia, both of them now convalescent. Perhaps I may also say that the daily average of boys out of school during the past year was under 4, during the past two years under 4·5, out of rather more than 400. In the two years there have been only two cases of infectious illness, one of measles and one of scarlatina.

I am, Sir, your obedient servant,

E. C. WICKHAM,
Head Master.

Wellington College, Wokingham, March 23rd, 1886.

*** Mr. Wickham does not mention that during the period embraced by his letter, in which the institution is represented to have been exceptionally free from illness, one of the masters of the College died from septicæmia after six days' illness, that a boy died from peritonitis after four days' illness, that one of his own household died also of peritonitis, that a servant of the College died from pneumonia after four days' illness, and that a labourer on the grounds died also of pneumonia complicated by septicæmia. These following other similar deaths are suggestive of insanitation. From 13 to 14 per cent. of the deaths in the registration area in which Wellington College is situated are caused by pneumonia. These facts point to a distinct pneumonic tendency in the locality. The two boys recently ill with pneumonia, out of an average of from thirteen to fourteen cases of sickness, is a further confirmation of this disposition to pneumonia in the district. At the schoolboy age pneumonia is rare, for it is a disease affecting chiefly those under five and over twenty. Moreover, an average of from thirteen

Digitized by Google

to fourteen boys incapacitated for work through illness at any one time, and in the absence of infectious disease, is more than should occur among healthy schoolboys. If Mr. Wickham will compare this number with the number of boys detained at home through illness after the Christmas vacation, when they have been subjected to all the irregularities and festivities of Christmas holiday time, during the coldest month of the year, we think he will find that the illness among the boys while under his charge, "in loco parentis," is in excess of what occurs while under their own parents' supervision. This should not be the case. We hope the time is not far distant when every public school will be called upon to make an annual return of sickness. At present there are no trustworthy statistics available.—ED. L.

HOPEINE.

To the Editor of THE LANCET.

SIR,—Referring to a letter of "Seismos" in THE LANCET, p. 497, regarding the composition of hopeine, I beg to call your attention to the explanation published by Dr. Williamson in the *Chemiker Zeitung* (1886, p. 238). According to this statement, the wild Arizona hops, as well as the lupuline obtained therefrom, contain at least two alkaloids—viz., one similar and probably even identical with morphia, called isomorphia, the other different from morphia in its physical and chemical properties as well as in its physiological action. The fact, proved by further experiments conducted by Dr. Williamson, that the precipitated hopeine prepared by an English manufacturing firm and supplied to French physiologists contained two alkaloids (both extracted from lupuline) has been confirmed by an analysis by Mr. Harland and independently by Dr. Weissenfeld. The quantity of isomorphia, according to Dr. Weissenfeld's statement, is larger in the lupuline than in the hops, while in hops separated from lupuline the other alkaloid (hopeine) is contained in larger propdrtion. As the quantity of alkaloids contained in hops is exceedingly small, the experiments meet with unusual difficulties. It seems that even Dr. Williamson's pure hopeine contained traces of isomorphia, and the principal object of further experiments is the separation of the two alkaloids after extracting the same from hops or lupuline. There can be no doubt that hopeine greatly differs from morphia and from isomorphia. A small sample I received from Dr. Williamson (although producing the well-known morphia reactions arising probably from traces of isomorphia) had a very marked mydriatic influence on the pupil of the eye, while morphia never produces dilatation. The pungent bitter flavour of pure hopeine and the burning effect on the nerves of the tongue are followed by insensibility of the same to a certain degree. Concentrated solutions endermically applied produce a prickly sensation on the skin. The effect on the system, if used hypodermically, is exceedingly strong, and hopeine could not be injected without danger in the same dose as morphia; dogs are killed by half the dose of hopeine than that required of morphia.

I am, Sir, yours faithfully,

Camomile-street, March 12th, 1886. W. WILD, M.D.

DEGREES FOR LONDON MEDICAL STUDENTS.

To the Editor of THE LANCET.

SIR,—"Post factum nullum consilium" is indeed most true, and will be bitterly proved to many a man now labouring to get the London Colleges' licence to practise, unless our Colleges have the pluck, they certainly have the success, to obtain power to grant degrees instead of that, to the general public, unknown quantity called a "licence." I speak from experience on this subject, and none know where the shoe pinches so well as he who wears it.

A short time since I succeeded to a good-class practice in a residential suburb of a large provincial town. My professional brethren are mostly old-established M.D.'s, and to my certain knowledge, having been told by mutual friends, I have lost several families simply because they would have a "Doctor," and not a mere "Surgeon"; besides this, I am constantly reminded, of course indirectly and most politely, that a surgeon is a very second-rate man compared to an M.D. A few days ago a sort of deputation of relatives and friends called upon me to urge my taking a degree, for, being anxious for my success, they saw, they said, how much the want of a degree handicapped me. This, Sir, is outside testimony, and therefore of value. Of course I have now no time or opportunity to take a degree, and consequently must go on living down public opinion that our English qualifications are as naught compared to an M.D. until our Colleges assert our rights.

No time could be more opportune than the present for our Colleges to get the Charter they are entitled to. Her Majesty has conferred a great honour upon them and us; would she not be equally willing—nay, anxious—to do us justice as well as honour? I am, Sir, yours truly,

March, 1886. JUSTICE.

CYCLICAL ALBUMINURIA.

To the Editor of THE LANCET.

SIR,—I am sorry that I did not notice Dr. Pavy's acknowledgment of my paper, and am obliged to him for his letter. My experiments were something more than repetitions of those in his Gulstonian lectures, and arrived at different results. My table was not intended to show the albumen per hour. The periods are too long, and the results, when used for this purpose, obviously misleading. Runeberg (zur Frage des Vorkommens der Albuminurie bei gesunden Menschen) is the only writer I know who has given a table of the hourly secretion of albumen, and that fully bears out my argument, as it shows that the albumen in the forenoon is not only relatively, but absolutely greater per hour.

I am, Sir, yours obediently,

Birmingham, March 31st, 1886. ROBERT SAUNDBY, M.D.

EDINBURGH.

(*From our own Correspondent.*)

END OF THE WINTER SESSION.

THE winter courses of lectures in the Medical Faculty of the University came to an end on March 31st, the customary valedictory addresses being delivered and the results of the class competitions announced. In the Extra-academical School the session was brought to a close on the 26th inst.

SCHOOL OF MEDICINE, SURGEON'S HALL.

At a recent meeting of the lecturers to the Royal College of Surgeons, Dr. D. Berry Hart was elected to the Lectureship of Midwifery and Diseases of Women, in the room of the late Dr. Angus Macdonald. Dr. Hart has already acquired the reputation of a successful extra-academical lecturer upon these subjects, having delivered courses of lectures during two summer sessions, which have been well attended by students, and he will prove a most valuable addition to the teaching staff of the College.

HONORARY DEGREES OF EDINBURGH UNIVERSITY.

A list of honorary degrees to be conferred at the approaching graduation ceremonial has been published. Amongst those who are to receive the degree of LL.D. are Professor Dicey, Fellow of All Souls College, Oxford; Mr. R. M. Cust, Secretary of the Royal Asiatic Society; Dr. F. J. Mouat; Sir Chas. Nicholson, Bart., M.D., formerly Chancellor of the University of Sydney; Mr. John Small, M.A., Librarian to the University of Edinburgh; Dr. Schmitz, formerly Rector of Edinburgh High School; and Mr. John Wilson, Emeritus Professor of Agriculture in the University of Edinburgh, and until recently Secretary to the Senatus Academicus.

UNIVERSITY REFORM.

The members of the University General Council Association are again taking active steps in the direction of urging upon Government the necessity for a sweeping measure of reform. A memorial upon the subject, signed by Dr. Rutherford Haldane, chairman of the General Committee of the Association, has been forwarded to the Secretary for Scotland. The memorial, which is a carefully compiled document of considerable length, contains a number of recommendations, the substance of which, it is hoped, will be introduced into the Universities (Scotland) Bill, when that long-expected measure does at length make its appearance. These recommendations deal specially with the relative status and powers

Digitized by Google

of the University Court, the Senatus, and the General Council, In the first place, it is urged that the General Council, a body composed of 5000 members, graduates of the University, should have some distinct representation in the management of University affairs. To secure this, it is proposed to aggrandise the University Court by giving it the entire control of University finance, which is at present administered by the Senatus, by increasing its membership, at the same time making it a public Court, and by making it truly representative of all University interests, the proposition being that of the fifteen members of the proposed Supreme Court no fewer than five shall be elected by the General Council, whilst the Senatus shall have two representatives and the matriculated students one; the Town Council and certain educational bodies to be represented also by assessors. Another of the recommendations deals with extramural or open teaching; it is strongly urged that this principle should be extended to all the faculties in the University, the great success which has attended its application to medicine, in the development of the Edinburgh School, being cited as an instance of what might result in other branches of technical education were the system more extensively brought into vogue. The memorial is a document of considerable importance, since it represents the view very generally held by members of the Extra-academical School, and by many who are even more closely connected with the University.

PROPOSED STUDENTS' UNION.

A great effort is at present being made in Edinburgh by the students and their friends to found a Union and Debating Club on the plan of the institutions which bear the same name at Oxford and Cambridge. The scheme includes the erection of club buildings, which are to contain a fine hall for union debates, dining, smoking, and reading rooms, committee rooms, &c. It is hoped that an institution of this character will, to some extent at least, obviate the great defect in the Scottish university system—viz., the all but complete isolation in which the students individually live, and as a result of which they lose that social interchange of ideas which is so important a part in the broadening influences of an academic career. The scheme has received already considerable material support from past graduates of the University, and it is hoped that many more will contribute towards this valuable addition to the educative effectiveness of their *alma mater*. Contributions in furtherance of the scheme should be sent to the secretaries of the Students' Representative Council, at the University.

Edinburgh, March 31st.

IRELAND.

(From our own Correspondent.)

SACCHARIN.

SACCHARIN is a substance lately discovered in America by Professor Falberg, which is 230 times sweeter than sugar, and is obtained from coal-tar. At a recent meeting of the Royal Dublin Society Professor Emerson Reynolds, F.R.S., read a paper on this substance, which is of importance to medical practitioners, inasmuch as it can be used to sweeten and render palatable the food of persons who, suffering from diabetes, are precluded from using sugar, and for some months past it has been used for this purpose in one of the Berlin Hospitals. In appearance it resembles flour, but it is denser and is dissolved easily by hot water. It is rather an expensive substance, its present price being about 40*s.* per pound. The reason of the high cost of saccharin is due to the complex nature of the operations in obtaining it from coal-tar. As, however, an ounce of it will go as far as fourteen pounds of sugar, its actual expense as a sweetening agent is not much greater than that of sugar. Professor Reynolds referred in his paper to the question as to whether this substance could be taken without detriment to the human frame. To ascertain this, experiments were made on dogs, and eighty grains were administered daily to a dog for some time, without the slightest ill effects. When the cost of production becomes lessened saccharin may become a formidable rival to the sugar manufacture.

LEFT LUMBAR COLOTOMY.

I had an opportunity last Tuesday of seeing, at the City of Dublin Hospital, some cases of lumbar colotomy, recently operated on by Mr. H. Gray Croly, senior surgeon to that institution. The cases were three in number: two males, operated on for scirrhus of the rectum eight days and six weeks since respectively; and a female a fortnight ago, for recto-vaginal fistula. The cases are all going on favourably. It is rather an unusual circumstance that there should be three cases of lumbar colotomy in hospital at one time, and operated on by the same surgeon, and it is therefore worth recording. In the same hospital there is another patient, who, singular to state, has for the second time had Cock's operation for impermeable stricture performed on him by Mr. Croly—a most unusual occurrence.

SCLERODERMA.

An example of this very rare disease was exhibited last week at a meeting of the Medical Section af the Academy of Medicine in Ireland, by Dr. George F. Duffey. The subject was a female, and the disease commenced in February, 1885, on the index and middle fingers of the right hand, and in the following October both hands became implicated. At present there is a good deal of rigidity of both forearms, with some swelling of the hands, while the side of the neck and front of the chest are also implicated. The treatment adopted by Dr. Duffey was the internal administration of the iodide of potassium, and the local application of glycerine of starch, and from all accounts an improvement in the parts affected has certainly taken place.

THE DUBLIN BARRACKS.

It is stated that in consequence of the condition of the barracks in Dublin it is contemplated, in addition to the block of new buildings which are to be built at a cost of £112,000, to expend a sum of £1750 on the drainage of the Richmond Barracks.

Dr. Thomas Leary, of Castlederg, has been placed on the Commission of the Peace for the County of Tyrone.

Dublin, March, 30th.

BELFAST.

(From our own Correspondent.)

THE ROYAL UNIVERSITY.

A CONTEST is at present going on for a seat in the Senate of the Royal University. Mr. William Thompson of Dublin is a candidate, and will be strongly supported by the northern graduates of all professions. Mr. Thompson is himself a graduate in Arts and in Medicine of the late Queen's University, and is a leading Dublin surgeon, being connected with one of the hospitals. The feeling here is very much in his favour, and his election will give great satisfaction.

THE ROYAL HOSPITAL.

At the ordinary weekly meeting of the Board of Management of the Royal Hospital, held on March 20th, Mr. W. T. B. Lyons, D.L., was presented with two portraits of himself, one for the hospital, the other for his own family, by the members of the Board of Management and Life Governors. Mr. Lyons has for years devoted himself with energy to the work of the Royal Hospital, and, as a speaker at the meeting pointed out, he has been a zealous worker and sound adviser, in the darkest as well as the brightest days of the charity.

BELFAST OPHTHALMIC HOSPITAL.

From the reports presented at the last annual meeting of this deserving charity, we gather that during the past year 1260 cases have been treated in the extern department, 890 for diseases of the eye, 360 for diseases of the ear, and 70 for throat diseases, while in the wards of the hospital 89 cases have received treatment for more severe forms of similar diseases. The recipients of the charity have been chiefly the poor of Belfast and the North of Ireland. During the year the sanitary condition of the hospital has been carefully inquired into, and every effort made to keep the house in an excellent state of sanitation. During the past year a large sum of money has been expended in extensive and much-needed repairs, and in painting and papering the greater part of the house. Lady Johnston, with her usual generosity, on ascertaining this, offered to defray all the expenses therewith, and the accounts, amounting to over £54, have since most generously been paid by her. A large class of students is receiving clinical instruction at the hospital.

Digitized by Google

THE TOWN COUNCIL.

Owing to the death of one of the aldermen there is at present a contest, and Dr. James Graham has been requested to come forward by ratepayers of all shades of political opinion, who deplore the present intolerable nuisance caused by the River Lagan, which is practically an open sewer, and who think that there should be some amendment of the deleterious influence caused by emanations from the gas-works. Dr. Graham, who lives in the vicinity of both these nuisances, pledges himself to endeavour to have the existing state of sanitation remedied. As Dr. Graham is deservedly popular, and as he is coming forward on the public health platform, we are likely to have an interesting contest.

Belfast, March 30th.

PARIS.

(From our own Correspondent.)

REAPPEARANCE OF CHOLERA IN BRITTANY.

INTELLIGENCE has reached Paris of the reappearance of cholera in Brittany. It will be remembered that the disease committed great havoc in the Guilvincc and Audierne, two fishing villages, to which the origin of the present threatened epidemic has been traced, and where, it is suggested, the germs of the disease have lain dormant till now. The reappearance of the disease is attributed, as usual, to overcrowding and to the filthy condition of these places, particularly at this time of the year, when there is a great influx of fishermen from different parts of the littoral of Brittany. Within the last fortnight about 2000 have already arrived, who, finding it difficult to get lodgings, huddle themselves together in every available hut, where they take their families, nets, and other instruments used in fishing, without even washing them or themselves before retiring. Notwithstanding the severe lesson of last year, nothing seems to have been done to avert the possible return of another epidemic of cholera. It is reported that on the 23rd inst. a fisherman arrived at Tréboul from Audierne, where it was known that he was affected with cholera. He was soon followed by others equally affected by the disease, and to the 29th of March, after a few deaths, the exact number of which was not given, there were in the small village of Tréboul thirty cholera patients, one-third of whom are said to be in a very serious state. It would appear that this locality is not the only one infected, as two fatal cases were reported to have occurred at Gouesnou, about six kilometres from Brest, and several cases have occurred at Concarneau, where one death took place on the 26th. There cannot be two opinions as to the culpable neglect on the part of the authorities in having allowed these men, who were known to have been affected with cholera, to travel about the country and thus propagate the seeds of the disease.

DEATH OF DR. FOURNIÉ.

Dr. Edward Fournié, a well-known laryngologist, died on the 24th inst. in the fifty-fourth year of his age. He began his career as an officier de santé in the navy during the Crimean War. After the war he took his degree at Montpelier, then proceeded to Paris and devoted himself to scientific researches, particularly on the functions of the different parts of the encephalon and of the nervous system. He published several works appertaining to the brain and throat, and was for many years Medical Director of the National Institution for the Deaf and Dumb. He was also editor of the *Revue Médicale Française et Étrangère*.

Dr. Gallard has been elected member of the Academy of Medicine; and Professor Vulpian, Perpetual Secretary to the Academy of Sciences, in the place of M. Jamin (deceased).

Paris, March 31st.

BRISTOL EYE HOSPITAL.—At the annual meeting of the subscribers to this institution on the 29th ult., it was reported that during last year the number of patients under treatment was 11,224, an excess of 709 over the previous year. The receipts amounted to £771, a sum which exceeded the expenditure by £40. The premises at present in use are inadequate, and the committee appeal for funds to enable them to carry out in a satisfactory manner their intention of considerably increasing the accommodation of the hospital.

NEW YORK.

(From our own Correspondent.)

AN HONORARY DEGREE FOR MR. LAWSON TAIT.

AT the annual commencement of the University Medical College on March 6th, the announcement was made by the Chancellor that the University had conferred the honorary degree of Doctor in Medicine upon Mr. Lawson Tait of Birmingham, England. Applause greeted this action of the University, for Mr. Tait has many very enthusiastic admirers in New York. His visit to this city, and especially his operation upon two patients in the great amphitheatre of Bellevue Hospital, was a memorable event. He diagnosed diseased ovaries in each case, after a brief examination in the presence of several hundred medical men and students, and proceeded at once to operate. His diagnosis proved to be correct, and both patients made good recoveries, though antiseptics were not used. He has several followers in New York, and extirpation of the ovary is now of almost daily occurrence. The antiseptic treatment, however, is very rigidly followed.

DEATH OF DR. S. O. VANDERPOEL.

Dr. Vanderpoel was well known for the interest he took in quarantine reforms. He was for many years health officer of this port, and was successful in placing it on a thoroughly practical basis. Detention for a given period was no longer the rule governing the care of ships, but sanitary inspection and cleansing became the practice. The result of this policy was that shipmasters took the utmost pains to bring their vessels into port in the most cleanly condition, and thus they were able to escape quarantine. Dr. Vanderpoel was Professor of Hygiene in the University Medical College. He was a supporter of the new code movement.

DEATH OF DR. AUSTIN FLINT.

While writing the above the announcement was made that this eminent physician had been stricken with cerebral apoplexy, and immediately after followed the news of his death. No physician was better and more favourably known in this country. He had been teacher and author for forty years. His father and grandfather were physicians of considerable eminence, and he early began a course of studies preparatory to entering upon the study of medicine. He first located in the western part of this State, where he established a medical periodical. He began to give courses of lectures in medical colleges, and at one time was connected with a school in New Orleans. Subsequently he located permanently in New York, where his best work was done. He was selected as president of the proposed session of the International Medical Congress at Washington in 1887. Dr. Flint was in his seventy-fourth year, and gave no evidence of failure of health. He was busily preparing for the meeting of the British Medical Association, where he was to deliver an address.

MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

The next meeting of this body will soon occur, at St. Louis. It is anticipated that some decisive action will be taken in regard to the much-disputed meeting of the International Medical Congress. There is no change in the current of medical opinion in regard to the controversy which has arisen. The profession as a body take little interest in the matter, while those engaged actively in the dispute remain hostile and unreconcilable. It is hoped that when the Association meets all differences will be adjusted and harmony secured.

New York, March 14th.

MEDICAL NOTES IN PARLIAMENT.

The Lunacy Acts Amendment Bill.

IN the House of Lords, on the 30th ult., the Lunacy Acts Amendment Bill was considered in Committee on recommitment. The Lord Chancellor proposed amendments, which were agreed to, modifying in some particulars the clauses relating to private asylums. Lord Grimthorpe expressed his opinion that no case whatever had been made out against private asylums, and he quoted figures to show that the discharges from those institutions were more numerous than the discharges from public asylums. The Lord Chancellor did not concur in the conclusions of Lord Grimthorpe,

Digitized by Google

and he pointed out that, untested, the figures relied on by that noble and learned lord were of little value in the argument, because the removals from one private asylum to another were much more frequent than those from one public asylum to another, and no doubt all removals were enumerated under discharges. The various clauses having been agreed to, the Bill was ordered to be reported with amendments.

The Idiots Bill.

The Lord Chancellor moved the second reading of the Idiots Bill, which, he said, was drawn on the same lines as his Lunacy Acts Amendment Bill. The motion was agreed to.

Contagious Diseases Acts Repeal (No 2) Bill.

In the House of Commons, on the 25th ult., Mr. Stansfeld moved the second reading of this Bill. Mr. Cavendish Bentinck strenuously opposed the repeal of the Acts, and gave instances of cases in which their operation had been beneficial. Eventually, when the question was put a first time a division was challenged, but on the second occasion the second reading was agreed to without opposition.

Vaccination.

In reply to Mr. A. O'Connor, who asked the Under Secretary of State for Foreign Affairs if he would obtain information respecting the vaccination with humanised lymph of seventy-nine children in the Island of Rügen in June last; whether it was true that seventy-six of them were attacked in a few days with contagious disorder, which was communicated to their parents, brothers, and sisters to the number of 320; what number of the children died; and whether the lymph was obtained from the Royal Vaccine Institution at Stettin,—Mr. Bryce stated that Her Majesty's Ambassador at Berlin had been instructed to report on the subject.

Obituary.

JOHN FREMLYN STREATFEILD, F.R.C.S.

ON Thursday, March 18th, there somewhat suddenly passed away, at his house in Upper Brook-street, John Fremlyn Streatfeild, the Senior Surgeon of the Moorfields Ophthalmic Hospital, Ophthalmic Surgeon to University College Hospital, and Professor of Clinical Ophthalmic Surgery in University College. His illness was a short one. He performed an iridectomy for glaucoma on the previous Friday, and saw some patients at his own house on Saturday morning, but he felt too ill to go out, and sought the aid of his friend, Dr. J. E. Pollock, whose unremitting care was unable to arrest the progress of an acute attack of pneumonia, which terminated in death at a few minutes before two on Thursday afternoon. Mr. Streatfeild had had several attacks of bronchitis, and a few weeks before his fatal illness had a threatening of pneumonia, which apparently passed away after a few days' rest in bed. In unselfish obedience to a professional call he took a railway journey into Kent on one of the last days of the prolonged severe weather, and received a chill, to the effects of which he succumbed.

John Fremlyn Streatfeild was the son of the well-known Kent antiquarian, the Rev. Thomas Streatfeild, of Chart's Edge, Westerham, Kent, by his second wife, Clare, the daughter of the Rev. Thomas Harvey, of Cowden, and was born on October 14th, 1828. His mother is still living, and in her ninety-third year. He was a delicate boy, and until the middle of his fifteenth year was educated at home by his father. He then went to the King's School at Canterbury, and afterwards for a short time to a school at Tunbridge Wells. He commenced his medical education as the private pupil of Mr. Curling, and entered as a student at the London Hospital. He became a Member of the Royal College of Surgeons in the year 1852, and during the Crimean War served, with many others known to fame, on the surgical staff of the British Civil Hospital at Smyrna. On his return to London he entered upon the study of ophthalmology, and was soon afterwards elected assistant surgeon to the Royal London Ophthalmic Hospital. In 1862 he obtained the Fellowship of the College of Surgeons. He had previously been appointed assistant ophthalmic surgeon, and soon after ophthalmic surgeon, to University College Hospital as the coadjutor of Professor Wharton Jones. He was temporarily compelled to resign this post, as a new rule had been adopted at Moorfields disqualifying for promotion at that hospital anyone who held another ophthalmic appointment. The rule was found to be inconvenient, and was speedily repealed, when Streatfeild was at once re-elected at University College Hospital.

Professionally Streatfeild will be best remembered for his great dexterity in the performance of purely ophthalmic operations. His facility in making his corneal sections was remarkable, and his skill gained for him a considerable reputation. A certain brusqueness of manner, however, militated against his obtaining a large practice, as sometimes to strangers it made him appear unsympathetic. Streatfeild required to be known to be appreciated; he was certainly not unsympathetic. Associated with his characteristic bluntness there was just beneath the surface a vein of fun ever ready to show itself, and with it no slight admixture of wit and humour. Deeper still there was a genuine sincerity, a large-heartedness, and a courageous conscientiousness which gained for him a wide respect and esteem. His circle of intimate friends was not large, as he was of somewhat retiring habits and little cared to show himself at the meetings of the Medical Societies. He was a staunch Churchman and religiously gave away a tenth of his income. He inherited his father's antiquarian and archæological tastes, and was a collector of Wedgwood, of books, of antique furniture, and especially of anything belonging to or illustrating the history of his native county of Kent, of which he had a great love. No mean draughtsman himself, he had collected a large number of drawings and sketches of much that is quaint and picturesque in Kent, of its churches, its gables and chimneys, many of which were done by his own hand during the holidays that he loved to spend with his family in what was to him truly the "Garden of England." With the sketches he brought together during these visits a large number of facts, historical and otherwise, bearing upon the history of Kent and upon its manners and customs, which he intended, if he had lived, to have made into a book. No doubt the Kent Archæological Society, of which he was an active member, will take care that all this interesting material is not lost.

Streatfeild was a frequent contributor to the literature of his specialty. For a short time he edited the London Ophthalmic Hospital Reports, and often have its pages contained notes of his cases and illustrations by his pencil. He wrote the chapters on Ophthalmology in Erichsen's great Text-book of Surgery, and papers and "notelets" have appeared in the columns of THE LANCET. More lately, he contributed several special articles to Quain's Dictionary of Medicine. His literary style of composition was peculiar, and to many readers it sometimes failed to convey clearly the meaning intended; but his writings always showed both originality and practical experience. He was one of the founders of the Ophthalmological Society of Great Britain, and its treasurer from its formation. Few of its Fellows who were present will forget the humour with which he recently demonstrated with huge dummy instruments the steps of the operation of extraction of cataract, as a suggested means of teaching to a class the manipulations of ophthalmic surgery.

Mr. Streatfeild was in his fortieth year when he married, and leaves a widow and three children.

O. E. P. CHARD, M.B. LOND., M.R.C.S., L.S.A.

GRIM death has of late been busy in our ranks. Among the members of our profession who have lately passed away might be enumerated many who have been more celebrated for their writings, or more widely known to the public at large, but none who will be more missed in private life, more lamented among his friends and patients, than the subject of this notice. Mr. Chard passed his examinations at the College and Hall in 1846. He commenced practice at Eccleston-street, Pimlico, in 1851, and while busily occupied in attending to an ever-increasing number of patients, found time to graduate and obtain the degree of Bachelor of Medicine at the University of London in 1861. His medical friends and neighbours had frequent opportunities of observing the zeal, the kindness, the solicitude, and—to his

Digitized by Google

poorer patients especially—the benevolence of the deceased. His charity to the really deserving was equalled only by the unostentatious manner in which it was bestowed. A harder worker never lived, and but for the cares of general practice, his education, penetrating intellect, and practical ability, would have secured for him a world-wide reputation. It was to his marked character of kindness to patients and abnegation of self that he owed his rapidly fatal illness in the sixty-second year of his age. On the 3rd inst. he was called to a patient suffering from severe pneumonia. In his anxiety to save a life, he spent many hours of the subsequent five days and nights by the patient's bedside. On the 8th inst. he broke down under this severe strain of his nervous system, took a severe cold ("a chill"), showed symptoms of peritonitis, and in spite of the anxious efforts of his medical attendants, succumbed to the attack on the 13th inst. Truly may it be said that, "He was skilful enough to have lived still if knowledge could be set against mortality."

Medical News.

UNIVERSITY OF CAMBRIDGE. — At a congregation held on March 25th the degree of Bachelor of Medicine was conferred on the following gentlemen:—

Walter Edwin Facey, St. John's; Herbert Paget Tayler, Clare; Walter Hamilton Hylton Jessop, and William Thomas Holmes Spicer, Gonville and Caius.

At Gonville and Caius College, the Shuttleworth Scholarship of the value of £60 for proficiency in Botany and Comparative Anatomy, open to the competition of all registered medical students of the University who are of not less than eight terms' standing, has been awarded to John Sydney Edkins, scholar of the College.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Court of Examiners held on the 22nd ult. and following days, the following passed the first half of the examination for the Letters Testimonial of the College:—

Joseph Daly, Joseph C. Lavertine, Ronald McDougall, John J. Myles, and Edmond F. B. Russell.

Twelve candidates were rejected.

At examinations recently held at the Medical School of the College, medals in Surgery were awarded as follows:—

Edwin Tyrrell Cummings, Senior Silver Medal.
Cecil L. Strangman, Junior Silver Medal.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on March 25th:—

Avarne, Arthur Blair, King Henry's-road, Regent's-park.
Aston, William, Ivy House, Codsall, Wolverhampton.
Harney, Thomas Richard Aloysius, M.R.C.S., Australia.
Sealy, Francis Marmaduke, Gosberton Vicarage, Spalding.

COLONIAL AND INDIAN EXHIBITION.—Her Majesty the Queen has intimated her intention of opening the Colonial and Indian Exhibition on Tuesday, May 4th.

AT the recent meeting of the governors of the Suffolk General Hospital, Dr. Macnab, of Bury St. Edmunds, was elected a vice-president of the institution.

VACCINATION GRANT.—Mr. Philip E. Hill, of the Crickhowell Union, has received for the fifth time the Government grant for efficient vaccination.

THE Royal Belgian Society of Medical and Natural Sciences has awarded a gold medal to Dr. Courtin of Bordeaux, for his treatise on the Treatment of Stricture of the Œsophagus.

LEGACIES FOR PRIZES.—M. Jeunesse has left the Faculty of Medicine of Paris sums of 1500 francs and 750 francs for the foundation of prizes in Hygiene and Histology respectively.

HOSPITAL FOR EPILEPSY AND PARALYSIS.—At the nineteenth annual meeting of the governors of and subscribers to this institution, on the 31st ult., it was stated that the total income for the past year amounted to £1908, and the debt by which the charity is hampered now amounts to £1400. The number of in-patients during 1885 amounted to 106, and the attendances of out-patients were 8088.

YELLOW FEVER AT PORT ROYAL.—The latest communications from Jamaica report that the Duke of Sutherland's yacht, *Sans Peur*, has been placed under quarantine at Port Royal, yellow fever having been contracted on board at Colon. There were four cases, one being rather serious.

AT an inquest held on the 31st ult., touching the death of Alfred H. Hackney, M.R.C.S., L.S.A., who died on the 28th ult., after inhaling chloroform for the relief of neuralgia, the jury returned a verdict of "Death from misadventure."

THE Baroness Burdett-Coutts, Lady Wolseley, and others, have started "scrap" carts, which collect broken food in Belgravia and Mayfair. It is carefully cooked and made into soups, stews, pies, and puddings, and sold at a penny a dish to the poor.

HASTINGS AND ST. LEONARDS SANITARY AID ASSOCIATION.—The fifteenth annual meeting of the members and friends of this Association was held on the 30th ult. It is claimed for this Society that it is the parent of similar institutions in London and elsewhere.

OPHTHALMOLOGICAL SOCIETY.—In consideration of the ordinary meeting of this Society on May 6th being arranged to be devoted to the discussion of the subject of Exophthalmic Goitre, it has been decided to hold an extra meeting, which has been fixed for the 8th inst.

FOTHERGILLIAN GOLD MEDAL.—This medal has been awarded by the Medical Society (trustee of the fund) to John Strahan, M.D., of Belfast. The successful essay is entitled "The Nature and Varieties of the Fevers prevalent in the United Kingdom," and will be published in due course in the Society's Transactions.

THE long-disused Spa Fields burying-ground to the south of Exmouth-street, Clerkenwell, being about to fall back to the freeholder, the Marquess of Northampton, has been handed over to the Playground Society, which is now enabled, in consequence of a grant from the Lord Mayor's fund, to employ a number of men in draining and levelling it.

"THE MAID OF KENT."—A maiden lady, named Heathorn, who is known by this title, has just completed her 103rd year, having been baptised at Maidstone in April, 1783. The venerable lady possesses all her faculties, and is reported to have endorsed a cheque without the aid of glasses on her birthday, which occurred last month.

A CLERK, until recently employed in the office of the General Council of Medical Education and Registration, in Oxford-street, has been sentenced to four months' imprisonment for embezzling sums of money, believed to amount to upwards of £500, which had been paid to him as fees for certificates of registration.

DR. EDWARD BRONNER, a German physician, who has spent some thirty years of his life in England, died a few days since at Bradford, Yorkshire. Dr. Bronner was an ardent politician, and in 1849 sat as a representative of the people in the Constituent Assembly of Baden. He was also remarkable for wide benevolence amongst the poor. He translated into English Moleschott's "Chemistry of Food."

SMALL-POX AT TOTNES.—An outbreak of small-pox at Totnes, and the efforts of the sanitary authority to check the spread of the epidemic by means of disinfection, seem to have caused considerable excitement in the town. The opposition to the precautionary measures has, it is reported, even assumed the form of personal violence against the medical officer of health and the nuisance inspector.

EAST RIDING COUNTY ASYLUM, BEVERLEY.—On the 26th ult., at about 5.20 P.M., an outbreak of fire took place in the above asylum. The fire was first observed in the roof of the house occupied by Dr. Macleod, the medical superintendent, and was well alight before being discovered. There was a strong wind blowing, which caused the flames to spread rapidly. The asylum engine and brigade were very promptly got into use. It was at once seen that the portion on fire could not be saved, so the efforts of the brigade were directed to preventing the fire spreading to the female wards, to which the superintendent's house is attached. In these efforts, aided by the direction of the wind, they succeeded. Other engines were on the spot in due time, and the fire was extinguished. The discipline of the asylum was

Digitized by Google

excellent; the patients were out of all harm's way without any panic or uneasiness, and, had matters turned out worse, no difficulty would have occurred in removing them to some place of safety. No one was hurt or in any way injured. Much property was saved, but Dr. and Mrs. Macleod lost their wardrobes, &c.

ST. JOHN AMBULANCE ASSOCIATION.—The half-yearly report of the North Yorkshire and Cleveland Miners' Association, just issued, makes very gratifying reference to the advantages of the instruction afforded by the St. John Ambulance Association. It is stated that classes have now been established at nearly every mine, and over 1800 men have become thoroughly qualified to render first aid in case of accident.

ACTION FOR ALLEGED CARELESS ADMINISTRATION OF CHLOROFORM.—An action at law has been instituted against two of the most renowned surgeons in Russia, Professor Sklifasofski and Dr. Kusmin, for alleged carelessness in administering chloroform, causing the death of the patient. It is reported, however, by the *Moscow List* that the necropsy proved that the cause of death was not narcosis, but something else.

LONDON HOSPITAL.—Last week a highly successful ball in aid of the funds of this hospital was held, and it is expected by the promoters of the gathering that, after paying all expenses, a goodly sum, measured by hundreds rather than by scores of guineas, will be available to hand over to the treasurer of the institution. During last year the total number of in-patients admitted was 8106, of whom 5754 were free, the rest being recommended by governors. The out-patients treated in that period were 67,942. To meet its expenses, the institution has an assured income of about £14,300, while, notwithstanding the utmost economy, its expenditure cannot be kept below £47,000.

UNIVERSITY COLLEGE HOSPITAL.—The annual general meeting of the governors of this institution was held on the 26th ult., when the report of the Council for the past year was received. It was stated that, though the total annual subscriptions had not fallen off, the legacies had decreased by £4000. Instead of a festival dinner, it is intended this year to hold a bazaar and fancy dress ball. The number of in-patients during the year was 2860. It is to be regretted that at the end of the year the hospital was in debt to the tradesmen and bankers to the amount of £13,652—an excess of £2556 over the deficit of the previous year.

THE HOMES OF THE WINDSOR POOR.—An important meeting was held at the Windsor Guildhall on the 25th ult., for the purpose of considering a scheme for the improvement of Bier-lane, one of the poorest quarters of the Royal borough. After a full discussion of the subject the meeting was adjourned for a month, in order that the Town Council may take such steps as they deem fit in furtherance of the project. The co-operation of several of the Royal Princes as patrons of the undertaking has been secured, and it is proposed to establish a limited liability company, to be called "The Windsor Artisans and Labourers' Dwellings Improvement Company."

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BELL, CHARLES E., M.B.O.S., L.R.C.P., has been appointed Surgeon to the Devon and Exeter Hospital, Exeter, vice William Budd, resigned.

CLIFTON, CHARLTON, M.B., C.M.Edin., has been appointed Ambulance Surgeon to the Northern Hospital, Liverpool.

DOWNES, HOWARD, M.R.C.S., L.R.C.P.Lond., has been appointed Registrar and Resident Clinical Assistant to the North-Eastern Hospital for Children.

EDGELOW, PERCY, M.R.C.S., L.R.C.P.Ed., has been appointed House-Surgeon to St. Peter's Hospital.

EVANS, THOMAS MELANCTHON, M.R.C.S., L.S.A.Lond., late Senior Assistant Surgeon, has been appointed Surgeon to the Hull Royal Infirmary.

GREEN, C. D., M.B.Lond., M.R.C.S., L.R.C.P.L., late Registrar, has been appointed House-Surgeon to the North-Eastern Hospital for Children, vice Meyer, resigned.

HANCOCK, WILLIAM, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., has been appointed Resident Clinical Assistant to St. Luke's Hospital, London.

HUMPHREYS, CHARLES E., M.R.C.S., L.S.A.Lond., has been appointed Public Vaccinator and Medical Officer of Health for the Llanfair District of the Llanfyllin Union, vice Jones, resigned.

NEWCOMBE, FRANK, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Ancaster District of the Grantham Union.

NICHOLSON, ROBERT HICKS BOURCHIER, M.R.C.S., L.S.A.Lond., late Assistant Surgeon, has been appointed Surgeon to the Hull Royal Infirmary.

PURDY, JAMES R., M.B., C.M.Aber., has been appointed Medical Officer for the Fourth District of the Hunslet Union.

REID, IRVINE K., M.B., C.M.Aber., has been appointed House-Surgeon to the West Norfolk and Lynn Hospital, King's Lynn.

ROBERTSON, THOMAS M., M.B., C.M.Ed., has been appointed Medical Officer for the West Butterwick District of the Gainsborough Union.

SHERBURN, JOHN, M.B., C.M., M.R.C.S., late Assistant Surgeon, has been appointed Surgeon to the Hull Royal Infirmary.

SPENCER, HERBERT RITCHIE, M.B., B.S.Lond., late Senior Obstetric Assistant and House-Surgeon, has been appointed House-Physician to University College Hospital.

THOMAS, HUGH, M.R.C.S., L.S.A.Lond., has been appointed Honorary Surgeon to the Birmingham Lying-in Charity.

THOMPSON, HENRY, M.R.C.S., L.R.C.P., L.M., late Assistant Surgeon, has been appointed Surgeon to the Hull Royal Infirmary.

Births, Marriages, and Deaths.

BIRTHS.

BENOLY.—On the 21st ult., at Leytonstone, the wife of N. Benoly, M.D., of a son.

MORGAN.—On the 22nd ult., at Gnosall, Stafford, the wife of T. Whitworth S. Morgan, M.R.C.S., of a son.

ORMEROD.—On the 16th ult., at Upper Wimpole-street, Cavendish-square, the wife of Joseph Arderne Ormerod, M.D.Oxon., F.R.C.P.Lond., of a son.

SAUL.—On the 18th ult., at Bedford-square, the wife of William Saul, M.D., of a son.

SEQUEIRA.—On the 28th ult., at Jewry-street, Aldgate, E.C., the wife of Henry J. Sequeira, M.R.C.S., of a daughter.

SMYTH.—On the 24th ult., at Holly Lodge, Brockley-road, Brockley, S.E., the wife of S. Sydney Smyth, L.R.C.P., F.R.C.S., of a son.

TREHERNE.—On the 24th ult., at Aldershot, the wife of Surgeon Francis Harper Treherne, Army Medical Staff, of a son.

WILSON.—On the 21st ult., at The Cedars, Kenninghall, Norfolk, the wife of J. H. Wilson, M.R.C.S., of a son.

MARRIAGES.

BENNETT—ROLSTON.—On the 24th ult., at the Parish Church of Stoke Damerel, W. E. Bennett, Surgeon R.N., to Sabina Elizabeth, eldest daughter of John Rolston, M.D., J.P., of Stoke, Devonport.

FARR—JAFFREY.—On the 25th ult., at the Parish Church, Barnes, Ernest Farr, M.R.C.S., L.S.A.Lond., of St. Helier's, Uxbridge-road, Ealing, W., to Ida Florence, daughter of Archibald Jaffrey, of Fern Lea, Barnes-common, Surrey.

HAMILTON—HILL.—On the 25th ult., at St. John's, Walham-green, James Hamilton, M.D., to Florence Ada Cranstoun, daughter of John Haynes Downing, Esq., and widow of the late John Joseph Hill, R.N.

SHEEHAN—BAKER.—On the 23rd ult., at Lavenham Church, J. C. Sheehan, L.R.C.P.Ed., L.R.C.S.Ed., of Grove House, to Jane, second daughter of Thomas Baker, of Lavenham, Suffolk.

DEATHS.

CÆSAR.—On the 26th ult. (whilst staying with his brother at High-road, Tottenham), Henry Augustus Cæsar, L.R.C.P.Ed., &c., eldest surviving son of the late Henry Augustus Cæsar, M.D., F.R.C.S.I., aged 50.

CRAIG.—On February 7th, at Valparaiso, John Craig, M.B., C.M.Edin., aged 23.

FAYLE.—On the 29th ult., at Eastbourne, Higginson Fayle, M.R.C.S., aged 66.

GODFRAY.—On the 12th ult., at St. Helier's, Jersey, C. Le Vesconte Godfray, Esq., M.R.C.S., L.M., L.R.C.P. (St. Bartholomew's Hospital), Surgeon to the General Hospital and Prison, son of the late Francis Godfray, Esq., Barrister-at-Law, and Advocate of the Royal Court of Jersey.

LAWSON.—On the 23rd ult., at George-square, Edinburgh, Robert James Lawson, M.B., C.M., Assistant Surgeon, R.N., late of H.M.S. *Triumph*.

SMITH.—On the 23rd ult., at Croom's-hill, Greenwich, John Gregory Smith, F.R.C.S.L.

STRATTON.—On the 16th ult. (very suddenly), at his residence, Valletort-place, Stoke Damerel, Thomas Stratton, M.D., retired D.I.G.H.F., R.N., aged 69.

TENNENT.—On the 16th ult., at Tomintoul, Banffshire, N.B., William Archibald Tennent, L.R.C.P., F.R.C.S., aged 38.

THOMSON.—On the 28th ult., at Aldershot, Surgeon-Major Alexander Thomson, aged 45.

URWICK.—On the 23rd ult. (after a few days' illness), at New Quay, Cornwall, William Urwick, M.R.C.S., L.S.A.Lond., only surviving son of W. W. Urwick, of St. George's-road, Pimlico, London.

WISE.—On the 30th ult., at Braemar-villas, West-green, Tottenham, Thomas Wise, M.R.C.S., &c., late of Plumstead, Kent.

WOOD.—On the 26th ult., at his residence, Onslow-square, Neville Wood, M.D., F.R.C.P.E., fourth son of Charles Thorold Wood, of South Thoresby, late Captain, Royal Regiment of Horse Guards (Blue), and grandson of Sir John Thorold, ninth Baronet, of Syston-park, near Grantham.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, April 5.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Communications by Drs. Joseph Walker, G. Cunningham (Cambridge), J. H. Redman (Brighton), and Messrs. C. T. Tomes, F.R.S., W. A. Maggs-Walter Colfin, S. J. Hutchinson, C. J. Boyd Wallis, F. Henri Weiss, H. G. Betts, J. H. Mummery, and A. S. Underwood.
SOCIETY OF ARTS.—8 P.M. Mr. Alan S. Cole: The Arts of Tapestry-making and Embroidery (Cantor Lecture).
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. John Lowe: Traumatic Hydronephrosis.

Tuesday, April 6.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee: The Functions of Circulation.
ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. P. W. Latham: On some Points in the Pathology of Rheumatism, Gout, and Diabetes (Croonian Lecture).
PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Roger Williams: Acute Nephritis in Lambs.—Dr. G. N. Pitt: Hydatid of Liver embedded in Syphilitic Deposit.—Dr. Sainsbury: Valvular Obstruction of Ureter.—Dr. Price (Reading): Embolism of Abdominal Aorta.—Dr. Turner: Septic Aortitis.—Mr. Sydney Jones: (1) Malformation of Foot; (2) Peculiarly-shaped Calculi (card).—Mr. Lockwood: (1) Congenital Fatty Tumour from Sole of Foot; (2) (for Mr. W. Adams) Fatty Tumours from Palm of Hand.—Dr. Sharkey: (1) Meningeal Hæmorrhage; (2) Phthisis commencing at Base of Lung (card); (3) Stenosis of Mitral, Tricuspid, and Aortic Valves (card).—Dr. Carrington: Double Intestinal Stricture.—Dr. Pye Smith: Cystic Teratoma from an Infant (card).—Messrs. Lunn and Larder: Aortic Aneurysm (card).—Dr. S. Taylor: Cerebral Tumour (card).—Mr. E. H. Fenwick: Stone impacted in Prostatic Urethra (card).

Wednesday, April 7.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. W. S. A. Griffith and others.—Dr. Matthews Duncan: On Contraction, Inhibition, and Expansion of the Uterus.—Dr. Coates: A case of Labour in a Primipara suffering from Mitral Disease.—Dr. Amand Routh: A case of Serous Perimetritis.—Dr. Champneys: Note on the Artificial Production of so-called Lymphatic Varix.
SOCIETY OF ARTS.—8 P.M. Mr. J. S. Hodson: Preparation of Drawings for Photographic Reproduction.

Thursday, April 8.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Dewar: Electro-Chemistry.
ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Mr. W. H. Stone: Man as an Electric Conductor, Condenser, and Electrolyte (Lumleian Lecture).
SOCIETY OF ARTS.—8 P.M. Mr. James Boyd: Asbestos and its Applications.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

THE CHAIR OF PHYSIOLOGY AT ABERDEEN.

Professor Haycraft writes to ask to be allowed to contradict a statement which appeared in our issue of Feb. 6th that he is a candidate for the above post.

Mr. J. M. Edmunds.—The London School of Dental Surgery, Leicester-square; or the National Dental College, Great Portland-street.

THE POTASSIO-MERCURIC-IODIDE TEST.

To the Editor of THE LANCET.

SIR,—Works published within the past year, containing references to albumen tests, still recommend the potassio-mercuric iodide as being an exceedingly delicate and trustworthy reagent, with the additional advantages of being handy and easily applied. Of course by itself it is useless, unless citric or acetic acid be added to the urine, as in testing with potassium ferrocyanide or sodium tungstate. Now, everybody admits that potassio-mercuric iodide and citric or acetic acid will precipitate albumen. But it is a very different matter to admit that a precipitate given in any clear urine by these reagents is necessarily due to albumen. As a matter of fact, it may not be due to albumen. I cannot speak with anything like certainty regarding the other two reagents (potassium ferrocyanide and sodium tungstate), though I believe they are fallacious; but from a number of experiments I made in the London Hospital in 1883 with the potassio-mercuric iodide, I can confidently say that if sufficient time be allowed it will give a precipitate with almost every specimen of urine put to the test, even should no trace of albumen be detected by any other known reagent. This circumstance may possibly be explained by supposing the potassio-mercuric iodide to give increased effect to the precipitate of mucin which the acids have the power of producing. It is therefore not to be wondered at, though this test be found so remarkably delicate, the true explanation being that it is remarkably delusive and dangerous.

I am, Sir, yours truly,

Wick, March 17th, 1886. A. G. AULD, M.B., &c.

Mr. James McCulloch, M.R.C.S.—The name of the dentist mentioned is in the Dentists' Register for this year, as being in practice before 1878. He therefore has a legal standing.

VENTILATING SEWERS.

To the Editor of THE LANCET.

SIR,—Without doubt you are right in your statement that an efficient, safe, and cheap method of ventilating sewers is by pipes carried up above the buildings. Perhaps it would interest some of your readers to learn that recently an invention was patented by W. M. Hawkins, 59, Albion-street, Birmingham (No. 8108-84), by which clay pipes are securely held together with iron or steel hooping running through their edges to hold them in position. They can be carried up any height without any outside support. They cannot fall down, and no foul air can escape through the places where they are joined together. When once fixed they cannot move. The method is not expensive. I have also seen it tested as stove pipes, starting from the floor and going straight through the roofs of buildings.

I am, Sir, yours faithfully,

Clare, March, 1886. J. JOHNSON.

EXTRAORDINARY SUBJECT FOR A PRIZE ESSAY.

THE Paris Academy of Medicine has chosen an extraordinary, not to say an impossible, subject for a prize essay this year—"Préciser par une Série d'Observations s'il existe un Traitement Abortif de la Syphilis Confirmée" (to determine by a series of observations if there exists an abortive treatment of confirmed syphilis), upon which M. Diday has suggested that the Academy must have been seized with an economical fit, and that it would be interesting to see if anyone could manage to write a paper of 400 pages on abortive treatment directed against confirmed syphilis.

Mr. John Woodland.—It is certainly right to ask permission before using a name or case publicly; but we quite perceive that this rule might be broken from mere inadvertence.

A Student.—Harrison Cripps' or Allingham's work.

COLOUR-BLINDNESS; ANOSMIA; GLAUCOMA.

To the Editor of THE LANCET.

SIR,—The letter of Mr. Piesse in THE LANCET of March 13th, p. 528, has indirectly given rise to one from Dr. Nicholas, and to another from "M.D. Durh.," in to-day's issue (p. 621). Both these letters, though somewhat apart from the original subject—colour-blindness among medical men—possess points of interest of their own.

I am not in a position to say much in reply to Dr. Nicholas; but I believe it is generally admitted that defects in the sense of smell, when they occur, are rather variations in degree of appreciation than confusion of odours. If the latter exist as a pathological result, I should fancy that it might in most cases be referred to an interference with the purity of the odour presented to the nervous apparatus on account of some fetid discharge in the nasal fossæ. As the result of imperfect development, I doubt whether we have anything parallel to colour-blindness. There may, of course, be a general lack of intelligence, or a want of education, on the part of some individuals which might lead a casual observer into the belief that odours are sometimes confused. But this confusion would then be merely the result of ignorance, and would in no way be comparable to colour-blindness. I advance this opinion in all humility, and beg to add that I am quite open to correction. As to the odour of chloral hydrate, I feel sure I am right in saying that it is universally considered to resemble that of melons. We have Dr. Garrod's authority on this point. I confess I have not read the evidence given by Dr. Stevenson; but I imagine the word "lemon" to be merely a typographical or reporter's error, in which the letters have become misplaced.

With regard to the suggestion made by "M.D. Durh.," that the word "glaucoma" is derived from γλαυξ, γλαυκος, an owl, I own I am unconvinced. I do not deny that many words are worse parented, if I may be allowed the expression; but on looking into the matter a little more closely, I think we shall be led to the conclusion that the tint of sea-green noticed in many cases of glaucoma really did give rise to the name of the disease. Mr. Brudenell Carter says: "In some of the more acute forms of increased tension the pupil presents a clouded aspect of a greenish colour; and it was to cases of this class that the word glaucoma (from γλαυκος, sea-green) was originally applied, at a time when the pathology of the condition was not understood." At the time to which Mr. Brudenell Carter alludes there was no doubt a large proportion of cases of increased tension in which the greenish colour was absent; but these cases, be it observed, were not placed in the same category. The inference is obvious. When it became known to pathologists that the greenish tint seen in the pupillary area was not an essential feature in every phase of the disease, the meaning of the term "glaucoma" was stretched to include all cases in which a block in the drainage system of the ligamentum pectinatum became evident by increased tension, cupping of the disc, &c. In conclusion, I may say that I have drawn the attention of some of my *confrères* in ophthalmic surgery to the letter of "M.D. Durh.," and the unanimous opinion is in favour of the accepted derivation.—I am, Sir, yours truly,

A. ST. CLAIR BUXTON, F.R.C.S.,
Assistant-Surgeon to the Western Ophthalmic Hospital.

Orchard-street, W., March 27th, 1886.

M.R.C.S.—The Medical Defence Associations exist for bringing such persons to justice; but, unfortunately, they meet with only a limited support from the profession. A person who *falsely* uses titles which imply that he holds medical qualifications is a fair subject for prosecution.

M. PASTEUR'S INOCULATIONS.

To the Editor of THE LANCET.

SIR,—Since it is likely that a body of commissioners will be formed to investigate Pasteur's method of inoculation for hydrophobia, and as several eminent members of the medical profession have been asked and consented to serve on such a commission, might I, as a member of the Royal College of Veterinary Surgeons, suggest that one of the commissioners be a veterinary surgeon. Considering the veterinary profession has so much to do with rabies canina, I think it is justly entitled to some share in the honour. Are we all not very much indebted to Mr. George Fleming, who has always taken a very great interest in the subject, for a great deal of information concerning rabies, and what more fitting acknowledgment could be bestowed on him than that he should be elected as one of the commissioners?—Yours obediently,

Manchester, March 29th, 1886. JOHN MOORE, M.R.C.V.S.

ACTION FOR MEDICAL ATTENDANCE IN AN ALMSHOUSE.

THE *Dundee Advertiser* of March 19th and 27th respectively contain the report of a very just action at law by Dr. Lawrence of Brechin, N.B., to recover £16 for a year's medical attendance on the late Miss Christina Jamieson, and of a very just decision of the sheriff substitute. Miss Jamieson, an old lady, was an inmate of the Brechin poorhouse—a sort of almshouse. But Miss Jamieson was not poor. She was not a pauper; for she paid latterly 10*s.* a week for her board, and died leaving a few hundred pounds to her relatives. Under these circumstances, it was not unreasonable that Dr. Lawrence should look to her trustees for payment. The sheriff entirely supported his claim, and allowed him £12 12*s.* and expenses of the suit. He held that the parochial board had nothing to do with Dr. Lawrence's claim, and that he, *qua* their officer, did not attend Miss Jamieson. The almshouses of Scotland are not on the same legalised footing as the workhouses in England; and Dr. Lawrence's case will be regarded by Scotch practitioners as one of some interest, and involving a question that has not been raised before.

Mr. A. Crespi.—Messrs. Longmans have published a book, entitled "Louis Pasteur, his Life and Labours," written by his Son-in-law, which was reviewed in THE LANCET, May 2nd, 1885.

Surgeon Lees Hall.—We regret we cannot comply with our correspondent's request, as to do so would be contrary to our custom.

THE PHARMACOPŒIA TEST FOR PEPSIN.

To the Editor of THE LANCET.

SIR,—In Dr. Murrell's interesting note on "Pepsin as a Digestive Agent," published in your issue of Feb. 27th, reference is made to the test for pepsin adopted in the new edition of the Pharmacopœia. Dr. Murrell sums up the differences between the tests of the 1867 and 1885 Pharmacopœias, and obtains as a "net result that our standard has been raised 71·5 per cent., for which," says he, "too much gratitude cannot be shown." This conclusion appears to be based upon the assumption that pepsin is 16 per cent. more active at 130° F. than at 98°. Experiment will prove that the increase in the activity of pepsin at the higher temperature is much greater than this.

The test for pepsin adopted in the Pharmacopœia of 1885 is that proposed by me as an amendment to the then official one, in a paper read before the British Pharmaceutical Conference in 1881, and printed in the "Year Book of Pharmacy" for that year, p. 417. It has been in constant use in my laboratory since that time. It is so simple and expeditious that Dr. Murrell's advice, "Test your pepsin," can be followed by all, to the great advantage of their dyspeptic patients. My original paper contains some rather important details of manipulation, necessarily omitted in the brief Pharmacopœia directions. The white of egg having been pressed through the wire gauze should be lightly rubbed in a glass mortar during the addition of the acidulated water, so as to separate the vermiform particles; this cannot be done by merely stirring. I always use wide test-tubes standing in a large beaker of water as a water bath; each tube is provided with a small glass stirrer. Half a dozen samples can in this way be tested at the same time under absolutely similar conditions. Dr. Murrell's opinion that "to give only from two to five grains of pepsin at a time is a palpable absurdity," may possibly be modified by a consideration of the fact that whilst in our laboratory experiments the products of digestion remain in the digesting apparatus, and gradually retard, and finally stop, the action of the ferment, in the stomach these products are constantly removed as digestion goes on. It must not be supposed that 100 grains of egg albumen are all that two grains of B.P. pepsin, or the minimum dose of a fluid preparation of pepsin, will digest in half an hour under other conditions, and with other surroundings! The following experiment will demonstrate the contrary. Ten times the Pharmacopœia quantity of egg and acidulated water were taken—that is, 1000 grains of egg and ten fluid ounces of acidulated water; these were placed in a beaker; 100 grains of egg and one fluid ounce of acidulated water were placed in a large test-tube and stood in the beaker; and the whole heated to 130° F. One fluid drachm (the minimum dose) of an active fluid preparation of pepsin was then added to both beaker and test-tube, the temperature maintained constant, and the contents of both stirred occasionally. When the egg in the test-tube had all dissolved, which in this experiment occupied twenty-five minutes, the contents of the beaker were thrown on a fine muslin filter and drained; the undissolved egg weighed 220 grains. Here then a dose of pepsin had dissolved 780 grains of egg in ten ounces of fluid, whilst a similar dose had dissolved 100 grains in one ounce of fluid. Another attempt was made to approach more nearly to the conditions under which pepsin acts in the stomach. The egg, acidulated water, and pepsin were placed on a parchment dialyser and floated on a bowl of acidulated water. In this case it was found that enormously more egg was dissolved in the dialyser than in a test-tube containing the same mixture. I fear my communication is already too long. I will only add that in testing B.P. pepsins against liquid preparations of pepsin the only fair way is to take the minimum dose of each—say, two grains of B.P. pepsin and one fluid drachm (the usual minimum dose) of fluid preparations; or one part of solid against thirty parts of liquid. I observe that Dr. Murrell took in his experiments one grain of dry pepsin and ten grains of fluid preparations. Obviously his results may have been misleading.—Yours obediently,

F. BADEN BENGER, F.C.S.

Exchange-street, Manchester, March 8th, 1886.

MINCING MACHINES.

IN reference to a letter on this subject which appeared in our issue of March 13th, Messrs. J. Coppard and Co., of New Charles-street, E.C., write to say that the machines manufactured by them are free from the objection referred to by the writer of the letter, being made entirely of iron.

Mr. Jas. W. Smith.—The College of Surgeons issued a circular to their Fellows, intimating that the space at their disposal was very limited, and requesting those Fellows who wished to be present to send in their names, when the available seats would be assigned by drawing lots. A notice to a similar effect, addressed to the Members, was also published in our advertising columns of March 6th. As regards the College of Physicians, we believe that all the Fellows and Members had the opportunity afforded them of being present, and that the licentiates were taken in order of seniority. The authorities of the two Colleges seem to have used every endeavour to deal fairly with all who had any claim to be present.

Dr. Abrath.—We are not prepared to again open up the case.

PHOSPHORUS.

To the Editor of THE LANCET.

SIR,—As it is probable that the discussion at the meeting of the Clinical Society on March 12th on Mr. Hutchinson's case of necrosis may have left some of your readers in perplexity as to the possibility of phosphorus producing necrosis when given in a pill over a long period, the following extract from an undoubted authority will be read with interest.

Writing upon the action of phosphorus, Dr. Lauder Brunton says: "Its action upon the bones is somewhat peculiar, and has been fully investigated by Wegner. ..... In men exposed to the fumes of phosphorus—e.g., those employed in the manufacture of lucifer-matches—caries of the lower jaw is a frequent occurrence. This is *not* due to the action of the phosphorus *after absorption into the circulation*, but to the *direct effect of the fumes* upon the bone itself. For it has been shown that when a bone of an animal *fed upon phosphorus* was exposed, *no carious change took place*; but if one were exposed to the fumes, caries was produced, and amongst lucifer-match makers it has been noticed that only those who have carious teeth suffer from necrosis." (Brunton's Pharmacology, Second Edition, page 638.)

Again, in Dr. Ringer's Handbook of Therapeutics (Seventh Edition, page 304), we find the following confirmatory statement:—"The effects of chronic phosphorus poisoning have lately been elaborately worked out on animals by Dr. George Wegner, and with singular results. It has long been known that workmen exposed to the fumes of phosphorus are liable to necrosis of the jaw, and Dr. Wegner believes that this results from the direct action of phosphorus on denuded bone, and that necrosis will *not* set in unless, through wounds or carious teeth, there is some destruction of the soft tissues, thus enabling the phosphorus to reach the exposed bone. In support of this view, he adduces the following reasons: (1) If the periosteum of an animal is severely wounded, and phosphorus is given *in the form of a pill even for months*, the periosteal changes do *not take place*. (2) When the tibia of a rabbit is partially bared, a healthy granulating wound is soon established; but under exposure to a phosphorus atmosphere, periostitis is set up, similar to that in the jaw. (3) Many workers in phosphorus escape, whilst those who do suffer have carious teeth."—I am, Sir, yours faithfully,

Beckenham, March 24th, 1886. E. A. KIRBY, M.D.

Chyluria.—Chylous urine contains either a coagulum or flaky clots from the breaking up of the former in the great majority of cases. Unlike a mixture of urine and milk, chylous urine is further recognised by the fact that "the fatty matter almost invariably occurs in the form of excessively minute granules." The presence of large fat globules and the absence of a coagulum afford very strong evidence that the fluid is other than chylous urine.

X. Y. Z.—Our correspondent should refuse to give a certificate, and leave the responsibility with the coroner.

"FEMALE LABOUR IN COLLIERIES."

To the Editor of THE LANCET.

SIR,—Having seen an annotation under the above heading in your last issue (p. 605), I beg to submit that, in my opinion, the writer has judged both the work and the workers erroneously. As I have lived all my life in a colliery district, and have also served my indentures with a surgeon to a large colliery, I think I may say that I have seen the "Lancashire pit-woman" in all phases of her character. I feel sure that any person visiting the home of the female labourer on the pit brow will find that the household duties are as well performed as in any other household in a colliery district. Her morals will bear comparison with either those of the factory operative or the daughter of the agricultural labourer; for they are equal, if not superior, to both. Their clergymen bear witness that they do not suffer in this respect. Physically, their muscular development is surpassed by no woman. I think any colliery surgeon will bear me out when I say that they do not suffer from a health point of view. Now, when they are not injured morally, physically, or in a domestic sense, why should they be hindered from bearing their share of the world's work?—I am, Sir, yours truly,

ROBERT STOPFORD, L.K.Q.C.P.I.,
Late Medical Officer, Perim Island, Red Sea.

Appley Bridge, Wigan, March 30th, 1886.

A REMARKABLE DISLOCATION OF THE THIRD CUNEIFORM BONE.

To the Editor of THE LANCET.

SIR,—The following case is, I think, sufficiently rare to deserve being placed on record.

In February of last year an accident happened opposite my house, and the sufferer was at once brought into my surgery. I had witnessed the accident. The patient, a man of about thirty-five years, of pale and relaxed fibre, showed upon examination a dislocation of the external cuneiform bone. The luxation was somewhat peculiar; the entire bone, being displaced upwards, lay upon the inner edge and dorsum of the os cuboides. About half the dorsal surface of the cuboid bone was covered by the plantar surface of the cuneiform. The displaced bone could be very distinctly seen through the stretched skin of the dorsum of the foot, as if a cube had been placed under it. The patient suffered very little pain, and the bone could be easily reduced by mere pressure upon the dorsal surface, with only the slightest possible extension of the toes. When the foot was flexed by the will of the patient the luxation recurred. The member was placed in an appropriate splint, with a graduated pad over the displaced bone. The man was then removed to his home, some miles away. He thus passed from my care, and I have heard nothing further from him. The accident happened thus:—The man was endeavouring to mount a barebacked horse, which was standing close to the kerb-stone. He threw his right leg over the animal, which started forward with a bound, dislodging him backwards. As the horse passed from under him, he came down upon the edge of the kerb-stone with his left foot flexed and abducted. The sole was also somewhat everted. I am, Sir, yours faithfully,

HAYGARTH ADDISON, L.F.P.S.G.

Seven Sisters-road, N., March 23rd, 1886.

Dr. C. W. Pilgrim.—The reference probably was to the Edinburgh Medical Missionary Society, the secretary of which is the Rev. John Lowe, 56, George-square, Edinburgh.

L.R.C.P.—Erichsen's Surgery; Pepper's Surgical Pathology.

"PRACTICE AT THE CAPE."

To the Editor of THE LANCET.

SIR,—Having returned this month from the Cape Colony after a residence there of some years, I can endorse most of what "Cape Colonist" says in answer to "A Constant Reader's" letter in THE LANCET of March 20th (p. 621). The last three years have been years of drought, with consequent immense pecuniary loss to the farmers—the producers of the country. The harvest of this year, however, owing to abundant rainfall, promised to be a plentiful one: and the colony is very elastic, so that with a few good seasons the prospects of anyone intending to settle in South Africa would be much brighter. At the present time I would not recommend a doctor to venture out there. Still there are one or two openings in up-country places, and if "A Constant Reader" will communicate with me, I should be happy to supply him with any further information. In the Government *Gazette* for the colony vacant "district surgeoncies" are advertised from time to time, and any medical man leaving for the Cape would find it of great advantage in being able to go straight to such an appointment. When I left the Government had in view the establishment of a district surgeon at Tsolo, in Tembuland, with a salary of £250 per annum, with allowances and practise. But to secure these billets it is advantageous to have local influence. I am, Sir, yours obediently,

Dartford, March 30th, 1886. HENRY H. STURGE.

PLASTIC BRONCHITIS.

To the Editor of THE LANCET.

SIR,—I shall be indebted to you if you will kindly insert the following case, which has baffled all treatment, as far as a cure is concerned.

The patient, a female about middle age, is suffering from plastic bronchitis, and regularly expectorates large quantities of membrane, which unquestionably come from the bronchi and trachea. She has periodical attacks (every week or nine days) of dyspnœa, followed by casts of membrane which are expectorated with more or less bloody mucus attached to them. Some of the casts are as large as 1½ in. square. As soon as the attack is over she will be comparatively well for a week or so, until another attack ensues. I have prescribed all the usual remedies, but without permanent effect, and should be greatly obliged to any of your readers who have met with similar cases for their advice, either privately or through THE LANCET.—I am, Sir, yours truly,

March 26th, 1886. CYMRO.

"DIPHTHERIA AND PIGEON-KEEPING."

To the Editor of THE LANCET.

SIR,—In your issue of March 20th, p. 576, it is stated that M. Destrée of Brussels has called attention to the fact that there may be some connexion between pigeons and diphtheria. In a paper on an epidemic of diphtheria observed in Naples in 1871, published in the *Edinburgh Medical Journal* in 1872, and subsequently copied nearly *in extenso* in the *Medical Times and Gazette*, and in my graduation thesis in the University of Paris in 1881, I pointed out the fact that in the epidemic in question the wells were largely contaminated by the excrement of pigeons and poultry, and in some cases by that of horses. I also suggested guano under certain circumstances as a possible factor.—Yours truly,

Venice, March 22nd, 1886. J. A. MENZIES, M.D. Ed. & Paris.

Digitized by Google

"DOCKED FEES."

To the Editor of THE LANCET.

SIR,—In reference to the communication of a correspondent in your last issue (page 604), on what he terms with more force than elegance "docked fees," will you kindly allow me, in the spirit of your motto, "audi alteram partem," space for a few remarks.

Far from agreeing with the tone of your correspondent's letter, which attributes to parsimony what I prefer to believe in the majority of cases is due to a laudable delicacy, I would merely observe that there has long been felt a certain amount of awkwardness in tendering to a doctor the extra silver coin the guinea fee necessitates. The guinea fee is a nuisance that has long been felt, and many doctors, in Ireland at least, have long since allowed it to drop into a silent grave. The inconvenience applies to many other cases. School fees, lawyers' fees, hospital fees, fees for classes of every description, are still reckoned in guineas, much to the inconvenience of the public. Quite different was the case when the guinea was the standard gold coin of the realm. It would have been quite as anomalous then to tender a professional man a fee of twenty shillings, the guinea being the legal coin, as it is now to tender a fee of twenty-one shillings, the sovereign being the legal coin. It is high time the medical profession separated themselves from this obsolete rate of remuneration. Let your correspondent recollect that if his fees are slightly diminished by the substitution, there will be a corresponding gain in other respects. He will effect a saving in his children's school fees, in his son's medical fees (should he follow in his father's footsteps), and should he unhappily tempt the law's delays, more important still, in his legal fees. Let the guinea fee follow the obsolete coin, and it will be found that the theoretical loss will in reality become an immense gain.

I am, Sir, yours truly,

March 30th, 1886. M.B. DUB.

INCOMPATIBLES.

To the Editor of THE LANCET.

SIR,—In the ninth edition of Garrod's Materia Medica, on page 326, it is stated that under the head of incompatibles neither liquor potassæ nor any other caustic alkaloid should be prescribed with tincture or extract of henbane, *as the virtues of the latter drug are completely neutralised.* (The italics are my own.) On page 311, prescription No. 69, of Tanner's Index of Diseases, the following prescription will be found:—℞ Liquoris Potassæ, ♏ x-xv.; Tincturæ Hyoscyami, ♏ xx.; Infusi Bucco, fl. ℥jss.: Ft. Haustus. If the statement in "Garrod" is correct, then the prescription in "Tanner" is worthless. Perhaps you or some of your readers can kindly inform me whether, after all, it is no more harm to prescribe liquor potassæ and hyoscyamus than to order bark and bichloride of mercury, which is often done, though these drugs are said to be incompatible.

I am, Sir, yours faithfully,

March 23rd, 1886. DUBITANS.

FOOD FOR THE DESTITUTE.

To the Editor of THE LANCET.

SIR,—Seeing an annotation in your issue of March 13th, p. 505, on nutritious food for the poor, I venture to forward you the following information upon that now absorbing subject. I have, with the assistance of a lady, for the last three weeks supplied to destitute families in my neighbourhood an average of 300 dinners a week, which might be termed "Irish stew," composed of stock made from bones, onions, carrots, rice, potatoes, and beef or mutton without bone, each person having from four to five ounces of the latter at a cost of a fraction under twopence-halfpenny each. We supplement this by the addition of one hundredweight of coal to each family. I remain, Sir, yours truly,

March 24th, 1886. M.R.C.S.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—In your otherwise correct report of the case of multiple phlebitis read at the Islington Medical Society, I beg to state that the published temperatures were carefully taken in the *mouth*, not in the rectum, as reported.

I am, Sir, yours faithfully,

Green Lanes, N., March 27th, 1886. ALEXANDER MORISON, M.D.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. F. S. Eve, London; Dr. Sansom, London; Mr. St. Clair Buxton, London; Mr. W. Fraser, Aberdeen; Dr. McNab, Bury St. Edmunds; Mr. H. Croonian Lectures

ON

SOME POINTS IN THE PATHOLOGY OF RHEUMATISM, GOUT, AND DIABETES.

Delivered at the Royal College of Physicians of London, April, 1886.

BY P. W. LATHAM, M.A., M.D., F.R.C.P.,

DOWNING PROFESSOR OF MEDICINE, CAMBRIDGE; SENIOR PHYSICIAN TO ADDENBROOKE'S HOSPITAL.

LECTURE II.

WHAT in rheumatism is the starting-point of the morbid process? Is there such a thing as the rheumatic poison? If so, what is it, and what is the nature of the change which takes place as the result of its action? Let me in the first place enumerate the more salient features of the disease as gleaned from clinical experience. An individual after feeling out of sorts for two or three days, perhaps after a chill wakes up in the morning with one of the joints stiff and tender; soon afterwards it swells, and motion causes pain. Other joints now become affected—the knees, wrists, elbows, ankles, and the smaller joints of the hands and feet. There are pain, tenderness, increased heat, swelling, and redness of the skin. The tendency of these to shift from joint to joint is a remarkable feature of the disease. The slightest motion becomes insupportable; even vibration of the room or of the bed causes suffering. There is more or less febrile movement, the temperature ranging from 102° to 104° or higher, and generally more or less sweating, the odour of which is characteristic. The tongue is coated, thirst is generally a marked symptom, and the urine is turbid with lithates and has a strong acid reaction. The more acute and severe the case, the more profuse and acid is the perspiration, and the larger the amount of lactic acid which it contains. This last feature has led to the supposition that in acute rheumatism there is excessive formation of this acid, which, circulating through the system, gives rise to the symptoms which accompany the disorder. It is a theory which has got a very firm hold of the minds of many physicians, and is probably the one most generally adopted. There is so much to be said in its favour that until recently I unhesitatingly accepted it. I hope to show now that, though lactic acid is formed in excess in the disease, and its presence in the blood modifies the symptoms in some degree, it is not the chief agent in producing them. Other factors are at work giving rise to the characteristic feature of rheumatism—viz., the affection of the joints—as well as to some of the other symptoms which I have enumerated, and the excessive formation of this acid must be regarded more as one of the symptoms than as the cause which gives rise to them. The lactic acid theory, however, has furnished me with my true starting-point. In attempting for five or six years to arrive at some satisfactory explanation of the phenomena of this disorder the line of argument which suggested itself to my mind was much as follows:—

1. Lactic acid is the *materies morbi* in rheumatism.

2. According to the views of some authorities the natural source of lactic acid in the system is glucose—which is first transformed into lactic acid and then further oxidised into carbonic acid and water.

$$\underset{\text{glucose}}{C_6H_{12}O_6} = 2\underset{\text{lactic acid}}{C_2H_4\begin{Bmatrix}OH\\COOH\end{Bmatrix}}$$

$$\text{and } 2\underset{\text{lactic acid.}}{C_2H_4\begin{Bmatrix}OH\\COOH\end{Bmatrix}} + 6O_2 = 6CO_2 + 6H_2O$$

3. By the so-called "diabetic puncture" the metabolism of glucose in the system can be arrested; sugar appears in the urine, and we have the phenomena of diabetes. Changes, therefore, in the medulla oblongata entirely arrest the metabolism of glucose, and if so, should this be true, would it be possible by modifying these changes in the medulla partially to arrest the transformation of glucose into CO_2 and H_2O at the intermediate stage of lactic acid, and so develop rheumatism? That is to say, have neurotic conditions, have changes in the medulla oblongata, anything whatever to do with the symptoms which are associated with rheumatism?

These were the hypotheses with which I started. But I have tried to show in my previous lecture that lactic acid in the tissues is formed not from glucose, but from the nitrogenous molecules of the tissues—namely, the cyan-alcohols $CH_3.CH\begin{Bmatrix}OH\\CN\end{Bmatrix}$ and $CH_2CH_2\begin{Bmatrix}OH\\CN.\end{Bmatrix}$ My second hypothesis therefore falls to the ground, and with it the third to a very large extent. Certain points, however, presented themselves to me during the consideration of the subject, which seem to connect the disorder with changes in the nervous system, and to furnish a theory as to the causation of rheumatism, by which an explanation may be offered not only of the way in which the symptoms are produced, but also of the action of some of the remedies which have been successfully employed in the treatment of the disease. To these points let me now specially invite your attention.

As a first step in demonstrating the connexion of rheumatism with changes in the nervous system, let me refer to some nerve lesions which are associated with changes in the nutrition of the joints. In respect to this I find that more than fifty years ago the late Dr. J. K. Mitchell[1] advanced a theory of the pathogenesis of rheumatism which connected it with affections of the spinal cord. My own view, which localises the controlling action of the nervous system in the disorder, chiefly in the medulla oblongata, was formed quite independently; it was only, in fact, quite recently that my attention was directed to Dr. Mitchell's views by finding a reference to them on reading a most admirable work, abounding with interesting facts, by his son Dr. Weir Mitchell on "Injuries of Nerves." I here discover, however, some most important links in the chain of evidence supporting my theory, which I will place before you; and after referring to other cases of a similar kind I shall then attempt to point out the way in which the nervous centre is affected both in gout and rheumatism—how, in fact, the rheumatic poison is developed and how it acts.

In a work on "Gunshot Wounds and other Injuries of Nerves," by Drs. Weir Mitchell, Moorhouse, and Keen, of the United States Army,[2] there is the following statement:—

"*Alterations in the nutrition of joints.* Again we call attention to a peculiarity of nerve injuries which we believe to have been overlooked. Like the altered nutrition of the skin, the symptom which we are at present considering occurs at any time after the first few days. It consists essentially in a painful swelling of the joints, which may attack any or all of the articulations of a member. It is distinct from the early swelling due to the inflammation about the wound itself, although it may be masked by it for a time; nor is it merely a part of the general œdema which is a common consequence of wounds. It is more than these—more important, more persistent. Once fully established, it keeps the joints stiff and sore for weeks or months. When the acute stage has departed, the tissues about the articulations become hard, and partial ankylosis results, so that in many cases the only final cause of loss of motion is due to this state of the joints. Of all the agencies which impede movement it is the most difficult to relieve. Were we asked to state in what essential respect these lesions differ from subacute rheumatic disease of the same parts, we should certainly be at some loss to discern a difference. The subject suggests certain interesting reflexions. We have ourselves seen cases of spinal injury in which rheumatic symptoms seemed to have been among the consequences; and four such instances of striking character are to be found recorded in a paper by the late Prof. J. K. Mitchell, *Am Jour. of the Med. Sci.*, vol. viii., p. 55. Upon the hints which were thus furnished, Dr. Mitchell was induced to consider rheumatism as of spinal origin. His treatment,[3] founded on this view, was most successful, and is still used and recognised in this country. Modern pathologists have traced the causation of rheumatism to a strictly chemical source; but no one can avoid seeing that there may be a cause beyond this, even though the chemical conditions be still considered as essential links in the chain. Thus, after all, the true origin may be spinal, or, at all

[3] The treatment he adopted was to apply from eight to sixteen cups, abstracting about as many ounces of blood, to the cervical or lumbar spine, according as the upper or lower extremities were affected, and follow the cupping, if this did not afford relief, by the application of blisters to the spine.

events, the indisputable fact that there are rheumatisms depending for existence on neural changes may aid us hereafter to discriminate varieties of type among the forms of rheumatic disease. It were easy to dwell upon this subject, but enough has been said to show that subacute inflammation of joints may be brought about by nerve lesions, and to direct medical thought anew in a direction which seems favourable to its true and rational progress."

In a subsequent work, the work to which I have already referred—"On Injuries of Nerves,"[4]—Dr. S. Weir Mitchell writes:—

"Of all the various forms of mischief wrought by nerve wounds, the most intractable and disabling are the curious inflammatory states of joints to which we were the first to call attention. ..... In a certain number of nerve wounds, notably most often in those of the upper extremities, one or more of the joints in the wounded limb become swollen. The nature of the injury does not seem to influence the case, as I have seen it follow dislocations, ball wounds, and contusions of nerves, while in an interesting case of Dr. Packard's it was one of the consequences of compression of the sciatic nerve by a tumour. More lately, in the service of my friend, Dr. J. A. Brinton, at the Philadelphia Hospital, I saw a man who had extensive joint lesions, owing to the brachial nerves having suffered during the dislocation, or upon the subsequent reduction of the humerus, so that I suspect these troubles are more common than has been supposed.[5] In one case the joints of the fingers became swollen and tender on the third day after ball wound of the brachial plexus, but usually the swelling appears much later, and, like the glossy skin, is frequently the offspring of secondary neuritis. Often masked at first by the general inflammation of the limb, or concealed by the œdema so common after nerve wounds, it is more persistent than these, and, as they fade, begins to assume importance. We may then have one articulation—and if only one, a large one—involved, or perhaps all the joints of a finger or every joint in the hand or of the entire limb may suffer. The swelling is never very great, the redness usually slight, and the tenderness on touch or motion exquisite. This condition of things remains with little change during weeks or months, and then slowly declines, leaving the joints stiff, enlarged, and somewhat sensitive, especially as to movement. A small proportion of such cases find ready relief, but in many of them the resultant ankylosis proves utterly unconquerable, so that it is vain to break up the adhesions under ether, or to try to restore mobility by manipulation of splints. All alike fail, and serve only to add to the essential tortures of the accompanying neuralgia and hyperæsthetic states of skin. Since writing my last paper[6] I have met with some of the former patients who suffered with these troubles, but in no case originally very severe was there any great gain—indeed in most of them the joints had become every year more stiff and useless. It is, then, quite clear that injuries of the spine, diseases of this organ, and of the brain, and wounds, or any form of lesions of nerves, are capable of developing in the joints inflammatory conditions, usually subacute, and which so precisely resemble rheumatic arthritis in their symptoms and results that no clinical skill can discriminate between the two. In this state it were well to leave the subject. The chemical theories have crumbled, and, in the growing tendency to believe that rheumatism may have more forms than one, it may not be amiss to recall the facts to which we have contributed, and which are well illustrated by the following cases. Other and more severe examples will be found in cases appended to the later chapters of this work.

"CASE 30. *Gunshot wound of the right brachial plexus: causalgia: tremor: arthritic lesions: nail-changes: acid sweats: hyperæsthesia: little loss of motion from paralysis: great gain under treatment.* B. D. L——, aged forty-three, a farmer from Maine. Enlisted July, 1862. He was healthy to the date of his wound, received July 2nd, 1863, at Gettysburg. While kneeling and aiming he was shot in the right side of the neck. He felt pain in the wound, but none down the arm. He spun around, feeling stunned, and fell on his back, not unconscious. In five minutes he arose and walked to the rear, where the wound was dressed with cold water, no splint being employed either then or later. At first all motion was lost. In an hour he could move his finger and abduct the arm, but not flex it. He thinks sensation was perfect, except as to the ulnar distribution. Within an hour he had severe earache, and pain in the shoulder, arm, and forearm. During the second week he began to have burning pain in the hand. At this time, which probably marked the onset of neuritis, the shoulder-joint grew stiff, then the elbow, and lastly all of the fingers. This condition was excessively painful, and remained unchanged. The tremor which is constant in the upper arm muscles began the day of the wound, and had not ceased on his admission to our wards. On admission, October, 1863, it was noted that the ball had entered the right side of the neck, in front, three inches above the clavicle, in the outer edge of the trapezius. The missile passed downward and outward, and struck the anterior edge of the supra-spinal fossa of the scapula, five inches external to the spine of the first dorsal vertebra. Both wounds sloughed, leaving scars 1½ in. in diameter. The patient is well and florid; the shoulder is motionless from stiffness; the lower joints are alike stiff, swollen, red, and painful; the arm, semi-prone and flexed, is carried across the chest, supported by the sound hand. He has slight motion throughout, but the effort causes fibrillar tremor and exquisite pain. The sense of touch is everywhere good, save that there is slight numbness of the back of the hand and forearm. Some causalgia is felt in the palm, but no other pain, except on movement. The palm is thin and red or purplish, and on it the patient uses water now and then as a dressing; there is no atrophy; the wound is healed, but tender, as are also the upper nerve tracks. Muscular hyperæsthesia of the deltoid and triceps is present. The nails are remarkably curved, the hair is scanty, the sweat ill-smelling and acid. The shoulder muscles alone have lost electro-muscular contractility (induction current). Under ether, the joints, when moved, are found to be free from well-marked organic adhesions. Passive motion and electricity caused speedy gain in movement, and in February, 1864, he was able to move all the joints with diminished pain. The muscles were at this time sensitive to induced currents, and the numbness and causalgia had nearly disappeared. He was allowed a furlough, at the expiration of which he deserted. This case is valuable as an example of arthritic changes, extreme in character, with very little sensory or motor paralysis, and seemingly aided by treatment."

Again, Sir William Gull[7] has recorded the following two cases, and his remarks upon them are so suggestive that I quote them in full:—

"CASE 27. *Acute rheumatic (?) affection of the larger joints; paraplegia of lower extremities; slough over sacrum; recovery.*—Annie E——, aged thirty-nine, was admitted into Guy's Hospital, March 31st, 1857, under the care of my colleagues, Dr. Hughes and Dr. Wilks (to whom I am indebted for placing the case at my disposal). Both hands were swollen, stiff, and painful, with an erythematous blush over the back of the right, and on the second joint of the thumb of the left. The legs were so far paralysed that she could only very slowly and feebly move them. The muscles were greatly wasted and flabby, but had not lost their excito-contractility by galvanism; sphincters weak; no swelling of the knees or ankles at this time; sensation nearly normal, but at times both legs felt numb, and were drawn up involuntarily; urine acid, high coloured, and scanty; tongue covered with a cream-like fur; skin hot; perspiration profuse, with acid smell; pulse 120; systolic murmur over ventricle. On examining the spine, the lower third of the sacrum was found to be bent forward, the result of a fall eleven years before; and near the sacral notch, on the right side, was the cicatrix of a wound which formed at that time. Except this there was nothing abnormal, nor any pain or tenderness on pressure. The history she gave of her case was that, being a widow, she was necessitated to work laboriously at a mangle. She had for two years, when much exerting herself, felt pain in the back between the shoulders, and a sense of constriction and coldness round the chest. Ten days before coming into the hospital, she was seized with pain in the left leg, and had spasmodic contraction of the muscles, with an increase of the pain and constriction round the chest. She had still power to extend the leg, but could not walk. The day following, the hand, knees, and ankles were swollen and painful. With these symptoms there were febrile heat and diarrhœa. The sphincter ani was so weak that the fæces ran from her involuntarily. On the third day a slough formed over the sacrum. No important change

[4] London and Philadelphia, 1872, pp. 168–172.
[5] I have since met with similar cases.
[6] Reports of the Sanitary Commission.

Digitized by Google

occurred in her symptoms after her admission. There was great muscular emaciation generally; involuntary twitchings of the muscles of the arms and legs; aching, gnawing sensations in both calves; touching the feet gave rise to formication and very lively excito-motor movements. For ten days the hands remained red, painful, stiff, and swollen. She complained much of heat and profuse perspirations, which returned several times in the twenty-four hours. On April 8th the urine was ammoniacal, and contained mucus. The hands were still swollen and erythematous; face flushed; pulse 100, full, as in rheumatism; acid smell of perspiration; respiration 28; movements thoracic and abdominal; abdomen soft; pupils large; nights sleepless. Ordered a grain of opium every six hours, with six ounces of wine daily, and a chop. On April 18th the good effects of the opium and support were very apparent. The patient had passed good nights, and was tranquil in the day. Perspiration lessened. Urine retained in the bladder for thirty-six hours was at length passed voluntarily; it was acid and without mucus. Tongue pale and moist. The slough on the back had deepened. The pupils still continued large. Occasional contraction of the muscles of the legs. No permanent rigidity. Hands remained swollen and stiff, but less red. She was unable to move the shoulders freely. On April 22nd the hands had recovered their normal appearance, and had lost their stiffness; the legs could be moved more freely; the sense of constriction round the chest was gone; pulse 96; skin cool and dry; appetite good; urine normal, but she could not empty the bladder oftener than once in twenty-four hours. From this date she slowly recovered. The opium was continued throughout her convalescence. At the beginning of June the muscles of the lower extremities were galvanised regularly. By the end of the month she was able to stand without help. Her improvement was uninterrupted, and in September she left the hospital quite well.

"*Remarks.*—It is a matter of great clinical interest that lesions of the cord are occasionally attended with an affection of the joints not to be readily distinguished from that which occurs in acute rheumatism. When this happens there may be difficulty in determining the pathology of a case. It may, indeed, be impossible to say whether the symptoms at a certain stage are due to disease of the cord or to a rheumatic state of the blood. In such instances we have a proof of the near relation of humoralism and solidism; for one observer may maintain that the local lesions have a common origin in the altered state of the blood, whilst another may with equal confidence assert their dependence upon a primary disturbance of the nervous centres. The case here recorded is an example of these difficulties. Fatigue from mechanical labour, acting especially on the lumbar and dorsal portions of the spine, in a delicate and anxious subject, appears to have injured the nutriment of the cord; for two years, when much exerting herself, the patient felt pain between the shoulders and a sense of constriction and coldness round the chest. Paraplegia then suddenly came on, followed by redness, pain, and swelling of the larger joints, as in rheumatism; together with these symptoms, there were others indicating a rheumatic condition—white furred tongue, flushed face, hot skin, profuse perspirations having an acid smell, systolic murmur over left ventricle, &c. Was there here a rheumatic state of the blood induced by the spinal lesion, or was the nervous derangement the result of a rheumatic state? Notwithstanding the labours of morbid anatomists and chemical pathologists, we are not at present in possession of any certain knowledge of what constitutes the rheumatic condition. My colleague, Dr. Addison, from his clinical experience, has long drawn attention to the close connexion between spinal lesions and true rheumatism, but has never developed the idea beyond expressing a suspicion of their relation.[8] At the time this case was under care the treatment was a subject of much observation. The result was very satisfactory. Whatever might have been the state of the cord, it was clearly induced by fatigue, and was soon followed by sloughing of the integuments. It would not, therefore, admit of depletory measures, but, on the contrary, required a nutritious diet and wine. Opium was prescribed apparently with great advantage; it allayed nervous irritability, and gave the patient sleep.

"The following case is also illustrative of the relation between spinal injury and rheumatic symptoms. The same plan of treatment as above was equally successful. The therapeutical view of this subject is certainly not without the greatest interest. No doubt the texture of the cord has but feeble reparative powers, notwithstanding it has been shown by experimenters on animals that occasionally, after a transverse section, the parts unite and the functions are re-established.

"CASE 28. *Concussion of the spine; partial paraplegia; redness and swelling of the wrists and ankles as in acute rheumatism. Recovery.*—N. T——, aged thirty-eight, on Jan. 22nd, 1855, inadvertently stepped backwards into a hole a few feet deep and received a concussion of the spine. After a few days he became partially paraplegic, with weak sphincters, and at the same time there came on a diffused redness and swelling of the ankles and wrists. The swelling was not from effusion into the joints, but from œdema of the surrounding tissues. The joints were very painful. The redness and swelling were variable in degree. When most marked they presented the usual appearances of rheumatism, or rather of gout, for the erythema was brighter and the œdema more distinct than in rheumatism. The hands were equally affected with the ankles, though there was no obvious want of muscular power, nor any affection of sensation in the upper extremities. Tongue clear; pulse 120; no acid perspirations; urine high coloured, free from deposits, and of normal quantity. The nerves of the surface generally were hyperæsthetic to a slight touch, but deep pressure gave less inconvenience. The treatment consisted of good nourishment, wine and brandy freely administered, and opium to allay pain and overcome sleeplessness. The pulse gradually acquired more power, and sank to 80. The affection of the joints continued in varying degree through March, April, May, and June. From the beginning of April there was an improvement in the power over the legs. The same treatment was continued throughout without the use of mercurials, local depletion, or counter-irritation. In June the patient was able to walk without assistance. During sleep the hands and feet, wrists and ankles, often became erythematous and swollen. There was occasional formication in the lower extremities. Sleeplessness, from the beginning of the case and throughout, was a troublesome symptom. In July the patient was able to leave the hospital, and to resume to some extent his duties as medical practitioner. He was under the care of my colleague, Mr. Cock."

Again, according to Professor Charcot,[9] "nutritive disorders consecutive on lesions of the nervous centres not infrequently take up their seat in the articulations." He establishes two varieties. The first comprising such cases as those I have already referred to, and including here also the *arthropathy of hemiplegic patients*, first described in 1846 by Scott Alison,[9] afterwards by Brown-Séquard.[10] These "arthropathies are limited to the paralysed limbs, and mostly occupy the upper extremities. They supervene especially after circumscribed cerebral ramollissement, and more rarely as a consequence of intra-encephalic hæmorrhage. They usually form fifteen days or a month after the attack of apoplexy—that is to say, at the moment when the *tardy contracture* that lays hold on the paralysed members appears; but they may also show themselves at a later epoch. The tumefaction, redness, and pain of the joints are sometimes marked enough to recall the corresponding phenomena of acute articular rheumatism. The tendinous sheaths are, indeed, often affected at the same time as the articulations. It is needless to insist upon the interest which pertains to these arthropathies as regards diagnosis, articular rheumatism, whether acute or subacute, being an affection often connected with certain forms of cerebral softening, and one which, indeed, shows itself also occasionally after traumatic causes capable of determining shock in the nervous centres. On the other hand, many affections of the spinal cord are erroneously attributed to a rheumatic diathesis in consequence of the co-existence of these articular symptoms. The clinical characters which render it easy to recognise arthropathies correlated with lesions of the nervous centres, and which allow them to be distinguished from cases of rheumatic arthritis, are chiefly these:—1st. Their limitation to the joints of the paralysed members. 2nd. The generally determinate epoch in which, in cases of sudden hemiplegia, they make their appearance on the morbid scene. 3rd. The coexistence of other trophic troubles of the same order, such as eschars

of rapid formation, and (when the spinal cord is involved) acute muscular atrophy of the paralysed members, cystitis, nephritis, &c. The type of the second group is to be found in progressive locomotor ataxia. ..... Ataxia arthropathy usually occupies the knees, shoulders, and elbows; it may also take up its seat in the hip-joint." Professor Charcot then goes on to describe the physical and clinical characters of this form of arthropathy, and after pointing out the absence of all traumatic or diathetic cause of rheumatism or of gout, he proceeds as follows:—"It is not very rare to find the spinal grey matter affected in locomotor ataxia; but the lesion is then generally found in the posterior cornua. Now, it was quite different in two cases of locomotor ataxia complicated with arthropathy, in which a careful examination of the cord has been made; the anterior cornua were in both cases remarkably wasted and deformed, and a certain number of the great nerve cells, those of the external group especially, had decreased in size, or even disappeared altogether, without leaving any vestiges. The alteration, besides, showed itself exclusively in the anterior cornua corresponding to the side on which the articular lesion was situated. It affected the cervical region in the first case, where the arthropathy occupied the shoulder; it was observed a little above the lumbar region in the second case, which presented an example of arthropathy of the knee. Above and below these points, the grey matter of the anterior cornua appeared to be exempt from alteration. From what precedes, I hope to have made it appear at least highly probable that the inflammatory process, first developed in the posterior columns, by gradually extending to certain regions of the anterior cornua of the grey matter, was able to occasion the development of the articular affection in our two patients. If the results obtained in these two cases are confirmed by new observations, we shall be naturally led to admit that arthritic affections connected with myelitis, and those observed to follow on cerebral softening, are likewise due to the invasion of the same regions of the grey matter of the spinal cord. In cases of brain-softening, the descending sclerosis of one of the lateral columns of the spinal cord might be considered as the starting-point of the diffusion of inflammatory work."

From these illustrations gathered from various authorities, it is, I think, very clearly shown that lesions in the spinal cord or along the course of the motor nerves may give rise to changes in the joints, which in many cases present no difference from the condition seen in subacute rheumatism, in others, as in Charcot's disease, producing rapid disintegration of the bony tissue—decay without repair, as it has been so aptly termed by Morrant Baker. But in all the cases we have changes taking place in the condition of the joints, and these changes produced by causes acting on the nerves connected with the part, either along the course of these nerves or at their origin in the central nervous system.

Now, is there in the phenomena of rheumatism anything suggestive of an irritating cause acting upon portions of the central nervous system? If so, what is it, and how is it produced? Let me call your attention to the changes produced in the system when under the normal state of things the surface of the body is exposed to the action of cold or heat. The effect, as is well known, is very different as regards cold-blooded and warm-blooded animals. External cold diminishes and heat increases the metabolic activity of the cold-blooded animal, acting like a mixture of dead substances in a chemical retort. But in a warm-blooded animal, within certain limits, cold increases and heat diminishes the bodily metabolism, as shown by the increased or diminished consumption of oxygen and production of carbonic acid as the temperature falls or rises. There is obviously a mechanism of some kind counteracting and, indeed, overcoming those more direct effects which alone obtain in cold-blooded animals. But under the influence of urari, which paralyses the end organs of the muscular nerves, a warm-blooded animal behaves, as regards its bodily metabolism, under the influence of external cold and heat like a cold-blooded animal. A similar result is obtained by division of the medulla oblongata. The temperature of an animal so operated upon falls, and then exposure to heat augments and exposure to cold diminishes its metabolic activity. "We can best explain these results by supposing that under normal conditions the muscles which, as we have seen, contribute so largely to the total heat of the body, are placed, by means of their motor nerves and the central nervous system, in some special connexion with the skin, so that a lowering of the temperature of the skin leads to an increase, while a heightening of the temperature leads to a decrease, of the muscular metabolism. Further, though the matter has not been fully worked out, the centre of this thermo-taxic reflex mechanism appears to be placed above the medulla oblongata, possibly in the region of the pons Varolii. When urari is given the reflex chain is broken at its muscular end; when the spinal cord is divided the break is nearer the centre."[11]

How does this bear upon rheumatism? An individual is exposed to a cold draught or gets wet; the surface is chilled; the cutaneous vascular areas are constricted; by reflex action through the vaso-motor system the splanchnic vascular areas and the vessels of the muscular areas are dilated; the vaso-motor nerves distributed to these parts are paralysed, so to speak; with this paralysis of the vaso-motor nerves there is dilatation of the vessels in connexion with them, and so a larger amount of blood is carried to the part, and consequently a larger quantity of oxygen to act upon the tissues. But an increased supply of blood is not sufficient of itself to increase the functional activity of an organ, and therefore to produce increased heat. This has been clearly demonstrated by the well-known experiments on the submaxillary gland and by the experiments on the muscles. The submaxillary gland is supplied by two nerves, the branches of the chorda tympani reaching it along its duct, and by branches of the cervical sympathetic reaching it along its arteries. Now the chorda contains two sets of fibres—(1) secreting fibres acting only on the epithelium cells, and (2) vaso-motor or dilating fibres. Stimulation of this nerve brings about two events—dilatation of the blood-vessels of the gland and a flow of saliva; that is, there is not only a dilatation of the vessels, and so increased supply of blood, but there is an absorption, an assimilation, of some of the molecular constituents of the blood by the gland cells, and if these constituents are properly elaborated by the cells, the formation of saliva. But the elaboration of these constituents can be modified, for by stimulating the sympathetic nerve "a slight increase of flow is seen, but this soon passes off, and so much saliva as is secreted is remarkably viscid, of higher specific gravity, and richer in corpuscles and protoplasmic lumps, and is said to be more active on starch than chorda saliva."[12] This fact has a very important bearing upon the subject I am discussing—namely, the fact that according to the variations in the stimulus applied to the two sets of nerves, alterations in the secretion can be produced; modification, that is to say, in the molecular changes in the contents of the secreting cell can in this way be brought about.

Further, if a small quantity of atropine be injected into the veins, stimulation of the chorda produces no secretion of saliva at all, though the dilatation of the blood-vessels takes place as usual. This proves "that atropine, while it has no effect on the vaso-motor fibres, paralyses the secreting fibres just as it paralyses the inhibitory fibres of the vagus. Hence, when the chorda is stimulated, there pass down the nerve, in addition to impulses affecting the blood-supply, impulses affecting directly the protoplasm of the secreting cells and calling it into action, just as similar impulses call into action the contractility of the protoplasm of a muscular fibre. Indeed, the two things, secreting activity and contracting activity, are quite parallel. We know that when a muscle contracts its blood-vessels dilate; and just as by atropine the secreting action of the gland may be isolated from the vascular dilatation, so by urari muscular contraction may be removed and leave dilatation of the blood-vessels as the only effect of stimulating the muscular nerve."[13]

If this is the case, there must be, in order that heat may be developed, not only an increased supply of blood to a tissue, but also some chemical change in its molecular constituents. Such a molecular transformation is shown by the production of lactic acid and carbonic acid when a muscle contracts or when it dies. The molecules forming these substances are detached from the muscular tissue. Now I would suggest that the change in the molecular constituents of the muscular tissue which leads to the further development of heat results from a weakening or lessening of the power, whatever that may be, which holds the molecules together; that with the dilatation of the vessels in the part, under the influence of the vaso-motor nerves, there is also a splitting up or tumbling to pieces of the

Digitized by Google

albuminoid molecules, and from both causes heat is developed. The normal change of the cyanalcohols is interfered with. Their condensation into higher cyanalcohols with elimination of urea, or their change into cyanamides and amido-acids with the ultimate oxidation of the latter, is modified. The molecules $CH_2\{^{OH}_{CN}$ and $C_2H_4\{^{OH}_{CN}$[14] become detached more or less from each other, and by hydration (by which heat is developed) form substances—glycollic acid and lactic acid—which are readily oxidised, more readily than the amido-acid glycocine which is also formed. The oxygen, though conveyed in larger quantities than normal by the increased blood-supply to the tissue, is completely used up in oxidising into carbonic acid and water the glycollic and lactic acids[11] which have been formed; the excess of lactic acid and the glycocine are unoxidised, and pass into the circulation. Now, in a normal or healthy state of things, the irritating or stimulating cause acting on the vessels and nerves of the skin being removed, reaction would be set up there, the cutaneous vascular area acted upon by the lactic acid would dilate, and consequently the vessels of the muscular area would contract, and this latter contraction would be increased by the stimulating effect of the glycocine or some resulting morbid product, which, being a morbid product, would stimulate some portion of the nervous system. We should naturally expect that under the normal state of things it would so act upon the nervous system as to check the further formation of the morbid material. This could be done by stimulating the vaso-motor nerves connected with the vessels of the muscular area and causing their contraction. We have such an example of stimulation, though in a different direction, in the effect of carbonic acid on the respiratory centre. A closer illustration may perhaps be found in what results from the injection of bile (which contains glycocine) into the blood. This is at once followed by increased arterial tension. But the closest analogy may be found in the effects produced on the system by what is simply a form of vegetable uric acid—viz., caffeine. In moderate doses, this increases the heart's action, both by its direct effect on the organ and also by exciting contraction of the arteries; the blood-pressure and the frequency of the pulse are both intensified. The morbid product, then, which, as I shall endeavour to show, is uric acid, by increasing the arterial contraction, would, in a healthy state of things, cause less blood to go the muscular area, the molecular constituents would again be held more firmly together and undergo the normal changes, the uric acid being meanwhile excreted by the kidneys and the lactic acid by the skin. I have here drawn you a picture of an ordinary feverish cold—the primary chill, the ensuing febrile condition, the elimination of lithates, with the subsidence of the attack.

The morbid product I have said is uric acid and results from the excessive formation of glycocine in the muscular tissue. This brings me to the questions—What relationship has glycocine to uric acid, and how are these concerned in the phenomena of rheumatism? We know that in gout an abnormal amount of uric acid is present in the blood. The researches of Dr. Garrod have shown this very clearly. But how the uric acid is formed, why in some cases it leads to uric acid calculi, why in others it passes off in the urine as gravel, in others as urate of ammonia, and in all these cases, it may be, without the joints being disturbed; why, again, in other cases associated with uric acid in the blood, the joints become affected and present the symptoms known as gouty, are points still open for discussion, and I will, therefore, as I think they are closely related to and have a distinct bearing upon the phenomena of rheumatism, turn aside and detain you for a short time whilst I try to throw some light upon them.

(To be concluded.)

MEDICAL HEROISM IN RUSSIA.—The two Russian doctors who, as mentioned in a recent issue, heroically attended to a very violent hydrophobic patient, are now in the Kharkoff provincial hospital under the care of Professor Kovalevski. They are about to be sent to Pasteur in Paris, a considerable sum having been already received in subscriptions for the purpose of defraying the expense.

Gulstonian Lectures

ON

SPASM IN CHRONIC NERVE DISEASE.

Delivered at the Royal College of Physicians of London, March, 1886.

BY SEYMOUR J. SHARKEY, M.B., F.R.C.P.,

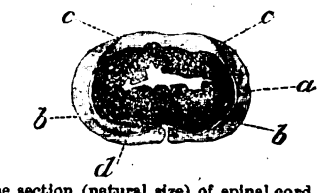
ASSISTANT-PHYSICIAN AND JOINT-LECTURER ON PATHOLOGY AT ST. THOMAS'S HOSPITAL.

LECTURE II.

(Concluded from page 626.)

THE case I shall relate next is a good instance of the results of pressure on the cord applied from within by central tumours. The disease is a very rare one, and the specimen I show is so beautiful an example of it that I have endeavoured to work out the histological changes which it has produced in the cord as minutely as possible, in order to see how far they explain the clinical phenomena observed during life.

C. W——, aged fifty, waiter, was admitted into St. Thomas's Hospital, under the care of Dr. Stone, on Jan. 24th, 1885, and died on March 18th, 1885. His family history was unimportant; he had a wife and five children, all strong and well. He had enjoyed the best of health since he was a child, and had never had syphilis. His illness commenced somewhat suddenly, with pain in the back, eighteen months before his admission. Partial loss of power and sensation in both his arms and hands soon followed, together with tremulousness on attempting to use them. It was not until three months before coming to the hospital that his legs became affected. Since then he had had numbness and pricking sensations, loss of power, and a sensation of coldness in them. On walking, the ground felt soft. His bowels had been irregular, and he had had some difficulty in passing urine; his appetite had been poor; he slept fairly well. On admission, he was a healthy-looking man, and complained of loss of power, numbness, and formication in his legs, together with incontinence of urine. On examination, no angular curvature or marked rigidity of the spine was discovered; but some tenderness without prominence was found about the lower cervical and upper dorsal vertebræ. The legs were almost completely paralysed and anæsthetic, but there was no wasting of muscles, no rigidity, and no tremors. The tendon reflexes were much exaggerated and there was ankle-clonus in both legs. The patient could use his hand and arms fairly well, but they were numb and tremulous and the grasp was weak. There was no ocular paralysis. Urine was retained and the bowels confined. Pulse 84; temperature normal. Tongue slightly furred. The urine was of specific gravity 1030; no albumen; faintly acid. The abdomen was natural; hepatic and splenic dulness was normal. The lungs were resonant and the breathing healthy, nor was there anything abnormal detected on examination of the heart. He continued in much the same condition for some weeks, complaining a good deal of pain in the back high up and of occasional pains in the legs. The muscular power and sensation underwent but slight variations in the upper and lower extremities, though he complained sometimes of twitchings. The temperature was generally normal, but now and then somewhat raised. Incontinence of urine set in about Feb. 5th, and it became alkaline and phosphatic, and contained albumen. On Feb. 24th it was noticed that there was tenderness in the lower dorsal and lumbar regions of the spine, and that complete anæsthesia existed below the level of the middle of the chest. On March 12th the legs were completely powerless and the right leg œdematous. The patellar and plantar reflexes were very brisk; ankle-clonus was marked, but there was no knee-clonus. Sensation of touch and of pain in lower extremities was abolished; sensation of heat was retained. There was no control over the bladder or rectum. In the centre of the sacral region was a large horseshoe-shaped bedsore, with a red granulating surface, and a smaller one was forming over the right hip. The urine was alkaline, and contained pus and mucus. On March 14th the patient took his tea at 5 P.M., and seemed to be in his usual condition. Soon after 6 P.M., when the sister



Digitized by Google

came to him, he was found to be unconscious. At 6 P.M. his eyes were shut and he was breathing heavily, and when asked how he was, he said he was "as usual." The pupils acted to light. His tongue was protruded to the left, his left cheek was flaccid, and his left arm powerless. His head and eyes were turned to the right. The pulse and heart-sounds were very feeble, but there was no murmur. He altered but little after this, and died on March 18th.

The following is an account of the post-mortem examination, made twelve hours after death:—Body emaciated. Over the sacral region in the middle line a large superficial bedsore was seen, and there were several smaller ones in the neighbourhood. The peritoneum, pericardium, and right pleura were healthy; the left pleura was everywhere firmly adherent to the thoracic wall. The lungs were intensely congested and œdematous, but otherwise healthy. The heart appeared normal in size. The valves on the right side were natural; those on the left a little thickened, but competent. Along the line of attachment of the mitral valve to the wall of the heart on its auricular aspect was a series of papilliform elevations, such as are often found in this position in cases of endocarditis. There appeared to be little or no coagulum upon their surface. The spleen was large, weighing 9½ oz., and contained several large pyramidal infarcts, which were still soft, and had a very clearly defined white margin. The bladder, ureters, and the pelves of the kidneys were inflamed, and presented some phosphatic deposits upon their surface. The kidneys were somewhat large, succulent, and showed evidence of early suppurative nephritis. The capsule peeled off easily, and below it were seen, in large numbers, minute white dots, which felt gritty when touched with the point of the knife. In one kidney was a small infarct, opaque, yellowish white in colour, with a red margin. The weight of the kidneys was 10¼ oz. The liver was somewhat large, and very heavy, weighing 70½ oz. The pyloric end of the stomach was attached by slight adhesions to the gall-bladder. The latter was completely filled by a large gall-stone. Its walls appeared to be fairly healthy, except at the extreme fundus. The latter was thickened by new growth, and projected as a hard nodule in the small indentation through which the healthy gall-bladder often projects on the upper surface of the liver. From the nodulated fundus, as a centre, grew a large mass of carcinoma into the substance of the right lobe of the liver. The line which limited its growth furthest away from the gall-bladder was curved, and in its neighbourhood the luxuriant new growth bulged upon the surface of the organ. That portion which was nearest to the gall-bladder was depressed and harder, giving one the impression that it was older than the peripheral growth. Large vessels coursed over the surface of the mass. One or two very minute islands of new growth were seen here and there in the liver-substance at a distance. The stomach and intestines were healthy, and no focus of new growth was found which could have given rise to that in the liver as a secondary product. The spinal column, as seen from the interior of the body, seemed to be perfectly natural; nor, on removing the posterior portion of it and taking away the spinal cord, did it present any traces of disease. On removing the brain, the greater bulk of the right hemisphere, as compared with the left, was very striking; to the finger it felt soft, especially in the lower part of the parietal region and in the temporo-sphenoidal lobe. On making a horizontal section, so as to expose all the central ganglia to view, it was seen that the whole of the corpus striatum—both the nucleus caudatus and nucleus lenticularis—was softened, and broke up under a stream of water. The internal and external capsules, the convolutions of the island of Reil, and other convolutions adjacent to them, were in a similar condition. The right middle cerebral artery was found to be completely blocked, just beyond the spot where the first few vessels are given off to the central ganglia. On examination of the spinal cord, it was found that the dura mater was healthy. At the junction of the lower dorsal and upper lumbar regions was a softened area about an inch in length, and involving apparently the whole thickness of the cord. It was rather deep red in colour, with a pale yellowish island at one spot, which, with its deeper coloured periphery, was very suggestive of infarction as it is seen in other organs. Higher up, about the middle of the dorsal region, the anterior spinal artery was interrupted in its course, and surrounded by a long superficial hæmorrhage of a brownish-red colour. The cervical enlargement, especially in its upper part, seemed to be of enormous dimensions, retaining, nevertheless, the natural shape of the cord. On pressing with the finger, it was found to be very firm over an area one to two inches in length. On making a transverse section through the cord in the upper cervical region, where there was no feeling of increased density, the central canal was found to be much enlarged and to contain blood partially coagulated. Where the canal opened out into the fourth ventricle it appeared to be healthy. When a section was made through the enlarged and hardened portion of the cord a most curious appearance presented itself. A very narrow and even rim of apparently healthy white matter surrounded, as with a sheath, a dense reddish-grey mass, of oval outline. In the centre of this mass was a hollow space, which presented a very marked resemblance in shape to the central grey matter of the spinal cord, and which contained blood. On teasing out a portion of this new growth in the fresh state, it was found to consist mainly of spindle-cells and of cells with many long fine processes, such as one sees in gliomata.

In the first of these two cases of spinal tumour, where the pressure was exerted upon the cord from without, death occurred in twelve months from the appearance of the first symptoms. The latter were, in order of time, weakness of the legs in walking, increasing weakness of legs, accompanied by cramp and shooting pains, paraplegia, cramp, and involuntary flexing of legs; slight numbness and long continued attacks of muscular spasm in the lower extremities; and, finally, persistent rigidity. In the second case, the symptoms due to pressure alone, which was exerted upon the cord from within in the cervical region, continued for fifteen months uncomplicated by other disease; they were simply partial loss of power and sensation in the arms and hands, and some tremor in them when used. This was the condition of the arms when the patient was admitted into

FIG. 24.

the hospital, and it was little altered even at the time of his death, which occurred twenty months after the appearance of the first symptoms. During the last five months of life, fresh symptoms arose in relation with hæmorrhage and softening in the dorsal region of the cord—accidents which are very liable to occur in cases of gliomata; and the accident which finally proved fatal was embolism of the right middle cerebral artery, giving rise to left hemiplegia.

When a tumour grows in the spinal canal outside the cord, it may produce but few symptoms until it presses the cord against the resisting walls of the canal; but after this has taken place the course of the disease is naturally very rapid, as the cord is quickly flattened by the constantly increasing demands for growing space which are made by the tumour. When a tumour arises, on the other hand, within the spinal cord, it disturbs its functions even from the very commencement; but as the nerve substance appears to be elastic, and to allow a good deal of gradual stretching without serious interference with its functions, a tumour may go on growing for a long time before it produces striking pathological phenomena, either by pushing the cord against the bony walls of the spinal canal, or by exhausting the elasticity of the membranes which envelop it. These remarks apply only to gliomata and such non-malignant tumours as exert pressure on surrounding tissues, but do not invade them. The description which I now give of the microscopic appearances of the spinal cord and of the tumour in the present case shows that a state of things is produced by the disease which fully explains the chronicity of some of these cases, and the trivial symptoms which present themselves. The tumour is situated almost entirely in the cervical region, and mainly in the cervical enlargement. In the middle of the latter the mass assumes its largest proportions, and the enveloping sheath of nerve-tissue is comparatively smaller than in any other region of the cord (Fig. 24). When examined with the

Digitized by Google

microscope, the greater part both of the white and of the grey matter can be readily recognised, though pressure has produced some alterations in them. On holding up a stained transverse section to the light, one observes in its anterior third a small oval area which is more transparent than the parts around; it is situated in the white rim, and lies upon the tumour. Under a low power this proves to be the anterior cornu, containing the usual multipolar cells (Fig. 26). Symmetrically placed upon the opposite side of the tumour is a similar oval mass, which is the other anterior cornu. The cells are not healthy on either side, but are pigmented, and more or less elongated by pressure (Fig. 28); but considering the pathological conditions to which they have been subjected, they are singularly well preserved. The anterior roots can be traced from the cornua through the white substance to the periphery of the cord, and the posterior cornua extend backwards along the margin of the tumour. The lateral, posterior, and anterior columns of white fibres are all present, and show but slight pathological alterations (Fig. 27); there is no marked sclerosis anywhere. The same may be said of the whole extent of the cord which is occupied by the main bulk of the tumour. The latter becomes smaller and smaller in the lower cervical region, and is no longer evident as a mass in the lower dorsal region. Here, however, considerable hæmorrhage and softening have occurred (Fig. 25); and to these changes the later symptoms in the case may be referred, when the legs became paralysed and increase of the tendon reflexes and ankle-clonus appeared. As the tumour becomes smaller, and finally ceases to be recognised as such in the dorsal region, it is probable that the changes present in the cord there represent the early stages of its growth. They occupy the left half of the posterior columns and the left lateral column, and consist of a peculiar thickening of the neuroglia, which is transformed into a hyaline substance (Fig. 37). The nerve fibres in its meshes are at first but little altered, then they become swollen; the vessels are much thickened, and their walls assume the same glassy appearance as the neuroglia. In the cervical region the central canal cannot be recognised, but in the lower parts of the cord, where the growth is early, it can be seen pushed to the right. As to the tumour itself, it consists of numbers of islands of new growth situated around large bloodvessels as centres, and starting from them. The vessels have the thickened hyaline walls already referred to, and numbers of fibrillæ can be seen issuing from them. The new growth is richly nucleated, and has a very definite radiate arrangement round each centre. On examining very fine sections under high powers, the new tissue is seen to consist of meshworks of very delicate fibrils and bundles of fibrils in which are situated the nuclei. It may therefore be put down as glioma. (Figs. 29 and 30.) In Virchow's *Archiv* for 1884 a very similar case is recorded by Dr. Reisinger, and an abstract of all the cases to be found in medical literature is added. They amount to twenty in all. It is very curious that in Dr. Reisinger's case the earliest changes were seen, as in mine, in the posterior columns near the central canal. The minute anatomy of the specimen I show here explains why the symptoms in cases of central tumour of the cord may be so slight and extend over such long periods of time, and why spastic conditions are not readily induced, as they are when pressure is applied from without. For even when the disease is so extreme that the substance of the cord forms merely a narrow ring round it, the nerve tissue presents very slight pathological changes.

I shall now relate a case which illustrates the modification which occurs in the symptoms of disease of the lateral columns, when it is combined with disease of other parts of the cord.

Case of Primary Disease of the Lateral Columns, accompanied by similar changes in other parts of the Central Nervous System.—M. H——, aged fifty-three, whose occupation was pulling down old houses, was admitted into St. Thomas's Hospital, under the care of Dr. Ord, on Nov. 10th, 1884, and died on Dec. 2nd of the same year. There was no history of nerve disease in his family. He had always enjoyed fair health, though troubled with indigestion and bilious attacks. The only definite illness he had had was ague at the age of twenty-three. He had never had syphilis. Before his present illness began he had been in the habit of drinking five or six pints of beer daily, but no spirits; he also smoked a good deal—about half an ounce of tobacco a day. His occupation necessitated pretty constant exposure to cold and wet, and he had had several falls, but had never had any symptoms of importance after them. About seven years before admission to St. Thomas's he had had great anxiety about money matters, and was up night and day for about a month. He then got out of sorts, and presently noticed that the toes of both feet were becoming numb, and the legs somewhat stiff; this, together with weakness, produced difficulty in walking, and the right leg began to drag. He was quite unable to walk in the dark or with his eyes shut, or to turn round quickly. The difficulty in walking had steadily increased, and both legs had become equally affected. Six months ago, total inability to get about made him take to his bed, the numbness increased, and he began to be troubled with jerking of the legs; the arms also got somewhat stiff. He noticed that, although he could grasp large objects well, he could not pick up small ones, such as pins. He had burning pains in the legs and shoulders, and shooting pains in the back and abdomen. During his whole illness he had suffered from indigestion and constipation; his legs had become thinner, and he had lost weight. His sight, which used to be very good, had gradually become dim, so that he could only read print when it was held very close to him. His hearing had remained good. The right foot and ankle had been swollen for a short time previously, but none of his other joints had been affected. He had lost all sexual desire, and for five years had had some trouble with his urine, sometimes having retention, at others continuous dribbling. He had never had any difficulty in speaking or in swallowing. On admission the patient was an emaciated man, complaining of inability to walk, dimness of sight, and shooting pains in the legs and thighs. Although unable to stand, he moved his legs freely in bed, and there appeared to be no loss of power in them, but there was some rigidity. The arms showed no loss of power; the grasp was strong with both hands, but there were slight tremors in the right arm when he used it. The muscles of the face were stiff and tremulous when strongly contracted. There was partial loss of control over the bladder, but none over the rectum. Sensation was impaired in the lower extremities, but not markedly; the patellar reflex was absent, and there was no ankle- or knee-clonus. Plantar reflex was brisk on both sides, the cremasteric absent. The lower abdominal reflex was slight on both sides, the epigastric absent. The right pupil was larger than the left, and both acted to light and to accommodation. There was no oculo-motor paralysis or colour-blindness. He had slight lateral nystagmus. There was well-marked atrophy of both discs, most marked on the inner side. There was no affection of speech or of hearing, but the sense of smell was much impaired. The radial vessels were somewhat thickened; the bowels constipated. The abdominal and thoracic viscera were free from serious disease. The urine had a specific gravity of 1025, was alkaline, and contained phosphates, but no albumen. During the rest of his life little alteration occurred in the symptoms which have been described, but cystitis with high temperature set in. He was also attacked with swelling, redness, and œdema of the metatarso-phalangeal joints on both sides and of the ankle-joints; he finally got bedsores, and died on December 2nd. The necropsy made next day showed the body to be that of a well-nourished, grey-haired old man. The legs were thin, and proportionately thinner than the arms. Both heels were black, as if from commencing gangrene. The external malleolus on the left side, as well as the sacrum, was in a similar condition. The ankle- and knee-joints were quite healthy. The heart, lungs, liver, and spleen presented no evidences of disease. The kidneys were healthy, but the bladder was evidently inflamed, as it contained three or four ounces of flaky purulent fluid, and its mucous membrane was of a deep purple colour. The intestines, pancreas, and suprarenals were all free from disease. The sheath of the spinal cord was distended with clear fluid, so that when the latter escaped the cord was seen to occupy but a small part of the tube formed by the dura mater. There was no undue vascularity, nor anything remarkable on external examination. On making transverse sections of the cord from below upwards, it was found that in the lower part of the lumbar region there were no abnormal appearances. But in the upper lumbar region three tracts of degeneration were visible. Two of them were in the lateral columns, which were symmetrically affected; the third consisted of the columns of Goll, which together formed a triangular area. The diseased parts were transparent, and had the colour of glue. The degeneration

Digitized by Google

could be followed in all three tracts as far as the medulla oblongata, but there it became less and less evident, and could not be seen at all in the upper part of the medulla and pons Varolii. The disease in the lateral columns appeared to be superficially situated, and was more extensive in the upper than in the lower regions of the cord. It occupied a larger area on the surface of the lateral columns, but penetrated less deeply into them than is usually the case in descending degenerations. It was impossible to say from a naked-eye inspection whether the columns of Goll were the only parts of the posterior columns which were diseased, or whether the degeneration affected those of Burdach as well. The cord was firm, and, with the exception of the regions already referred to, it appeared to be healthy. The only morbid appearances discovered in the brain were found in the optic nerves. They were both pale and flattened, and evidently the seat of degeneration. The corpora geniculata, corpora quadrigemina, optic thalami, and supposed cortical centres of vision were all normal in appearance. There were symmetrical ivory exostoses on the fourth and fifth ribs on each side in the posterior third of their length, but they were not so situated that they could press upon either nerves or vessels.

The symptoms in this case which point to lateral sclerosis are weakness of the limbs, tremulousness, jerkings, and rigidity; while numbness, pains, loss of sexual desire, difficulty with the evacuations, dimness of sight, and absence of the patellar reflex indicate more extensive disease. On microscopical examination the spinal cord proves to be the seat of very widespread changes; and yet the parts affected are so constant throughout that the affection cannot be looked upon as an indiscriminate one, but must be placed among the more complicated combined system diseases. It will be seen by reference to Fig. 33 that the regions affected are (1) the lateral columns; (2) the posterior columns; (3) the direct pyramidal tracts; (4) the anterior root zones; and (5) in a minor degree the grey matter of the anterior cornu. But it will also be observed that in the neighbourhood of the grey matter everywhere a zone remains healthy, and, in addition, a superficial tract of fibres situated between the crossed pyramidal and cerebellar tracts posteriorly, and the anterior root zones anteriorly, is unaltered. The pathological changes throughout the diseased areæ are the same, and must be considered to be those of chronic inflammation affecting mainly the nerve fibres, and in a far less degree the neuroglia; in other words, they represent a form of chronic myelitis. In the regions referred to are seen increase in the nuclei of the neuroglia, and in the white corpuscles within the vessels, hyaline swelling of the neuroglia, distension of the neurilemma, and disintegration of the white substance of Schwann (Figs. 34, 35, 36). Motor phenomena were those which were most strikingly affected during life, and sensory changes were far less marked. The pyramidal tracts, direct and crossed, and the anterior root zones, are undoubtedly motor regions; while the columns of Goll are afferent, and connect centres below with centres higher up; hence the disease is principally an affection of the motor systems of fibres. The escape of the small superficial area in the lateral column from pathological changes is exceedingly interesting, and marks it out as a tract containing some particular set of nerves. Gowers first called attention to this small tract of fibres, which appear to be afferent, and to degenerate centripetally. Several other writers have also mentioned it, among them Dr. Hadden, and Dr. Howard Tooth has a paper on it in St. Bartholomew's Hospital Reports for 1885, vol. xxi. The medulla oblongata, pons Varolii, crura cerebri, motor convolutions, anterior crural and optic nerves, and the triceps femoris muscle were all examined microscopically. The optic nerves were found to be atrophied, and there was an excess of nuclei in the anterior crural nerve and in the triceps femoris; but with these exceptions all the parts examined were free from disease.

I have detailed this case, rather than one of the more usual ones, where chronic affections are confined to less extensive systems of nerve fibres, in order to show that disease is a very complex process, however much we may endeavour to simplify our notions of it, and likewise to point out in how modified a form disease of the pyramidal tracts presents itself, if there be in addition pathological changes in other regions of the cord.

Before leaving the subject which I have thus far been illustrating—namely, the relation between diseases of the cerebral motor system and the production of chronic muscular spasm,—a few words must be added in answer to the question, Does spasm ever result from afferent stimuli reflected on to efferent fibres in the cerebral centres, or from diseases of the commissures? If we limit the term cerebral centres to the grey matter of the hemispheres and central ganglia, I know of no undoubted instances of reflex spasm in connexion with them. Convulsions, which may be due to such causes, do not come within the scope of the present lectures; and had I the time to treat of them, I should shrink from casting a shadow upon ground which has been so brilliantly illuminated by the genius of Hughlings Jackson. Several cases of tumours of the corpus callosum have come under my notice, and they have been published by Dr. Bristowe in *Brain* (vol. vii.) I cannot do better than quote the words of so distinguished a physician and pathologist in describing the symptoms which were observed in them. The chief characteristic features were: "1. Their ingravescent character, a character which they possessed in common with other cases of cerebral tumour. 2. The gradual coming on of hemiplegia, for the most part resembling in its distribution the paralytic symptoms usually attending hæmorrhage into one of the hemispheres, or softening due to embolism. 3. The association with the paralysis of one side of vague hemiplegic symptoms of the other. 4. The supervention of stupidity, associated for the most part with extreme drowsiness, a puzzled inquiring look when awake, a difficulty of getting food down the throat, and cessation of speech. 5. The absence of implication of the oculo-motor nerves, and of direct implication of other cerebral nerves; and, lastly, death by coma." From beginning to end of these cases no muscular spasm occurred.

In the remarks which the time at my disposal has allowed me to make on diseases of the pyramidal tract, and the part played by it in the production of spasm, I have tried to point out how numerous and varied the clinical phenomena may be, according to the level at which the pathological conditions occur, according to the method of attack—whether from within or from without,—and according to the presence or absence of disease of other portions of the central nervous system. I must now leave this division of my subject, and pass on in the last lecture to a consideration of the spinal motor system, and to so-called functional spasm.

ON A

BACILLUS CULTIVATED FROM THE BLOOD AND FROM THE DISEASED TISSUES IN SYPHILIS.

BY F. S. EVE AND A. LINGARD.

THE course of syphilis and the structure of the new formations indicate a probability amounting to a conviction that the disease is produced by a micro-organism, which gains access to the body by the primary inoculation, and is carried through the lymphatic system into the blood. We have, as opportunity permitted, continued to investigate the question of the etiology of syphilis since 1884, when one of us (Mr. Eve) showed bacilli in primary sore, indurated lymphatic gland, and secretion from sores, at a lecture on the Histology of Syphilis given at the Royal College of Surgeons. We have, as our methods improved, with increasing constancy demonstrated bacilli in numbers in many (at least twelve) primary sores, in indurated glands from three cases, in gummata from two cases, in a papular syphilide, and in condyloma. After many attempts we have latterly succeeded in that which has hitherto not been accomplished—namely, in cultivating a morphologically identical bacillus from the blood of syphilitic patients in two instances, and from syphilitic tissues in three instances. We offer brief details of the following observations in which positive results were obtained.

1. A pure cultivation grew after inoculation, under stringent precautions, of solidified blood-serum with blood from the lobe of the ear of a patient in the Lock Hospital, who had a profuse tuberculo-squamous syphilide. An indurated sore had existed two months, but he had taken no mercury. 2. Cultivation from the blood of a young man, an out-patient at the London Hospital, who had a general well-marked roseola, which had recently appeared. He had only taken

Digitized by Google

mercury three weeks. 3. A patient in the Lock Hospital was suffering with a hard sore, a bubo, and a general tubercular syphilide. He had taken no mercury. With his consent a papule with the subjacent cutis was excised with scissors from the front of the thorax, the skin being previously cleansed with a solution of carbolic acid (1 in 20), and the scissors heated immediately before use. A blood-serum tube was at once inoculated from the lymph exuding from the base of the papule, and in the course of a few days a cultivation similar to the preceding developed. On subsequent examination sections of the papule showed very numerous bacilli scattered in the connective tissue interspaces of the corium and around and within the small aggregations of round cells, which in parts invested the capillaries. Many of the bacilli showed the unequal staining to be presently described; others were uniformly stained (see Fig. 1). 4. A similar organism was also obtained in a cultivation from a much enlarged and distinctly indurated lymphatic gland from a man who had an indurated but somewhat ulcerated sore in the furrow

FIG. 1.

Bacilli in sections of a syphilitic papule. The three pale bacilli were unstained, and are possibly bacilli containing spores (950 diameters).

FIG. 2.

Cultivation from blood (950 diameters).

around the glans penis. The sore and the glans were excised at the same time, and in both bacilli were demonstrated. The sore had existed for one month. He left the hospital shortly after the operation and was subsequently lost sight of. The condition of the glands, the histological characters of the sore, and the history of the case, were all in favour of the view that he had syphilis. 5. Cultivation from lymph exuding from the base of a somewhat inflamed sore on the inner surface of the prepuce, which was removed by circumcision. There were distinctly indurated glands in both groins, and the patient subsequently developed secondary manifestations. 6. An impure cultivation grew after inoculation with lymph from the base of a freshly excised condyloma.

In none of the cases from which cultivations were obtained had mercury been administered for any length of time, and a long series of failures have led us to reject entirely cases which have been long under mercurial treatment. All these cultivations were composed of a very peculiar and somewhat polymorphous micro-organism (see Fig. 2), consisting of longer or shorter rod-like bodies, with rounded, and

FIG. 3.

Bacilli in section of a chancre (950 diameters).

FIG. 4.

Cultivation of bacilli from a phagedænic sore (950 diameters).

sometimes enlarged, or distinctly club-shaped ends; they were usually straight, but occasionally curved. The longer bacilli were as a rule unequally stained, and showed from three to five, or even eight, deeply stained segments united by unstained protoplasm and enclosed in a hyaline sheath. Organisms were observed in which the unstained material was drawn out in a thread-like filament connecting the enlarged end to the rest of the bacillus. The shorter organisms were composed of two elongated or oval masses of stained protoplasm separated by a clear interval, which relatively increased as the bacillus became longer. The transitional forms from these to the long beaded bacilli were patent to the observer. If the specimens after staining were not well washed, the organisms were uniformly coloured, or the beading was indistinct; hence in sections this peculiar characteristic could not be so clearly brought out; but it is well shown in Fig. 3, which was taken from a chancre in an undoubted case of syphilis. Many of the bacilli in sections of this sore were uniformly stained, or showed a clear median space such as may be seen in the short and in the uniformly stained bacilli in Figs. 1 and 2. Other slight shades of difference may be explained by the varying conditions under which the organisms grow in culture media and in the various textures of the body. The bacilli in the case above referred to existed in great abundance, either singly or in groups, in the connective tissue interspaces around and at the base of the sore; they were less numerous in the granulation tissue, a fact which may be explained by the observations of Ribbert on the resisting power of leucocytes to the growth of micro-organisms. This was their usual mode of distribution in chancres, but they were in many instances observed in lymph capillaries and within large clear cells. In lymphatic glands the bacilli were most abundant within and in the tissues adjoining the peripheral lymph channels, and were observed also in lymph cells. In sections of condyloma they were numerous in the connective tissue interspaces of the corium, still more so throughout the epithelium, and formed colonies on the surface. In gummata they were most numerous at the margins, where the disease was extending. In a case of phagedænic sore, a cultivation (see Fig. 4) closely resembling that above described was obtained from the ichor flowing from its surface, and later from the lymph flowing from the base of the sore after its free excision. Induration of the inguinal glands on both sides subsequently appeared, and syphilis was diagnosed. The general features and the staining reaction of this bacillus were the same as in that found in ordinary cases of syphilis, but the segmentation or beading was not so well marked. The cultivations obtained from syphilitic patients appeared as a thin, faintly yellow or brownish yellow, uniform, or slightly tuberculated layer on the surface of the media. The organism grew in solidified blood-serum, which it did not liquefy, and less readily in solidified hydrocele fluid and agar-agar. As regards its differentiation from the bacillus described by Alvarez and Tavel, as existing in normal smegma, we find that, in contradistinction to the latter, the bacillus here described is, after staining with fuchsin, decolourised by dilute nitric acid. Decolourisation occurs both in cultivations and in sections, and is also accomplished by oxalic acid. We have studied the bacillus of normal smegma both in scrapings and by cultivations, and are unable to identify it with that which we have found in syphilis. Nor does it seem in the least degree probable that in syphilis a non-pathogenic organism should be found in all the lesions, even in the internal organs. In sections known to be crowded with bacilli uniformly negative results have followed the use of Lustgarten's method. Our best preparations have been obtained by staining with a solution of Humbolt red in aniline oil and spirit, and decolourisation with spirit. The bacilli can also be demonstrated, but less satisfactorily, by Gram's method, and still less so by Weigert's solution of gentian violet. The inoculation of monkeys with our cultivations has so far been unsuccessful in inducing syphilis, but so has also inoculation with portions of chancres and of phagedænic sores. Nevertheless, the cultivation of a morphologically peculiar bacillus in two instances from the blood of syphilitics and from some of the chief lesions, and its recognition in the diseased tissues, have from analogy a striking significance in regard to the etiology of syphilis, and lead us to hope that by the continuation of our investigation we may yet experimentally prove that the organism described is the cause or the carrier of the disease. Owing to the attention which this question is now exciting in Germany we considered it necessary to publish this preliminary notice of our results.

A NOTE ON CYCLIC ALBUMINURIA.

BY WILLIAM COLLIER, M.A., M.D.,
PHYSICIAN TO THE RADCLIFFE INFIRMARY.

THE following case may prove of interest in connexion with Dr. Pavy's recent paper, reported in THE LANCET of March 6th, on Cyclic Albuminuria.

I was recently called to an undergraduate who was suffering from epistaxis. In answer to inquiries I learnt that for some years he had had at intervals similar attacks, which as a rule proved difficult to stop, though bleeding from other parts of the body, the result of cuts, or after the extraction of teeth, was easily controlled. The last attack of epistaxis occurred twelve months previously. He also

Digitized by Google

mentioned that a brother and sister were at times troubled with epistaxis. The bleeding was on this occasion easily controlled by the use of alum. Two days later I was again sent for, and informed that the bleeding had returned early in the day and had been very troublesome. On asking for a little of his urine, the patient at once volunteered the following information. Three years ago, when at Rugby School, after getting a chill, albumen was found in his urine. Twelve months ago, when thinking of becoming a candidate for the Indian Civil Service, he underwent a medical examination, and was warned that he would probably be refused, as his urine contained albumen. In consequence of this advice he gave up the idea. Since the first appearance of albumen three years ago his general health had been good and he had led a very active life, having on two occasions run in the Rugby-Crick (the annual long-distance cross-country steeplechase), and had gone in for long-distance running at Oxford. His condition was as follows:—Complexion pale; tongue clean; pulse slow and resisting. Heart: slight accentuation of second sound; no evidence of hypertrophy. Lungs healthy. Urine passed at the time of my visit (about 5 P.M.) was acid, sp. gr. 1030, contained a large quantity of lithates, and with the nitric acid tests showed about one-eighth albumen. I requested him, as is my invariable custom, in accordance with Dr. George Johnson's teaching, to send me a specimen of urine passed the following morning immediately on rising. On testing this with the ordinary nitric acid tests I could find not the slightest trace of albumen, though the tests were carefully repeated several times. Another specimen, passed about 1 P.M. on the same day, contained about one-eighth albumen. The microscope showed the presence of amorphous urates, but no casts could be found. As the patient was feeling very ill, and had been for the past few days much troubled with headache, I advised him to return home. He left Oxford the same afternoon, and I have not as yet heard from him.

The case is very incomplete, and as I had only one opportunity of testing the morning urine, I should not have reported it had it not seemed to me to suggest that possibly some of the cases remarked on by Dr. Pavy may at the end of another year or two develop all the usual symptoms of chronic Bright's disease. I cannot doubt that, in spite of the patient's apparently sound health until within the last week or two, the headache, epistaxis, high-tensioned pulse, slightly accentuated second sound of heart, and albuminous urine from which he suffered, were all secondary to slow changes in the kidneys, the result of the chill taken when at Rugby three years previously. Nor is it improbable that had I had frequent opportunities of examining his early morning urine, I should have found in such specimens, as in my former examination, an absence, or at the most a very faint trace, of albumen. On referring to my notes of the clinical lectures given by Dr. George Johnson while I was a student at King's College Hospital, I find the following remarks in a lecture delivered June, 1879, on Practical Matters connected with Bright's Disease:—"Remember, also, to test urine both after food and exercise, as it frequently happens that scarcely a trace appears in the urine voided before breakfast, while a large quantity may be present in that passed an hour or two after. *Exercise* may cause the presence of albumen when the urine is unaffected by food." In proof of this Dr. Johnson related the case of a medical man suffering from chronic Bright's disease who found albumen after exercise, but never after food if he *rested*. While house-physician to the Wolverhampton Hospital, in which district cases of acute and chronic Bright's disease are very common among the stokers and hammerers at the various ironworks, I had ample opportunity of testing the value of Dr. Johnson's teaching, and can recall more than one case in which the urine was most markedly influenced by rest, containing only the slightest traces in the early morning, but considerable quantities in the middle of the day. Such facts would suggest the danger of disregarding the continued presence of albumen in the urine at certain periods in the day, in spite of the absence of symptoms—unless, at any rate, it had existed a considerable number of years.

SWANSEA HOSPITAL.—The secretary of the hospital has received, from an anonymous donor, a cheque for £600 towards the funds of the charity. Upwards of £3000 have been received in a similar way during the past few years.

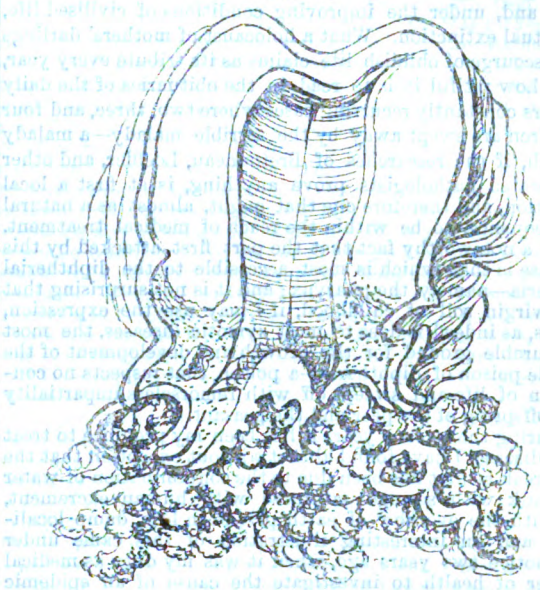
EXCISION OF THE ENTIRE UTERUS FOR CANCER.

WITH NOTES OF A SUCCESSFUL OPERATION.

BY CHAS. E. JENNINGS, F.R.C.S. ENG., M.S.,
ASSISTANT-SURGEON TO THE CANCER AND NORTH-WEST LONDON HOSPITALS.

THE object of two lectures which I delivered at the Cancer Hospital this session was to advocate vaginal extirpation of the uterus, for early cancer of the cervix, as the operation to be usually performed, to the exclusion of other methods of treatment, as soon as the diagnosis is established. History teaches us that in the past the mortality which attended excision of the entire uterus was so great that the operation could only be considered a desperate remedy to be adopted for desperate conditions; to-day it is struggling for a settled place in surgery, and for the near future why should not extirpation of the uterus be followed by a measure of success equal to that which now accompanies other severe but recognised surgical procedures on abdominal organs? From statistics contained in a valuable paper on extirpation of the uterus, presented to the Obstetrical Society by Dr. Wm. Duncan in January, 1885, it appears that of 137 cases of abdominal extirpation 38 recovered and 99 died, being a mortality of 72 per cent., but of 276 cases of vaginal extirpation 197 recovered and 79 died, being a death-rate of 28·6 per cent. The former group of operations were divided among seventy-one and the latter among sixty-nine surgeons, and therefore it seems right to conclude that, except under some special circumstances, the vaginal should be preferred to the abdominal method of uterine excision. This conclusion is strengthened by the fact that many of the operations in the two categories were performed by the same operators. For example: Martin performed 6 hysterectomies by the abdominal method, and all the patients died; he operated 60 times by the vaginal method, with 47 recoveries and 13 deaths. Of 8 abdominal extirpations of the uterus by Billroth, 3 recovered and 5 died; of 12 patients operated upon by the same surgeon by the vaginal method, 8 recovered and 4 died. Of 8 abdominal operations by Schroeder there were 3 recoveries and 5 deaths; whilst of 27 vaginal extirpations there were 19 recoveries and 8 deaths. Guided by these statistics, I elected to excise the uterus per vaginam in the following case, where the removal of the entire organ was the only means by which life could possibly be prolonged beyond a very limited period.

On Sept. 1st, 1885, Mrs. R——, aged thirty-five, who had been twice married, attended at the Cancer Hospital, complaining of an offensive, sanguineous vaginal discharge, associated with pelvic pain and other symptoms, of some months' duration—viz., since the birth of her last child. One of her sisters was reputed to have died some years ago of "cancer of the bladder." Physical examination disclosed an infiltration of the cervix uteri with ulceration around the os externum. The disease being apparently well localised, it was decided to destroy the neoplasm and surrounding tissue with caustic potash. This was accordingly done on Sept. 5th; several sticks of caustic potash were employed, the cervix being previously painted liberally with a solution of muriate of cocaine to mitigate the pain. After the separation of the sloughs bleeding returned, and the necessity for a greater destruction of the cervix being evident, the patient was anæsthetised on Sept. 15th. The chief portion of the diseased cervix was scraped away with a curette, posteriorly as far as the junction of the cervix with the vagina, and Pacquelin's thermo-cautery was applied freely to the raw surface. This operation appearing satisfactory, the woman was duly discharged and treated as an out-patient; but the pain and hæmorrhage having soon returned, she became confined to her bed at home, and at the request of Mr. Prowse, who had been summoned to attend her, I examined the patient in consultation with him on Oct. 28th. The general strength had then declined considerably, and there were marked signs of anæmia. The vagina was flaccid, the uterus enlarged and a little prolapsed. That portion of the anterior lip of the cervix which remained after the previous operations was infiltrated; the posterior lip was absent, so that the finger on being passed upwards along the posterior vaginal wall glided into a conical rugose cavity, whose apex seemed limited superiorly by the internal os. The speedy recurrence and the rapid growth of the neoplasm convinced



Digitized by Google

me that the only means of averting death lay in extirpating the uterus as soon as the necessary arrangements could be made for the operation. But I specially pointed out that the disease had now so far progressed that, even if the uterus were extirpated successfully, a secondary growth might appear at a later date. Moreover, the present condition of the patient would add to the danger of an operation severe *per se*, so that its choice or rejection had to be left to the decision of the patient and her relatives.

As to the methods for vaginal hysterectomy, there are two chief varieties. By the first, extreme and continuous traction is made upon the cervix, whilst the vagina is being severed and the uterine ligaments divided with scissors or knives and separated from the organ with the handle of the scalpel; according to the second plan, the uterus having been first drawn down in order to admit of the separation of the vagina either entirely or partially, the speculum is withdrawn, the operator's hand is introduced into the vagina, and the remainder of the operation is completed with the fingers. Blundell strongly advises that the operation should be conducted by the latter method. It is easy to understand how, by this plan, the danger of wounding the bladder, ureters, small intestine, or rectum is minimised. The chief uterine vessels can be ligatured or clamped before division, and the duration of the procedure diminished. By the former, injury to the important pelvic structures with the point of the scalpel can hardly be avoided; the hæmorrhage from the divided vessels obscures the field of the operation; the traction on the uterus drags down also the viscera which are in anatomical contiguity with it, and the satisfactory enucleation of the uterus is rendered most difficult. More than fifty years ago Blundell removed the uterus four times, with three deaths. His mortality was probably due to hæmorrhage, for he possessed no means of securing the divided vessels. The vaginal arteries will rarely give much trouble if unsecured; but vessels such as the uterine and ovarian arteries cannot safely be trusted unligatured, even though they be severed from the uterus by avulsion or be slightly twisted by flexion of the organ.

On Oct. 30th, 1885, at 2.30 P.M., I operated in the following manner. The anæsthetic was administered by Dr. Fenton-Jones, and Messrs. Prowse, Shaw, and Dove assisted me. The patient was placed in the lithotomy position, and the vagina was thoroughly syringed out with a carbolised solution and afterwards sponged dry. A duckbill speculum was then introduced into the vagina, the urine drawn off with a catheter, a full-sized curved sound passed into the bladder, and the viscus supported against the pubes by this instrument during the operation. The ulcerated cavity was plugged with iodoform wool (10 per cent.) and a stout silk ligature inserted through the cervix. The cervix and the upper part of the vagina were dusted with finely pulverised iodoform, and semilunar incisions were made, posterior and anterior to the cervix, through the vagina. Laterally the vagina was left intact, the parts here being those where the chief branches of the vaginal arteries enter the uterus. The speculum was withdrawn and traction made upon the ligature. But the cervix was so friable from the cancerous deposit that the ligature tore through the neoplasm, and it was found necessary to grasp the cervix as high upwards as possible with volsellum forceps. The left index-finger, well carbolised, was introduced through the opening in the posterior cul-de-sac between the posterior wall of the uterus and the peritoneum. The latter structure was slowly separated from the uterus as high as the body, and then torn through so that the exploring finger passed into Douglas's space. The right forefinger was passed through the anterior semilunar opening, and the bladder being well supported on the staff, no difficulty was experienced in separating the ureters from the uterus and roof of the vagina, and the peritoneum from the uterus for some distance, when it also was torn through. The speculum being introduced into the vagina again and the anterior vaginal wall elevated with a spoon, the narrow lateral strips of vaginal membrane which had been allowed to remain attached to the uterus were snipped through with blunt-pointed scissors. The hæmorrhage which occurred was so slight that it was disregarded. The uterine arteries, with the connective tissue surrounding them, were grasped with a pressure-forceps on each side of the cervix, and divided with scissors on the median sides of the forceps. Such profuse hæmorrhage occurred from the uterine extremities of these vessels that the wire of an écraseur was quickly adapted around the cervix and pushed upwards as far as possible above the mouths of the vessels to control it. This having been accomplished, the proximal extremities of the uterine arteries were ligatured and the pressure-forceps were removed. The wire of the écraseur was slowly tightened in order to effect a supra-vaginal amputation of the cervix, but very soon the wire snapped asunder, and there being no renewal of the hæmorrhage, the extirpation was proceeded with by introducing the left hand into Douglas's space, and with the tips of two fingers, which surmounted the right side of the uterus, catching a stout silk ligature passed upwards in front of the uterus on a blunt needle. A similar manœuvre was repeated on the left side of the uterus, and the ligatures, which included the round and broad ligaments, Fallopian tubes, and the other structures passing from the uterus on either side and contained within the alæ vespertilionis, were tied as tightly as possible. These ligatures were satisfactory in so far as they constricted the broad ligaments and their contents into more or less rounded cords. But they were unsatisfactory in two respects: first, they lay close to the sides of the uterus; and, secondly, they would not be tight enough to maintain their grasp upon the parts contained within them if the uterus were cut away. Accordingly, two straight Wells's pressure-forceps, each 6¾ in. in length with jaws 1½ in. long, were employed to grasp the broad ligaments on the outer side of the ligatures. The broad ligaments were carefully cut

FIG. 1.

through with scissors close to the uterus, which was easily extracted, and the two ligatures slipped away. The left ovary, rather larger than the normal, protruded into the vagina, and it, with the morsus diaboli, were removed with part of the tube after the application of a silk ligature. The pelvic cavity was carefully cleansed with carbolised sponges. All hæmorrhage having ceased, the vagina was packed with iodoform wool. The handles of the pressure-forceps, which just extended beyond the ostium vaginæ, were tied together, a T-bandage applied, and the patient placed in bed, the entire procedure having occupied an hour and a half.

The pressure-forceps were removed by Mr. Prowse thirty hours after the operation, and on Nov. 1st I saw the patient with him in consultation. There being then considerable abdominal pain and tympanites, the temperature having risen to 102° F., the pulse being wiry, and the features having a pinched expression, we decided to seek the advice of Sir Spencer Wells. He advised that the quinine and opium which had been given should be continued, and that the vagina should be kept free from any source of infection by frequent sponging with antiseptic solutions. He expressed a hopeful prognosis, which proved correct, for the temperature fell and did not rise again above 100°. The patient recovered without manifesting any further symptoms of anxiety, and all discharge from the vagina ceased on Nov. 20th. After the removal of the uterus its anterior wall was incised in the median line, as shown in Fig. 1. It

Digitized by Google

then appeared that the uterus was invaded by the new growth to a greater extent than we believed before the operation. There was no enlargement of the obturator glands at the time of the operation, but I learn from Mr. Prowse that recurrence has unfortunately taken place in the vagina. He writes as follows:—"March 7th, 1886: I first noticed some four weeks ago that the walls of the vagina were becoming somewhat harder than usual, and a fortnight ago some suspicious granulations made their appearance in the line of the cicatrix; these have now developed into well-marked ulcerations, and the vaginal walls have increased in hardness and have become quite nodular to the touch. I have not the slightest doubt as to the recurrence of the disease."

(To be concluded.)

NOTES ON DIPHTHERIA.

BY N. E. DAVIES, L.R.C.P.L., M.R.C.S.

ANY researches, however humble, likely to throw light on the pathology and successful treatment of diphtheria must of necessity be acceptable at any time, for a disease the germ of which originates in filth, overcrowding, and bad sanitary arrangements is surely one subject to considerable amelioration and, under the improving conditions of civilised life, eventual extinction. What a holocaust of mothers' darlings this scourge of childish life claims as its tribute every year, and how pitiful it is to read in the obituaries of the daily papers constantly recurring cases where two, three, and four children are swept away by the terrible malady—a malady which, if the researches of Bretonneau, Loeffler, and other celebrated pathologists prove anything, is at first a local affection, and therefore one that ought, almost as a natural consequence, to be within the reach of medical treatment. It is a noteworthy fact that the part first attacked by this disease is that which is most accessible to the diphtherial bacteria—namely, the pharynx; and it is not surprising that the virgin soil of childhood, if I may use the expression, offers, as indeed it does to most zymotic diseases, the most favourable ground for the growth and development of the subtle poison of diphtheria—a poison that respects no condition of life and sweeps off with remorseless impartiality the offspring of the peer and the peasant.

During the twenty years it has been my province to treat this disease, I have found almost without exception that the outbreak at first has been due to the contamination of water or milk with sewage saturated with human excrement, or with the overflow of earth privies in low, damp localities, and an interesting illustration of this came under my notice two years ago, when it was my duty as medical officer of health to investigate the cause of an epidemic in a little village near Sherborne, where an entire family of five children were destroyed by it, and where numerous other cases occurred, some of which ended fatally. In this case a spring of pure water was conveyed down a hill in a leaden pipe; this opened into a stone trough, and from this trough it again passed underground through some earthenware pipes (which were not cemented properly together) into a second trough, and thence it ran as an open stream through a thickly populated village lying in a valley about a quarter of a mile long. Now, between the two troughs I have mentioned was an open privy, the liquid contents of which had percolated through the earth, and thence through the joints in the earthenware pipes into the second trough, afterwards, of course, contaminating the whole stream in its downward course through the village. Now mark this circumstance: a few houses near the first trough used their water from that, and these escaped the epidemic; whereas those who used their water from the second trough and from the stream suffered more or less, and the family in which, as I have mentioned, the five fatal cases occurred, went for their supply exclusively to the second trough, and therefore got the poison in its most concentrated form.

Now what does the history of this epidemic teach? That, at all events in its first incursion, the cause was strictly local, and that the bacterial poison had its origin between the two troughs, and in the most fatal period of the epidemic, infected its victims by the mouth and alimentary canal through drinking the water. I opine that, such being the case, it is only natural to suppose that in the spongy substance of the tonsillar glands the micrococcus finds a congenial home,[1] and from thence by fibrinous infiltration and inflammation invades the blood and the whole system, and this in some cases so rapidly as to destroy life in a few hours. I call attention to this fact simply to show that an epidemic, at all events at first, spreads by direct contact with the poison—i.e., by imbibition. Afterwards, as a matter of course, it may spread by other means, and its virulence be intensified by conditions of climate and atmosphere.

There are many secrets in nature yet to be unravelled, and one of them is—Why should epidemic diseases in certain seasons be more virulent, more general, and more widespread than in others? Their fungoid origin has its prototype in the vegetable world; in some seasons and localities the mildew, the oidium albicans, or, better still, the common mushroom, thrives luxuriously, then perhaps for years (at least in this neighbourhood) it becomes almost forgotten, not because the season is not propitious, but because some peculiar or climacteric influence is wanting; so, I take it, with diphtheria, that though sporadic cases may start a localised epidemic, yet such a one as that which visited England in 1858 and 1859 requires an occult stimulus, the secret of which is at present buried in profound darkness. Hence for the present it is wise and right, I believe, to agree with Loeffler, Empis, Kellog, Avery, Bretonneau, and many other celebrated pathologists, that the disease is at first a local disease, and that the constitutional symptoms depend upon general infection from this local lesion, and their mildness or virulence upon locality, atmospheric conditions, age, heredity, and the surroundings, healthy or unhealthy, of the victim, and perhaps I may add, the amount of the poison that has been imbibed; and acting on this belief, how important it is, when an outbreak occurs, to endeavour in every way to localise it and prevent its spreading by means of contaminated water, milk, and clothing, or by intercommunication with infected areas, and by energetic treatment to stamp it out. Some years ago I resided with a practitioner in Suffolk, where sporadic cases of diphtheria seem to be common, and I must say his mode of treating the disease was eminently successful: it consisted in mopping the throat and pharynx thoroughly out daily with dilute nitro-muriatic acid, and administering iron; he also insisted that, however ill the patient might be, he or she should be taken frequently into the fresh air. This is really almost identical with the treatment laid down by Bretonneau, Ellis, and others; it was rather rough treatment, it is true; but desperate diseases require desperate remedies; and as its aim was to destroy the local lesion from which all subsequent mischief arises, it must have been good and in the main correct—at least results proved it so.

My plan of treating the disease is as follows; it answers the same end, and does not alarm the patient; and, even at the risk of being considered egotistical, I must say that it has been highly successful in the large number of cases that have come under my observation during the last eighteen or twenty years. I assume that the case is treated in its early stage—the only stage in which local treatment can really avail; for when once the blood becomes impregnated with the fungoid micrococcus or bacteria of diphtheria, the poison is then deposited in organs, such as the trachea or the bronchi, beyond the reach of local treatment; and it becomes a question whether the constitution of the patient can eliminate the poison, and nature, generous nourishment, iron, &c., once more re-establish convalescence. In the first place, in any affection of the throat I lose no time in examining it, and watch carefully for the unmistakable washleather-like creeping deposit of diphtheria, or the symptoms of its sister diseases, follicular tonsillitis, croup, and scarlatina; if it turns out to be diphtheria, I give a mixture containing six drachms of the tincture of the perchloride of iron to five ounces of sweetened water, and at this strength, *undiluted*, I insist that the child shall take every hour for twelve hours a dessertspoonful (if the patient is older or an adult, a much larger dose), and that this dose shall be repeated, whether vomiting occurs or not. At this strength I find in that time, or a few hours more, that the growth has a shrivelled look and its vitality is destroyed. I then reduce the dose and extend the intervals, and, as I believe, with many others, that iron has some specific

[1] In 98 per cent. of the cases the pharynx is first attacked.

Digitized by Google

power of arresting the septic action of the poison in the system, continue it for two or three days or longer, keeping up the strength with strong beef-tea, milk, and port wine; if these cannot be taken, I use an enemata every four hours of equal parts of beef-tea, port wine, and cream or milk. The advantages of this treatment over the local application of caustics is that it reaches every part of the pharyngeal tract likely to be affected, and is, as I mentioned before, strong enough, given in this way, to destroy the vitality of the fungus of diphtheria; and let me here impress the absolute necessity of keeping a thorough draught of fresh air constantly passing through the room, for how can it be expected that a blood poison can be eliminated if it is continually breathed again? As well might one attempt to resuscitate a person dying from inhaling a poisonous gas without first taking the sufferer into the open air. It is needless to say that this treatment in the generality of cases should be supplemented by giving barley-water, sweetened in the case of children, containing two drachms of chlorate of potash or other antiseptic drug, to the pint, but I prefer chlorate of potash, for it is not unpleasant to the taste, and children will drink it readily.

Now, roughly speaking, this is the mode of treating the disease that I have found most successful, and one by the aid of which I have seldom had occasion to resort to more severe measures. The waywardness of a spoilt child will sometimes upset the best calculations by absolutely refusing to swallow anything; then it becomes necessary to resort to mopping the throat, and Bretonneau's mode of applying caustic solution is worth inserting here. He says: "In order to apply the acid to the base of the pharynx and upon the tonsils, I make use of a fine sponge about the size of a pigeon's egg, firmly fixed at the end of a flexible rod of whalebone, and I give to this rod a suitable curve after warming and softening it at the fire. Before touching the membranous spots on the throat, I take care to dip the sponge in concentrated acid and to press it so that it shall remained simply moistened. I take this precaution so that in the convulsive movements of the isthmus of the throat the expressed liquid may not extend its action beyond the point I intend to cauterise." This method, it will be seen, has the advantage of preventing the caustic solution going beyond the area affected and setting up violent inflammation of the pharynx or larynx. All the novelty I claim for my system of treatment is that I give much larger, stronger, and more frequently repeated doses of the perchloride of iron than I have ever seen advocated by others, and that if the destruction of the cause of the local lesion is the proper thing to do, as I believe it is, it answers the purpose, with the advantage of placing in the blood a drug which arrests the rapid deterioration of its healthy constituents produced by this disease, with its after-train of disastrous lesions.

Sherborne.

NOTE ON A CASE OF

NERVE-STRETCHING FOR FACIAL SPASM, OPERATED ON FIVE YEARS SINCE.

BY F. A. SOUTHAM, M.B.OXON., F.R.C.S.,

ASSISTANT-SURGEON TO THE MANCHESTER ROYAL INFIRMARY, AND SURGEON TO THE CLINICAL HOSPITAL FOR WOMEN AND CHILDREN.

IN THE LANCET of August 27th, 1881, I published particulars of a case of stretching of the facial nerve for clonic spasm ("convulsive tic") of the muscles of one side of the face of two years' duration, occurring in a woman aged fifty-nine, who had previously been under the care of Dr. Ross. The operation, which was performed in March, 1881, was followed by complete paralysis of all the muscles supplied by the facial nerve on the corresponding side. About five weeks subsequently, the affected muscles gradually began to regain their power, and at the end of five months the paralysis had entirely disappeared. As no return of the spasm has taken place, and a period of five years has now elapsed since the operation, the cure may be regarded as complete and permanent, and on this account the case may, perhaps, be thought worthy of further record.

In a recent article by Prof. Zesas,[1] particulars are given of the results of nineteen cases of this operation collected from different sources. In only two other instances—viz., in one case operated upon by Zesas himself, and in another by Navratil—in addition to the one above referred to, has the cure been permanent. In four cases there was considerable improvement, while in ten the operation failed to give more than a temporary relief; in the remaining two cases the result was doubtful, as their subsequent history was not followed out. Inasmuch, however, as benefit has resulted in seven out of seventeen cases, Zesas is of opinion that the operation should still be performed whenever the spasm is not due to intra-cranial lesions.

[1] Wiener Medicinische Wochenschrift, Nos. 27, 28, 1885. An abstract of this paper, by Mr. C. Atkin, F.R.C.S., will be found in the Medical Chronicle, Jan. 1886.

FRACTURE OF THE BASE OF THE SKULL, WITH OPTIC NEURITIS; RECOVERY.

BY W. T. JACKMAN, M.R.C.S., &c.

THE following case is of interest, showing, as did a case published by Mr. Sydney Jones in THE LANCET of Jan. 10th, that the complication of optic neuritis does not always indicate a bad prognosis in fractures of the skull.

M. H——, aged thirty, a coachman, of medium height, spare build, and temperate habits, was thrown from his horse on the evening of Dec. 6th, 1885. He was picked up in an insensible condition and carried to the stables, a distance of about one hundred yards, by two men, who left him for about an hour, and on their return, finding he had gone, they concluded he had only been stunned, and therefore did not say anything about the accident to anyone. Next morning he walked from his house (the lodge at the entrance of the drive) to the stables. He then complained to some men of headache, but they do not seem to have noticed anything peculiar about him. A short time afterwards he was missing and could not be found until 2 P.M., when he was discovered on one of the grooms' beds over the stable in a drowsy state and complaining very much of headache. When I visited him about 3 P.M. I found him drowsy and troubled with severe pain in the head, which was worse on the left side under the occipital bone, and suffering from cerebral sickness, which on inquiry I found had been persistent every half-hour or so all the morning. Tongue clean; bowels not open; temperature normal; pulse slow and laboured. On examining the head, some dried blood was found in the meatus of the left ear and a slight wound over the left occipital protuberance, which had evidently bled a little, and was surrounded by a swelling of about the size of a hen's egg. The pupils were sluggish to light. There were no other signs of fractured skull. The patient did not remember anything which had happened since he fell from the horse, and could not account for being in his present place. I found he had walked home after the men had left him the previous evening in the stable, had supper with his wife, passed a restless night, but there had been no vomiting. He had eaten a small breakfast and only complained of headache to his wife, who thought he was suffering from a bilious attack. I ordered ice to the head, perfect quiet, and ten grains of bromide of potassium to be taken every four hours.

Dec. 8th.—Consultation with my partner, Mr. T. Simpson, and diagnosis confirmed. Patient had passed a restless night. Vomiting less frequent; pain in the head still continues bad. Temperature 99°; pulse slow and feeble. Tongue slightly furred. Bowels not open. On examining the optic discs, the left was found to be normal, the right disc was hazy, and the veins were larger than normal, the arteries if anything smaller.—10th: Patient passed a bad night. Vomiting ceased. Bowels open after fifteen grains of calomel. Temperature 99·5°. Right disc red and edges hazy. Vessels as yesterday.—11th: Bad night. Temperature 100°. Pulse very weak. Right disc less red and veins smaller.—12th: Better night. Temperature 99·5°. Pulse stronger. Right disc less red and less hazy. Patient expresses himself as feeling better. Ice discontinued.—13th to 22nd: Gradual and steady improvement. Both discs normal. The patient was removed to his own home, and was able to resume his work on Jan. 16th, 1886.

It is interesting to note that, although the patient received the injury on the left side of the head, the bleeding was from the left ear, and that the inflammatory mischief was evidently on the left side of the head, as indicated by the persistence of the left hemicrania, yet the right optic disc

Digitized by Google

alone was affected; as far as could be judged vision was not affected, though exact information as to the field of vision was impossible under the circumstances.

This is the third case of fracture of the skull which occurred in our practice last year, and all recovered. One was in a child five years of age, who had bleeding from the ears, nose, and mouth, and well-marked symptoms of fractured base. The third was in a boy aged five years, with depressed fracture of the right parietal bone.

CHARING-CROSS HOSPITAL.

A CASE OF ACUTE CHOREA WITH PREGNANCY; INDUCED PREMATURE LABOUR; RECOVERY.

(Under the care of Dr. A. J. POLLOCK.)

THIS case is a good example of the form of disease known as "chorea gravidarum," which appears to be much more severe than any other variety of chorea. Dr. Barnes[1] estimates the mortality at one to three, and gives a long table of cases, from which it would appear that this affection usually comes on during the first three months of a first pregnancy; and Dr. Wilks[2] has observed that a large proportion of those who are attacked are unmarried girls. Dr. Ross[3] gives the age of the majority of those affected as from twenty to twenty-three; whilst Trousseau[4] refers to sixteen instances of the disease in which the age was from nineteen to twenty only. The etiology of the disease is not clear. Trousseau would refer it to the chlorotic condition which often accompanies pregnancy, whilst others would ascribe it to the nervous condition of such patients. Dr. Wilks' theory would lend support to this view, and the case which we publish gives additional proof of its correctness. There does not appear to be any previous history of rheumatism or of rheumatic affections in the majority of the cases recorded, though in some there had been a previous attack[5]. The progress of this case after the uterus had been emptied of its contents was most satisfactory, the condition of the patient before this proceeding being most alarming.

A. T——, aged twenty, kitchen-maid, unmarried, was admitted on May 31st, 1885, suffering from chorea. Her illness dated from May 28th, and its onset appeared to be unusually sudden. No change in her demeanour was noticed until the movements began, and on the third night of her illness she was slightly delirious. There was no history of rheumatism in the family, nor had the patient ever suffered from rheumatic fever herself. Her mother suggested that the cruelty of one of the other servants had some causative relation to the attack, as her daughter had often complained of it, and during the onset talked of nothing else.

On admission, three days after the supposed commencement, the patient presented all the usual phenomena of chorea. The movements were more marked in the upper than in the lower extremities; both sides were equally affected. No paresis could be made out. She appeared to understand most of what was said to her, but was quite unable to give any connected account of her illness. Articulation was indistinct. No physical signs of disease could be found in the chest or abdomen. The patient was about four months pregnant.

On June 3rd (four days after admission) her condition became much worse. She was now delirious all day, and paid no attention to anything that was said to her. The movements were so violent that partial restraint was employed. Arsenic, bromide of potassium, chloral hydrate, and conium were one after another employed in large and frequently repeated doses, but with negative results. The typhoid state rapidly supervened, though the temperature remained normal.

On the afternoon of the 12th the os uteri was dilated by the finger. During the night there was a copious blood-coloured discharge, and in the morning a fetid four months' fœtus was found in the vagina. The cord was fairly firm. A solution of perchloride of mercury (1 in 1000) was ordered to be injected into the uterus twice daily.

From this time improvement was gradual and continuous. In two days (June 15th) simple questions could be understood and answered, and the movements were distinctly less violent. The temperature rose to 101° on the 15th, reaching 104·5° on the 16th, but fell to normal on the 17th. On the 23rd it rose to 102°, but regained its normal character the same day. On the 27th the injections, which had been reduced to one daily, were altogether discontinued. The movements had almost ceased, but the patient's intellect was still clouded. At the time of discharge (July 22nd) the movements had altogether ceased, and, beyond being rather dull and stupid, the patient was in very good health.

LIVERPOOL INFIRMARY FOR CHILDREN.

CROUPOUS PNEUMONIA AND GANGRENE OF THE LUNG; DEATH; NECROPSY.

(Under the care of Dr. OXLEY.)

THE patient, a boy six years of age, lost both parents from lung disease, a sister had a leg amputated for disease of the knee, while another sister suffers from keratitis and caseous cervical glands. The patient has always been delicate, and for some months he has had a cough. When admitted into hospital he was found to have a very rickety chest, his temperature was 103°, and his respiration 44 per minute. His cough was frequent, and he had a scanty, viscid, yellow expectoration; the breath was rather foul; he had also signs of consolidation of the lower lobe of the right lung. In two days the breath became extremely offensive, the odour being fæcal in character and permeating the whole ward; signs of a cavity also appeared in the base of the right lung. The consolidation gradually crept over the whole lung, the pulse becoming more and more feeble. The smell persisted, though not quite so offensive as at first, owing to antiseptic inhalations. The patient died after being in hospital thirteen days.

After death the right pleura was found generally adherent; the right lung was in a state of grey hepatisation; the lowest lobe contained a cavity about the size of a small orange; the walls were rough and of a dark greenish-blue colour, it contained some ichorous fluid; there was a second smaller cavity in the middle lobe. The lung substance round these cavities was of a pale greenish-blue colour; the tissue in the upper lobe was of a pale fawn colour, and was absolutely airless. The left lung was œdematous. The mediastinal and bronchial glands were caseous, and in most of them the caseous material was more or less calcified. None of the glands were gangrenous. There was no heart disease. No tubercle was found in any part of the body.

MULTIPLE ABSCESS OF THE LIVER FOLLOWING IMPACTION OF A PIN IN THE VERMIFORM APPENDIX, COMPLICATED BY MENINGITIS.

(Under the care of Dr. M'CLELLAND.)

The patient, a girl aged eight years, came under observation early in the year; she was then complaining of fever and pain in the right shoulder. Her family history was good, and she had been a strong healthy child. It was found after death that fourteen months before she had swallowed a pin in school; about that time she complained of pain in the region of the right groin. Nine weeks before admission into hospital she caught a cold, and during the next week was feverish and had pain in her right shoulder. She had then no cough; her complexion was muddy, but never yellow. When she came under notice she had a high temperature, which tended to remit in the morning; she was very restless and thirsty, perspired profusely at times, and her urine was normal. She was constipated, though in the later stage of her illness she had some diarrhœa; there was nothing abnormal to notice in the motions. There were signs of con-

Digitized by Google

solidation of the base of the right lung. For some days nothing definite was noticed in the abdomen, but the liver enlarged rapidly, ultimately reaching to the level of the umbilicus. For a week before death the patient was in a typhoid condition, and two days before she died she had convulsions localised to the right side, and involving the mouth, arm, and leg. She never had any jaundice, her complexion being muddy throughout the illness. She died from compression of the brain having been twenty-six days in hospital.

When the body was examined, the liver was found very greatly enlarged, weighing 4 lb. 8 oz.; the upper part of the right lobe contained an abscess cavity the size of a small orange, full of thick pus; the whole of the right lobe was honeycombed by abscesses of very varying size, the largest being about the size of a filbert; the left lobe, though free from apparent disease, was very much enlarged. The gall-bladder contained a fair amount of golden yellow bile; there was no obstruction of the bile-ducts, and the upper part of the intestine was bile-stained. The vermiform appendix was thicker and longer than usual, and was adherent half an inch from its distal end to the pelvic wall; on separating the adhesion, the wall of the appendix was found very thin and ulcerated on its inner surface; the adhesion was found to correspond to the head of a pin of large size, which was impacted in the appendix head downwards. There was no sign of recent inflammation. The mesenteric and lumbar glands were normal. On opening the skull, the cranial sinuses were found to be distended with firm clot; about the middle of the longitudinal sinus the clot contained a drop of pus. There was a patch of intense congestion around the fissure of Rolando and over the paracentral lobule of the left side, the pia mater of these parts being dull and sticky. An abscess about the size of a large pea was found in the cortex of the right occipital lobe near its centre.

There can be little doubt that the hepatic abscesses were due to a septic embolus or to several emboli carried by the mesenteric veins to the liver. A very similar case is to be found in Dr. Murchison's book on the liver; but in that case there was only ulceration of the vermiform appendix, no cause for the ulceration being found. The present case would suggest that some foreign body was also the original cause in Dr. Murchison's case.

CUMBERLAND INFIRMARY.

CASE OF FÆCAL ACCUMULATION CAUSING SYMPTOMS OF PARTIAL OBSTRUCTION; REMARKS.

(Under the care of Dr. LOCKIE).

THE following notes have been furnished by Mr. G. Francis Smith, house-surgeon.

Robert M——, aged sixty-eight, was admitted on Jan. 17th last, complaining of distension and pain in the abdomen, with constipation. He had for some time previously (between two and three weeks) been suffering from frequent small watery evacuations, which had been treated as an ordinary case of diarrhœa.

On admission his tongue was slightly furred, the abdomen distended and tympanitic, but the pulse good. There was nausea without vomiting. He was given a dose of castor oil and opium, which produced a small evacuation from the bowels and temporary relief to the distension, nausea, and discomfort. On the following day the dose was repeated, without result. From this time up to Jan. 25th (eight days) the abdomen was more or less distended, the movements of the intestines, seen through the abdominal parietes, and constipation persistent. No tumour or localised fulness could be detected through the abdominal wall or per rectum. On the 25th a long œsophageal tube was passed up the rectum. The tube seemed to meet with an obstacle about six inches up the gut, and having passed this gave free exit to a large quantity of flatus, its escape being assisted by pressure on and kneading of the abdominal wall. In a few minutes the abdomen was flattened and flaccid, but even then nothing abnormal could be discovered on palpation. The flatus, however, reaccumulated in a day or two. From time to time various drugs were employed as aperients, or with a view of improving the tone of the gut, as it was thought the distension might be due to atony. Aloes and myrrh, sulphur and guaiacum, strychnia, belladonna, and ergot were in turn given, without effect. Galvanism was also employed. The flatus reaccumulated and constipation continued. The distension was relieved every second or third day by the use of the long tube. At the third introduction warm water was injected high up into the gut, and by this means exit was given to a quantity of frothy, light-coloured fæces, containing a number of black currant skins. On being questioned, the patient declared that "he had not tasted a currant since Christmas Day, but at that time he did eat a large amount of currant cake." For the next four or five times of the long tube introduction, some of these currant-skins came away with the fæces. For rather more than three weeks the bowels were systematically relieved in this manner, constipation otherwise remaining persistent. All this time no tumour could be felt in the abdomen; but from time to time the patient felt sick, lost appetite, and had a coated tongue and rather offensive breath. At the end of this time, on one occasion the tube was allowed to remain in the bowel for about half an hour. Some feculent matter and flatus passed during this time. The patient then had a hot bath, and after this his bowels acted naturally for the first time since admission. In two motions about six quarts of fluid feculent matter were passed, containing large quantities of black currant skins similar to those already noticed. From this time no reaccumulation occurred, and the bowels became regular, without having recourse to drugs. The patient was discharged on March 10th, apparently quite well.

The case is of interest, as showing how accumulations may occur, giving rise to obstructive symptoms, without being discovered by physical examination; and also showing the value of the long tube as a diagnostic and a therapeutic agent. Although no tumour could be felt, it was evident that the obstruction, however brought about, was in the large intestine and probably in the sigmoid flexure. The colon, when distended, could be easily traced, and its vermicular movements were very marked. Relief was never given until the tube had entered about six inches, and frequently not until a foot had been introduced.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Intra-cranial Cyst.—Acute Nephritis in Lambs.—Hydatid of Liver embedded in large Syphilitic Deposit.—Valvular Obstruction of Ureter.—Embolism of Abdominal Aorta.—Septic Aortitis.

AN ordinary meeting of this Society was held on Tuesday last, Dr. J. S. Bristowe, F.R.S., President, in the chair.

Mr. R. W. PARKER read the report of the Morbid Growths Committee on the Intra-cranial Cyst shown by Dr. Macdonald. In the opinion of the committee the cyst was a subdural hæmatoma; they did not think that there had been any new formation in the cyst wall, which was possibly of congenital origin, or due to hæmorrhage produced during birth. Fresh hæmorrhage appeared to have occurred, and possibly explained the paralysis. Mr. Shattock and Mr. Parker signed the report.

Mr. ROGER WILLIAMS exhibited specimens of Acute Nephritis in Lambs. The disease began soon after birth with difficulty in walking, the new-born falling down and lying on one side, sometimes with choroid movements, without loss of consciousness, without difficulty in breathing or cough; sucking was not impaired nor the appetite. The disease appeared to attack the lambs of ewes imported from Scotland, and especially those whose female parents were served by a ram who was far from vigorous, having to spend his strength on too many ewes. At all events, it was found that if a ram only served ten ewes the progeny were vigorous and did not become affected with the disease. Mr. Williams had examined two lambs, one that died of the disease and another killed at three weeks old. The urine was albuminous and acid, whereas it should have been alkaline. There were no renal casts, crystals, pus, or blood. The capsules of the kidneys stripped off easily, exposing a surface studded with congested stellate veins. The cortex was swollen and soft, pale and yellowish in colour, whilst

Digitized by Google

the pyramids were firm and deep-red in colour. The disease was an acute tubal nephritis; the tubular epithelium was much degenerated, not staining with logwood, whilst the interstitial tissue was normal. The changes in both cases were identical, though one was in a more advanced condition than the other. Nothing abnormal was detected in any of the organs, and the spinal cord was healthy. Some of the lambs were born with the disease, and soon succumbed.—Dr. PYE-SMITH said the normal reaction of lamb's urine whilst suckling was acid.

Dr. G. N. PITT showed a specimen of old Hydatid of the Liver embedded in a large Syphilitic Growth. A man aged thirty-nine came last year under Dr. Goodhart's care, with a large painless globular tumour, with a firm sharp lower margin, occupying the left lobe of the liver and extending down nearly to the umbilicus. Thirteen years previously he had contracted syphilis, and three years later had been castrated for syphilitic disease of the testicles. In 1878 he had an attack of slight aphasia and right hemiplegia, which soon improved. In 1881 he was under Dr. Fagge's care with a large, painful, irregular tumour connected with the liver, which was diagnosed as of gummatous and lardaceous nature. Since then it had diminished in size. The urine at this time was normal. Previous to this he had worked as a ship's carpenter, and a few months later he was able to resume his work. On his admission in 1885 he was also suffering from œdema, and was passing urine of specific gravity of 1007, containing one-third albumen and in quantity about seventy ounces daily. After eight weeks he became uræmic and died. At the necropsy large white kidneys, somewhat lardaceous, were discovered. The left lobe of the liver, which weighed 146 ounces, was entirely occupied by a dense white fibroid mass, measuring six inches and a half by three inches and a half, which enclosed a contracted cavity two inches in diameter filled by numerous gelatinous-looking capsules one inside the other, evidently the remains of an old hydatid cyst. There was a bile-duct (stained yellow) in the middle of this fibroid mass, the adjacent structures being stained yellow. The author drew attention to the great rarity of such a large syphilitic mass without any evidence of caseation or breaking down, and compared this case with two of lymphadenoma occupying the left lobe of the liver, which had occurred at Guy's Hospital. The line of demarcation from the healthy liver structure in all was well defined. The growth in each case was intercellular—i.e., along the lymphatics,—compressing the liver-cells and destroying them; yet some bile-ducts and liver-cells persisted. Undoubtedly some of the large mediastinal tumours and lymphadenomata were syphilitic, and he suggested that the deposit caused by the irritation of the hydatid in the syphilitic subject was closely allied to, if not identical with, some of the large masses which have been described as lymphadenoma. The fibrous trabeculæ were parallel to one another beneath the capsule, but elsewhere they ran irregularly, and the deposit was in the liver substance, and not merely a laminated deposit round the hydatid. When a mediastinal tumour or a lymphadenoma gives the lardaceous reaction it is probably syphilitic.—Dr. SHARKEY referred to a case, published in the Transactions, of syphilitic perihepatitis that caused considerable discussion as to diagnosis during life. The patient died with profuse hæmatemesis. The capsule of the liver was found to be from one to three inches thick, and sections showed many scattered minute gummata, proving its syphilitic nature.—Mr. S. G. SHATTOCK said that in specimens of diffuse interstitial hepatitis there were always miliary gummata to be found, which he regarded as a *sine quâ non* of diffuse syphilitic lesions.

Dr. SAINSBURY read notes of a specimen of Valvular Obstruction of the Ureter. The patient was a female aged thirty-four, admitted into the Royal Free Hospital in a state of stupor, and she died next day comatose, having had epileptiform seizures. One year before admission she had had erysipelas, and had vomited frequently ever since; and once she had hæmatemesis. Epigastric tenderness and albuminuria were observed after admission. At the necropsy the left kidney was completely pyonephrotic; the series of compartments were completely filled with soft white material like thick white paint. The ureter in its upper two thirds was still patent, but its calibre was much diminished; just before entering the pelvis it enlarged suddenly; two small valve-like flaps were found guarding the entrance to the pelvis. The lower third of the ureter was impervious, and no opening into the bladder could be detected. The right kidney was granular. Ebstein had alluded to the existence of an atheromatous material in hydronephrotic sacs. Haller had described valvular obstructions in the ureter, different, however, from the specimen shown.—Mr. SHATTOCK said there was evidence that the interior of the dilated kidney was decidedly diseased; an ulcerative undermining of the mucous membrane of the pelvis might have produced the valve-like projections. He asked if the case were one of tubercle.—Mr. R. WILLIAMS said that in cancer of the uterus with hydronephrosis the ureters presented constrictions and valve-like septa.—Dr. BRISTOWE was inclined to agree with the views of Mr. Shattock.—Dr. H. SAINSBURY said there was no evidence of tubercle in the rest of the body. Tubercle never went on to such complete destruction of the kidney. It was difficult to understand that such perfect valves had been formed by ulceration.

Dr. PRICE (Reading) showed specimens of Embolism of the Abdominal Aorta. The first came from a woman, aged thirty-three, who was admitted into Guy's Hospital in 1883 with abdominal pain and vomiting; there was no history of alcoholism or syphilis. A presystolic bruit was discovered, but no thrill. Eight days after admission the right lower extremity became swollen, mottled, and cold, and finally gangrenous. The left lower limb presented the same changes later on. The urine also was offensive and dark-coloured. At the necropsy the frontal convolutions of the brain were coated with lymph; some thickening of the cerebral arteries and an embolus that did not totally obstruct the left middle cerebral artery were discovered. Mitral stenosis and roughening of the auricular aspect of the valve were present. The ante-mortem clot in the iliac arteries and aorta communicated by means of a small attenuated clot with a post-mortem clot higher up the abdominal aorta. The walls of the bladder and uterus were black and gangrenous. The second case was that of a woman aged forty-six, whose right limb became gangrenous, and was amputated thirteen years ago. In 1883 she was readmitted into Guy's Hospital with albuminuria and gangrene of the other leg. No evidence of cardiac disease was detected during life. At the necropsy some old pericardial adhesions were found about the apex of the left ventricle, whose anterior wall was much thinned and contained several yellowish grains on section, possibly of gummatous nature. The thrombosis extended up to the renal arteries; the embolus had been dislodged from clots in the left ventricle. The vena cava inferior was almost completely obliterated; this was probably the cause of the gangrene of one limb thirteen years previously. The bladder and uterus were healthy.—Dr. J. S. BRISTOWE was not satisfied with the evidence of the embolic origin of the aortic thrombosis. So far as his own post-mortem investigations went, he had not been able to find a single undoubted case of embolism of the aorta due to emboli from the valves of the heart or clots in its ventricles.—Dr. S. TAYLOR referred to a case of abdominal aneurism leading to aortic thrombosis that had been under the care of Dr. Bristowe. Pain and diarrhœa with paraplegia were the symptoms of sudden onset.—Mr. MARMADUKE SHEILD had recorded a case of Embolism of the Aorta, with gangrene of the limb, in THE LANCET of 1880. In another case he had examined, the aorta and heart were extensively diseased, and there seemed to be no doubt of the embolic origin of the aortic obstruction.—Dr. SAMUEL WEST had recorded in the Pathological Transactions a case in which there was no possibility of doubt as to the embolic nature of the thrombosis of the arch of the aorta.—Dr. CARRINGTON also referred to two cases of embolism with mitral stenosis, with clots in the auricular appendix, in which the source of the emboli was unquestionable.—Mr. R. WILLIAMS mentioned the case of a man aged fifty-five, who had embolism of the aorta, the embolus having come from an aneurysm of the abdominal aorta higher up than the obstruction.—Dr. PRICE, in reply, thought there was less doubt of embolism in the second case than the first.

Dr. C. TURNER read a paper on Septic Aortitis, illustrated by four cases. The first was that of a woman aged sixty-two, who had incompetence of the aortic valves. Ulcerated areas of various size and form were seen in the aorta; the endarterium was undermined in many places; much atheroma and calcification was present; the changes were less marked in the abdominal aorta. Masses of micrococci at the base of an ulcer occupying the deeper layers of the inner coat were readily stained with gentian violet after the tissue had been kept in a dilute solution of hydrochloric acid for a short time. Cholesterine crystals also studded the diseased areas. The heart was

Digitized by Google

much enlarged and dilated, and there was some thickening of the valves. The kidneys were granular. She had suffered from rheumatism. The second case was a woman aged forty-eight, in whom the thoracic aorta contained a large mass of fibrinous substance immediately above the aortic valves, and several smaller masses higher up; there were also patches of endarteritis on which the fibrin had formed. The heart was normal. She had had a severe burn of extensive distribution, followed by suppuration and fever. There were two chronic ulcers in the stomach. The third case was a man aged forty-five, who also had much pyrexia; death was due to intra-thoracic hæmorrhage from the left internal mammary artery, the result of a stab in a public-house quarrel. Atheromatous patches were seen in the aorta, and soft fibrinous masses, the size of a small nut, were also present on the raised patches of the endarterium. The aortic valves and heart were normal. In another case, that of a man aged thirty-nine, who underwent an operation on the left thigh, similar changes were found in the aorta. Microscopically, in all the specimens there was to be seen a leucocytal infiltration of the arterial coats, especially about the vasa vasorum. In all the cases there was a source of septic infection. The toxic products of the mycotic growth probably originated the aortitis, the micrococci in the blood finding a suitable nidus for growth in the atheromatous patches. The *cloudy* state of the fibrin was possibly caused by micrococci in a less vigorous state of growth than existed in the arterial coats. The cases were clinically corroborative of Orth's experiments in animals.

The following card specimens were shown:—Mr. Sydney Jones: (1) Malformation of Foot; (2) Peculiarly shaped Calculi. Dr. Sharkey: (1) Meningeal Hæmorrhage; (2) Retroversion of Mitral Valve; (3) Stenosis of Mitral, Tricuspid and Aortic Valves. Dr. Pye-Smith: Cystic Teratoma from an Infant. Dr. C. Turner: (1) Kidneys with Necrosis of Pyramids; (2) Jejunum with Perivascular Hæmorrhages. Mr. Lunn and Dr. Larder: Aortic Aneurysm. Dr. Cayley: Child with large Hairy Mole. Dr. Seymour Taylor: Angiosarcoma of Brain. Mr. E. H. Fenwick: Stone impacted in Prostatic Urethra. Dr. A. H. Robinson: Hypertrophied and Dilated Bladder, with adherent Pericardium.

MEDICAL SOCIETY OF LONDON.

Traumatic Hydronephrosis. — Relation of Tonsillitis to Scarlatina and Diphtheria.

AN ordinary meeting of this Society was held on Monday last, Mr. R. Brudenell Carter, F.R.C.S., President, in the chair.

Dr. LOWE read a paper on Traumatic Hydronephrosis. The patient was a man aged twenty, who was run over by an empty waggon. There was great distension of the abdomen, and ten weeks after the injury a large tumour had formed in the right hypochondriac and lumbar regions. A group of large veins existed over the swelling. There was no hæmaturia after the accident and no evidence of previous calculus. Nine pints of perfectly clear fluid were withdrawn by means of a trocar and cannula; it was of a highly albuminous character. Later still, eight and a half pints were drawn off at a second tapping, and the cyst was injected with a diluted tincture of iodine. The diagnosis of hydatid tumour was also excluded, not only by the albuminous nature of the fluid but by the absence of hooklets, &c. In five of fifteen reported cases of traumatic hydronephrosis the ureter was obstructed by cicatricial tissue resulting from the traumatism. Cases of traumatic hydronephrosis offered a much greater chance of cure by tapping than did hydronephrosis from internal disease. In his own case he believed the ureter had been obstructed by a blood-clot. — Mr. BERNARD PITTS related the case of a girl aged nine, who was admitted into the Hospital for Sick Children. She had been run over by a hansom six weeks previously. There was a large left-sided hydronephrosis, from which forty-one ounces of clear urine having a slight trace of albumen were withdrawn. There was ·14 per cent. of urea in the fluid. Gentle massage retarded somewhat the accumulation of fluid, but a third tapping had to be performed and forty-four ounces of fluid withdrawn. By a more thorough massage carried out systematically the tumour only slightly refilled, and in a few weeks altogether receded so that nothing abnormal could be detected. The child has remained well ever since. In this case Mr. Pitts regarded the obstruction as due to blood-clots in the ureter. In another case related, a child passed casts of the ureter, the casts being clearly of hæmorrhagic origin.—Mr. WALTER PYE narrated the case of a gentleman who received a spear-wound in the abdomen, which was followed by hydronephrosis. Tapping was performed and the case ended in complete recovery. It happened five years ago.—Mr. DAVIES-COLLEY also related a case of right-sided hydronephrosis in a man aged fifty-five, who met with a railway accident. It was probable that the man had had a calculus prior to the accident; there was, at all events, a history of pain and hæmaturia. Massage in cases of traumatic origin might be productive of mischief. He did not think that blood-clot in ureters could be absorbed.—Dr. SAMUEL WEST spoke of the pathology of so-called traumatic hydronephrosis, and considered that some cases might really be instances of retro-peritoneal or peritoneal effusion. —Dr. LOWE, in reply, considered that hæmorrhage from the kidney could easily give rise to clots which would obstruct the ureter. A small hydronephrosis might be partially or totally absorbed. The ultimate result could not always be known; even when cases appeared to be cured fresh effusion might again occur.

Dr. HINGSTON FOX read a paper on Tonsillitis and its relation to Scarlatina and Diphtheria, excluding Catarrh and true (suppurative) Quinsy. The writer first described common, follicular, or septic tonsillitis, giving a group of cases in illustration. This was a brief and symmetrical disease, often affecting several members in one household, and frequently traceable to bad hygienic conditions. Intermediate between this affection and the tonsillitis of the specific fevers lay so-called infectious sore-throat, the pseudo-diphtheritis of Dr. Ashby. The outbreaks recorded in the proceedings of the Medical Society by Drs. Routh and Crisp were shortly described, and reference was made to various other outbreaks reported in recent years. It was suggested that the occurrence of these mixed forms of tonsillitis, often showing a short-lived infectiousness, gives ground for regarding scarlatina and diphtheria as primarily forms of tonsillitis which have acquired specific properties. On this view the poisons would enter the lymphatic system at the tonsils, which would be inflamed as a first effect. The function of the tonsils is, Dr. H. Fox thinks, connected with the reabsorption of the surplus saliva, and it is suggested that these glands absorb the poisons from the saliva. The poison of a common tonsillitis has little more than a local effect; that of a scarlatinal tonsillitis is able to reproduce itself in the system indefinitely without deterioration, and in this power of reproduction Dr. Fox would see the characteristic of a species of disease.

HARVEIAN SOCIETY.

Paralysis of Tongue, Palate, and Vocal Cord.—Treatment of Obscure Forms of Metrorrhagia.

A MEETING of the above Society was held on Thursday, April 1st, J. Hughlings Jackson, M.D., F.R.S., President in the chair.

The PRESIDENT showed a patient who had Paralysis and Wasting of the Right Side of the Tongue, and Paralysis of the Right Half of the Palate and of the Right Vocal Cord. He had recorded several cases in which these three symptoms occurred together (London Hospital Reports, 1864 and 1868). There was also paralysis and wasting of the left supinator longus, biceps and brachialis anticus, deltoid, supra-spinatus, and infra-spinatus: these muscles did not act to the faradaic current; in all anodal closure contraction was greater than kathodal closure contraction, except that the infra-spinatus did not react to forty cells. There was a patch of anæsthesia (to touch and to pain) on the summit of the left shoulder, roughly circular in outline and about six inches in diameter. The eyes were examined by Mr. Marcus Gunn. The left pupil was very slightly larger than the right; there was no difference in the palpebral apertures. The left pupil did not dilate in shade nor react to light (directly or consentaneously). During convergence, which was short and partial, the left pupil contracted as well as the right. Accommodation was defective in both eyes. The left pupil underwent changes in size during ordinary movements of the eyeball, tending to contract on looking downwards or inwards, and to dilate on looking upwards or out-

Digitized by Google

wards. Dr. Wilson, to whom the President was indebted for most of the notes of the case, had twice observed sweating on the left side of the face, a symptom of which the patient complained. Considering that there was a clear history of syphilis and that the symptoms developed slowly, Dr. Hughlings Jackson thought there was syphilitic disease involving nerve roots. He expressed the opinion that the right hypoglossal nerve and the upper (bulbar) part of the right spinal accessory nerve were involved, and also some of the spinal cord nerve roots entering into the left brachial plexus. He had never, with one doubtful exception, seen paralysis of the palate in cases of disease of the portio dura nerve; deviations of the uvula were common in healthy people. He thought that lesion of the bulbar part of the spinal accessory nerve caused the palatal and vocal paralysis. The pupillary condition on the left was not like that occurring with paralysis of the cervical part of the sympathetic, except in that the pupil did not dilate when shaded. According to Ferrier, the particular spinal nerve root supplying fibres for dilatation of the pupil, or for inhibiting the action of the third nerve (Gaskell), is the first, or more probably the second dorsal; but in this case this nerve-root was not implicated, as the intrinsic muscles of the hand were not morbidly affected. Dr. Hughlings Jackson could not explain the pupillary condition; the patient's knee-jerks were present, and he had no tabetic symptoms, unless the left pupillary condition be reckoned as one. Nor could he explain the sweating of the left half of the face, except by supposing that the vaso-motor fibres in the cervical sympathetic arose from higher anterior roots than those supplying the iris.—Dr. S. MACKENZIE observed that he had seen about eight patients suffering with unilateral paralysis of the tongue, soft palate, and vocal cord, and they were of great interest on both anatomical and clinical grounds. The late Dr. Lockhart Clarke had shown the close anatomical union between the nuclei of the hypoglossal and spinal accessory nerves in the medulla, and Dr. Hughlings Jackson had been the first to turn these anatomical investigations to account in elucidating cases of this group. These cases seemed to demonstrate that the palate (levator palati) was innervated by the spinal accessory, and thus a very localised lesion in or outside the medulla explained the simultaneous paralysis of tongue, soft palate, and vocal cord. His own experience confirmed that of the President, that the palate escaped in pure cases of paralysis of the seventh nerve. In two cases he had recently exhibited at the Clinical Society there was also paralysis of the sterno-mastoid and trapezius, indicating that the spinal portion of the spinal accessory nerve was involved. In one of the cases, which, like the President's, was certainly syphilitic, there was no evidence as to whether the paralysis of the sterno-mastoid and trapezius came on at the same time as the paralysis of the tongue, palate, and cord; and, as there was also paralysis of the cilio-spinal fibres on the same side, which arise in the same part of the cord, it seemed probable that the internal and external branches of the spinal accessory nerve were affected by two distinct lesions. But in the second case, the paralysis of the tongue, palate, and cord came on coincidently with the paralysis of the sterno-mastoid and trapezius; and he (Dr. Mackenzie) would like to ask the President what explanation he would afford of such a case, particularly whether he thought a bulbar lesion would account for it. This, of course, would necessitate a close direct anatomical association of the two branches, notwithstanding their apparent difference in origin. He further remarked that in these cases the tongue, as a whole, was scarcely at all deflected to the paralysed side, but the raphe of the tongue was markedly curved, showing that the lateral protrusion of the tongue to the paralysed side in hemiplegia is probably due to other influences than that of the hypoglossal. He further asked the President how he explained in his case the anæsthesia of the shoulder, in the patient exhibited, being on the same side as the muscular paralysis.—The PRESIDENT replied that the disease did not appear to be in the cord itself. He could not explain the anæsthesia.

Dr. ARTHUR W. EDIS read a paper on the Treatment of Obscure Forms of Metrorrhagia. He urged the importance of regarding hæmorrhage merely as a symptom of some constitutional or local disorder, and not as a disease or entity *per se*. It was a conservative effort of nature in many instances to lessen the arterial tension and prevent the occurrence of more serious internal hæmorrhages. A correct diagnosis was the first and most important element of successful treatment, for until the former be known the latter is mere guess-work, and we are as liable to do harm as good in attempting to repress the hæmorrhage. The principle of diagnosis by exclusion was one which approved itself to many—determining, in fact, to what cause the hæmorrhage was not due. This could only be done by knowing beforehand what were the most likely causes of severe hæmorrhage—the *possibilities* so to speak, and then eliminating one after the other until we have left only two or more *probabilities*. Before concentrating attention upon the probable local disorder, the possibility of some complicating constitutional condition, whether cardiac, renal, or hepatic, should always be considered. A clear and concise history of the attack was of great importance in attempting to arrive at a correct diagnosis. Then, again, the colour and consistence of the discharge should be noted: whether bright or dark, fluid or clotted, recent or disintegrated. The duration of the flow, interval between the losses, influence upon the general health, and other similar considerations, should not be passed over. Unsuspected miscarriages and incomplete abortions proved a not inconsiderable percentage of these obscure cases. Some of the most difficult cases to diagnose occurred at or about the so-called climacteric period. Exploration of the interior of the uterus, either by dilating or incising the cervix, should always be resorted to where no sufficient outside cause for the hæmorrhage could be detected. Cases illustrating the difficulty of forming a correct diagnosis were given, and the lines of treatment sketched out. An interesting discussion followed.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Sanitary State of London Poor Districts.

A MEETING of this Society was held on Friday, March 19th, Dr. Corfield presiding.

Dr. LOUIS PARKES read a paper on the Sanitary Condition of Poor Districts in the Metropolis, with especial reference to their Watercloset Accommodation. In introducing his subject, the author brought the following questions forward as being some on which it was very desirable to get an expression of opinion from members of the Society, as a body entrusted with the care of the public health of the metropolis:—1. Is it desirable that the waterclosets of poor-class houses should be flushed by hand with pails of water, or should they be supplied with water from a cistern? 2. Is the law, as it now stands, sufficient to enable a sanitary authority to enforce a supply of water by cistern to a closet which is without one, in all cases and under every kind of circumstance? and is it obligatory on an authority to undertake this duty whenever the fact of a closet being without a water-supply is brought to its notice? 3. If the law is insufficient or too undecided in its terms as regards the powers of the sanitary authority in this respect, or its obligation to enforce the powers with which it is entrusted, what alteration is it desirable to introduce in any fresh legislation on the subject? And with this may be included the consideration of what further powers with regard to watercloset accommodation it is desirable to furnish a sanitary authority with. The danger arising from the situation of closets in underground cellars in tenement houses was alluded to. These dangers were shown to be unnecessarily aggravated in many cases by the closet being without a water-supply, and used—as the only convenience—by all the lodgers in the house, who might be thirty in number, in some of the poorest quarters. A far better arrangement is for the closet to be in the back yard, outside of and away from the house. The "long hopper" closet is the one almost invariably found in use, and it is one of the worst forms; it soon becomes soiled and corroded, and is incapable of being properly flushed. The best form of closet for use by poor people is the "short hopper" of glazed stoneware, with vertical back and sloping front, and with syphon trap below. This form is easily flushed out and kept clean, when supplied with water by a two-gallon waste-preventing cistern. But such waste-preventing cisterns as are supplied to poor-class houses are almost invariably found to be out of order, the ball valve being defective or the outlet valve leaking. The syphon action water-waste-preventer is preferable as being more certain in action, but it is more expensive, and the chains, ball-cocks, and other detachable metallic parts in all these cisterns attract the cupidity of the destructive class of

Digitized by Google

tenants in the poorest quarters, and consequently disappear. Flushing by hand with pails may be made to answer (1) if there is a water-tap in close proximity to the closet in the yard; (2) if the duty of flushing is entrusted to some one person in the house who shall become responsible for its proper performance; and (3) if the sanitary inspector can visit at frequent intervals to see that the flushing is not neglected. In courts and alleys which are not thoroughfares, the author advocated the use of trough-closets in the court, with separate locked compartments or cubicles for the use of each house. These closets can be effectually flushed by a Field's automatic syphon flush-tank, placed in a separate locked compartment, accessible only to the sanitary inspector. These trough-closets have been found in Liverpool and elsewhere to answer extremely well in the case of courts and blind alleys occupied by the lowest and most degraded classes. As to the sufficiency of the law, Section 81 of the Metropolis Local Management Act of 1855 gives power to a sanitary authority to enforce a suitable water-supply and water-supply apparatus to a closet without one, even where no nuisance, as the result of the absence of such fittings, can be proved to exist, and this power relates to houses built before as well as after the Act was passed. The case of Tinkler *v.* Wandsworth District Board of Works, although often cited, has no bearing on this question except indirectly, as here it was a question not of waterclosets but of privies and cesspits unconnected with the public sewer, in which water could not properly be used. It was, however, decided in this case that the local board had power to convert one privy into one watercloset with water-supply apparatus, but could not make a general order to convert any number of privies in their district into waterclosets without exercising discretion in each particular case. In the case of the Vestry of St. Luke's *v.* Thomas Lewis, it was a question of water-closets without water-supply. This case was tried in 1862 in the Court of Queen's Bench. The magistrate's decision adverse to the plaintiffs was reversed, and Lord Chief Justice Cockburn gave judgment to the effect that the vestry had power to order a water-supply to a closet without one. However, it still remains to be decided whether a local authority has power to make a general order enforcing water-supply to all or any number of closets in its district, without exercising discretion in each particular case. The Public Health Act of 1875 empowers a local authority to insist on a "sufficient water-closet" being provided, but there is no clause which deals with the enforcement of a water-supply. "Sufficient" was no doubt intended to include a water-supply. The author pointed out that by Section 7 of the Housing of the Working Classes Act of last session, sanitary authorities in the metropolis now lie under a statutory obligation to enforce in sanitary matters all the powers with which they are provided. It did not appear to be proved that any alteration in the law as regards water-supply to closets was either necessary or desirable, although enlargement of powers for the purpose of providing trough-closets in courts seemed to be needed.—In the discussion which followed, the President, Drs. Seaton, Pringle, Gwynn, Iliff, Dudfield, West, and Messrs. Furnivall, Bernays, Hartt, Cassal, Lovett, and Shirley Murphy took part.

ACADEMY OF MEDICINE IN IRELAND.

Keeping Perforation of the Membrana Tympani open.—The Radical Cure of Hydrocele.—Therapeutic Uses of the Digestive Ferments.—Fetid Expectoration from the Lung.

A MEETING of the Surgical Section was held on Jan. 22nd.

Dr. M'KEOWN (Belfast) described a method of making an Artificial Perforation of the Membrana Tympani which would remain open for a period varying from two weeks to two months. He made a triangular flap of the membrane, commonly selecting either that part in front of, or that behind, the handle of the malleus. He used a speculum, and illuminated the membrane by the frontal mirror. He then introduced the knife—a very fine straight knife with thin handle,—punctured the membrane in front of, or behind the top of, the handle of the malleus, cut upwards as far as he could, then made a second incision, beginning below, either at the anterior or posterior part of the membrane, as the case might be, and in a horizontal line with the lower end of the first incision, and cut upward till the two incisions joined. The flap thus formed, unless in case of very thickened membrane, fell down, or might be turned down with a fine probe, and commonly remained in position, adhering to the membrane below by blood exuded from the cut surface. He had operated on a considerable number of cases—some of long standing,—and he gave particulars of some of the most interesting. The ordinary incisions hitherto practised, except to discharge products of inflammation, were of no therapeutic use whatever. The operation proposed was not for the purpose of making an artificial way for the waves of sound, but to give rest to the ear for a long period, and to induce a nervous and vascular equilibrium favourable to the absorption of deposits and restoration of function. Most troublesome obstructions of Eustachian tubes of long standing had given way to this treatment alone. As to relief of tension in old cases, a simple incision closing in a day or two could do no good, but an opening for a period of from two weeks to two months might do a great deal. Time was the very essence of the question from a therapeutic point of view. He illustrated the use of the method in diagnosis, and also in opening a way for efficient treatment of some cases of hypertrophic change of the lining of the middle ear. So far as he could follow his cases, he found none were made worse, some were not benefited, but the majority were more or less relieved, some to a remarkable extent.

Mr. M'ARDLE read a paper on the Radical Cure of Hydrocele. After describing the methods of Volkmann, Julliard, and Bergmann, he read the notes of three cases illustrating the method of incision. He brought forward specimens to show the ease with which the tunica vaginalis could be removed in the operation for excision. He then compared the methods of injection and dissection chiefly as regards—1st. The relative difficulties of the operative procedures. 2nd. The dangers attending each. 3rd. The length of time required for cure. 4th. The chances of return after each method. In reference to the third point he called attention to the following as the dates of healing. After

Injection.		Incision.		Excision.
Billroth, 9th	...	Volkmann, 8–10th	...	Julliard, 10th
Stoltz, 9–10th	...	Küster, 14th	...	Bergmann, 11–12th
Weiss, 8–9th	...	Lister, 17th		

The chances of recurrence in various methods he stated as follows:—Injection: 315 cases; 41 recurrences. Incision: 238 cases; 5 recurrences. Excision: 72 cases; no recurrences. The percentage of recurrences after injection of different substances seemed to be very much the same: after iodine, 15 per cent.; chloral hydrate, 13 per cent.; perchloride of iron, 11 per cent.; carbolic acid, 10 per cent.; and chloroform, 10 per cent. Mr. M'Ardle recommended the dissection method in: (1) Multilocular hydrocele; (2) hydrocele connected with tubercular testis; (3) cases complicated by mucoid transformation of the cellular tissue of the scrotum; (4) cases where injection of ordinary hydrocele failed more than once; and (5) those cases of hydrocele in which the tunica vaginalis becomes greatly thickened, coated with chalky deposit, or filled with foreign bodies.—Mr. STOKES said he could not, in his own practice, recall a single instance of failure in the radical cure of hydrocele by what Mr. M'Ardle termed the old method of injection, although some of his cases had been injected more than once. In none of the cases was there any serious trouble, such as fever, sloughing of the scrotum, erysipelas, &c.; therefore, he was not disposed to alter his method of treatment for one more hazardous. He had seen Volkmann's treatment by incision, and one of the most important points connected with it had not been mentioned—namely, that having incised the tunica vaginalis, and attached the edges with great accuracy to the edges of the skin by continuous sutures, a series of deep sutures were applied to keep the surfaces in apposition. He had seen serious consequences follow the operation—for instance, retention of urine and fever.—Mr. BARTON said the question was one of choice between the operations which admittedly had certain risks and the well-established procedure which was without any serious risk. He was therefore gratified that Mr. M'Ardle had recommended those operations for the treatment of hydrocele only in difficult cases which had resisted injection.—Mr. CROLY had never known of a single case of hydrocele that resisted the ordinary treatment. Where failure occurred with others, he had no doubt it was due to using iodine in too diluted a form. He never thought of using a solution of iodine and water, but threw in a few drops of undiluted

Digitized by Google

tincture of iodine, which invariably effected a cure. What he advised was to dip the probe into a little bit of lard and then wipe with red precipitate. A few grains of red precipitate introduced into the tunica vaginalis, or a few drops of tincture of iodine, would effect a cure in ninety-nine cases out of a hundred. By this means he would leave nothing to be cut out. He never saw gangrene, erysipelas, or anything bad follow the operation; or, if there did, it was the fault, not of the operation, but of the operator.

At a meeting of the Medical Section on January 29th,

Dr. PURSER read a paper on the Therapeutic Uses of the Digestive Ferments, in which he condemned as useless and irrational the internal administration of these substances, and argued that their true use in medicine was limited to the preparation of artificially digested food.—Dr. HENRY KENNEDY took exception to Dr. Purser's observations about the effect of pepsine, of which he had had favourable experience himself in children, with whom imagination could not be said to operate. How pepsine acted he was unable to explain. Some preparations of pepsine with glycerine were calculated to develop an unpleasant smell, which made it disagree.—Dr. WALTER G. SMITH regarded Dr. Purser's conclusions as founded on incontrovertible data. It was high time to protest against the illogical and irrational mode of using so-called aids to digestion.—Dr. J. W. MOORE said that rectal alimentation was one of the principal uses of digestive agents, from the addition of which to nutritive enemata he had seen good results.—Dr. ATTHILL said he was sure Dr. Purser's remarks were based on scientific principles, but possibly some of his deductions were not strictly correct; because experiments carried on outside the body could not be identical with experiments inside. While sensible that there was a vast amount of humbug in the sale of digestive ferments, he did not agree with Dr. Purser that those ferments were absolutely useless, having himself prescribed pepsine with good results, especially in the case of children and delicate women. In artificial feeding per ano the peptonised food was of the greatest importance.—Dr. PURSER replied that he was prepared for the protest made as to the use of pepsine, and had anticipated the objection in his paper. As to the effect of medicine on children and delicate women, he did not say the effect was produced through the imagination; but he did not know anybody who gave pepsine and nothing else. The diet was always regulated to make it more easily digestive, and pepsine was prescribed with acid or aromatic water, and aromatic water would often cure gripes in children. To say the thing was different inside the body and outside the body showed an erroneous conception of digestion, which did not take place inside but outside the body. The mucous membrane of the stomach was just as much outside the body as the palm of the hand. The preparations for rectal alimentation were of some value.

Dr. H. KENNEDY detailed two instances, both in young females, where a very profuse expectoration, attended by a most offensive odour, occurred. The fetor was so great as to diffuse itself through a large ward, like what occurs in gangrene of the lung. The physical signs were in each case confined to one lung, and were what is now known as chronic strumous pneumonia. In each case there were slight signs of hectic, with the nails curved; whilst menstruation was irregular. Under the use of a combination of powdered uva ursi and charcoal the patients improved much in their general health, and the fetor quite ceased at the end of ten days, and in about a month each patient left the hospital to look for places as servants. No local treatment in the way of inhalation was used.—Dr. HAYES instanced the case of a woman in Dr. Steevens's Hospital whom he had seen at the request of a colleague; the patient was the subject of a fetid bronchitis. He suggested an inhalation consisting of a combination of creasote, carbolic acid, iodine, and spirit, and the fetor disappeared entirely in a few days.

CHESTER MEDICAL SOCIETY.

A MEETING of this Society was held on Friday, February 5th, Mr. James Taylor, F.R.C.S., President, in the chair.

Small Mitral Valve.—Mr. H. DOBIE, on behalf of Mr. George Harrison, exhibited a heart, the mitral orifice of which barely admitted an ordinary black lead pencil. The other valves were healthy, but there was fatty degeneration of the organ. The patient was a woman of forty years of age, giving no history of rheumatic fever. Her pulse averaged forty-eight beats per minute, but no murmur was discoverable during the ten weeks she was in hospital.

Syphilis.—Dr. WEAVER (Frodsham) read notes of a case of Syphilis which he had observed through its various phases for two years. One marked symptom had been severe neuralgia in both temples coincident with periostitis of the vertex excited by a blow. Dr. Weaver asked what remedy had in the experience of members been found most effectual for this bi-temporal neuralgia, when gelsemium, bromide of potassium, and iodide of potassium, together with a long mercurial course, proved ineffectual.—Dr. DOBIE said he had recently seen a case in which gelsemium had failed yield at once to a course of perchloride of mercury with iodide of potassium. These he thought the best remedies for the neuralgia of syphilis.—Surgeon-Major TOMLINSON thought that when these means failed the hypodermic injection of morphia should be had recourse to.

Mr. ALEXANDER BARRON of Liverpool (visitor) exhibited a Microscopic Section of a Primary Desquamating Syphilitic Papule, showing lymphatic spaces containing a hyaline coagulum, in which multitudes of micrococci were embedded. He explained the staining reaction of the organism and the difficulties in its cultivation. He had found it in glands secondarily affected and in tertiary lesions of recent development. He thought it could always be found in syphilitic lesions if looked for at the proper time, and that, considered in the light of our knowledge of the pathology of tubercle and other allied diseases, the probability of its being the cause of the disease was very great.—Mr. STOLTERFOTH thought the detection of the bacillus might often form a valuable aid in the diagnosis of syphilis.

Dr. WATERS read a paper on the Communicability of Typhoid Fever, the discussion upon which was postponed.

At the meeting on March 5th, Mr. MILLER showed a specimen removed from the body of a labouring man, aged fifty-one, who had been under Dr. Stolterfoth's care in the Chester Infirmary. A firm pulsating tumour, with a distinct murmur to be detected by auscultation over it, was discovered situated behind the right sterno-clavicular articulation. A few hours before death great dyspnœa came on, and expectoration of mucus tinged with blood. The post-mortem examination disclosed a sac, bounded apparently by the surrounding tissues, without arterial coats, containing broken-down coagulum. This sac communicated on the one hand with the right carotid artery, which was atheromatous, by a minute aperture, and on the other with the œsophagus and the trachea, the former by a very free opening.

Mr. TAYLOR showed an Ovarian Cyst recently removed by him with success in the Chester Infirmary. Mr. Taylor also exhibited a piece of intestine removed (post mortem) from a case of obstruction of the bowels. This he handed over to the Pathological Committee for examination.

Measles.—Dr. HAINING read a note of five cases of measles which he had had the opportunity of personally observing closely, proving that measles is infectious in the stage of catarrh, and pointing to nine days as about the average length of the incubation stage.

Dr. DOBIE showed a beautifully designed and coloured Temperature and Pulse Chart of a case of Typhoid Fever, observations having been recorded several times each day by the husband of the patient.

Hæmophilia.—Mr. Moreton of Tarvin read a paper on Hæmophilia, giving details of a series of cases in one family of which he had had the care. The mother appeared to be the source of the mischief, but was not herself a "bleeder" and showed no tendency to post-partum hæmorrhage at any of her confinements. The eldest son was not a bleeder, but suffered when young from most obstinate dyspepsia, at one time weighing only 63 lb., while he was 5 ft. 9 in. in height. He is now alive and in good health in Virginia. The second boy, after frequent attacks of bleeding, died at the age of ten from epistaxis. The third, fourth, and fifth boys died between the ages of three and eight from hæmorrhage. The sixth died at eighteen months from bleeding from the mouth, without apparent injury. None of the girls were "bleeders." The mother had had four abortions, and in every case the fœtus was a male. Mr. Moreton frequently examined the blood of these patients, and always found it normal as regards coagulation and microscopic appearance.

Digitized by Google

He thought a peculiarity in the structure of the capillaries would best explain the condition, but he believed it was open to anyone to start a new theory as to the real nature of the conditions which result in the disease.

A discussion followed, in which several members gave their experience of more isolated cases.

MIDLAND MEDICAL SOCIETY.

A MEETING of the above Society was held on Wednesday, March 3rd, Dr. J. Holmes Joy, President, in the chair.

Lead Tremor.—Dr. SUCKLING showed a man, a lapidary, who had suffered for years at times from lead colic. A week before coming to the hospital he noticed trembling of the hands, which came on somewhat suddenly and obliged him to give up work. There was marked rhythmical tremor of the hands and forearms on extension, ceasing during rest; also, wasting of the thenar muscles and some weakness of the extensors of the wrist. There was a well-marked blue line on the gums.

Brass-founder's Ague.—Dr. SUCKLING showed a man who had worked in brass for twenty-six years. The casting shop was immediately under the room in which the man worked, and whenever any casting was done the dense fumes given off always made him ill, causing shivering and sweating, very frequently also vomiting, pains about the chest and limbs, and broncial catarrh. The man had a well-marked green line on the teeth close to the gums, and his hair was of a greenish tint. Dr. Suckling met with the disease very frequently among the out-patients at the Queen's Hospital, and he found that iodide of potassium gave relief.

Amblyopia and Monoplegia.—Dr. SUCKLING showed a child with Paralysis of the Right Hand and Amblyopia. Several months previously it had been seized with vomiting followed by Jacksonian epilepsy, the convulsions always beginning in the right hand and then passing on to the right side of the face, then to the right leg. Three months ago the convulsions ceased to occur, but the right upper extremity remained paralysed and had become rigid. Latterly the child had lost its sight, running into objects and not recognising its parents. The pupils responded normally, and there was no change in either fundus; there was a marked history of phthisis on the mother's side. Dr. Suckling considered that the monoplegia indicated mischief in the convolutions around the left fissure of Rolando, and that the amblyopia was due to extension backwards and implication of the angular gyrus, and possibly also of the outer surface of the occipital lobe.

Aortic Aneurysm.—Dr. CARTER showed a specimen of Aneurysm of the Ascending Aorta, taken from a miner aged thirty-six. There was no previous history of rheumatism, syphilis, or chronic alcoholism, and the lesion was attributed to chronic aortitis occurring in connexion with over-strain of the heart in the course of his work. The tumour pointed externally to the left of the sternum, between the second and fourth ribs. In the early stage great benefit was derived from Tufnell's plan of treatment. Later on, when all other treatment had failed, and the aneurysm threatened to burst externally, galvano-puncture was performed, and for a month after this there was great improvement; but the symptoms returned, and finally death took place from hæmoptysis, due to encroachment of the aneurysm on the tissue of the left lung. The total duration of the illness was about sixteen months.

Spinal Curvature.—Mr. WILLIAM THOMAS exhibited two patients suffering from Angular Curvature of the Spine, each of them wearing an inexpensive jacket which he desired to bring before the members of the Society as a useful method of treatment. The principal feature of the jacket was a support of soft Swedish iron, which could easily be adapted to the changing shape of the spine, and could readily be arranged to support the head. This was applied closely to the spine, and, being sewn into a jacket of jean, was kept in position by lacing up the front. He claimed for it greater facility of application, more ease to the patient, less cost, and better results than from treatment by the plaster jacket.

Mr. JORDAN LLOYD showed a Hernial Sac that he had removed from a child, and another from a man aged twenty-nine; this latter contained a quantity of omentum. The result in both cases had so far been satisfactory.

Dr. MALINS showed a dumb-bell-shaped Ovarian Cyst containing a number of papillary growths.

Mr. HASLAM showed a Ruptured Liver and Right Kidney due to a kick on the abdomen from a horse. The patient, a man aged twenty-nine, had no symptoms indicative of a serious lesion until after five days; he was then seized with shock and collapse, his abdomen became distended, and there was suppression of urine; he died after twenty hours. At the post-mortem examination about half a pint of blood was found in the peritoneal cavity; this probably came from the damaged under-surface of the liver.

Mr. LAWSON TAIT read a paper on four cases of Chronic Inflammatory Disease of the Uterine Appendages.

Reviews and Notices of Books.

The Causes and Prevention of Blindness. By Dr. FUCHS, Professor of Ophthalmology in the University of Liège. Translated by Dr. R. E. DUDGEON. Pp. 247. London: Baillière, Tindall, and Cox. 1885.

THIS work is the outcome of a prize offered by the Society for the Prevention of Blindness in London at the Fourth International Congress for Hygiene, which met in September, 1882, at Geneva. The volume is divided into nine parts, as follows: eye diseases of hereditary origin, eye diseases of childhood, eye diseases incidental to the educational period, eye diseases consequent on general diseases, infectious eye diseases, influence of occupation on eye diseases, influence of social conditions on eye disease, influence of climate and race on eye disease, and, lastly, treatment of eye diseases. Perhaps the most interesting of these divisions is that which relates to the eye diseases incident to the educational period, and which of course treats at length of the development of myopia. Many points are here discussed, and many rules laid down that are wholly ignored in English schools. To mention only a few. How rare is it to find an architect who, in building a school, pays the least attention to the light. Yet this has been the subject of careful research by many German writers. Almost all are agreed that the windows should look towards the east and the south-east. There are advantages, however, about the south which should not be overlooked. Rooms so lighted are much more cheerful and wholesome; they are warmer, and the excess of light in summer, which is hardly to be dreaded in this climate, can easily be guarded against by blinds. The position of the windows should not be overlooked. Light should, if possible, be admitted chiefly or altogether from the left, and skylights always afford excellent illumination. The proportion of window superficies to floor superficies is given by the best authorities at from 1 : 8·6 to 1 : 1. In Brunswick an inspection of the schools showed that three-quarters of them were insufficiently lighted. In the evening, when artificial light is required, there should be one burner to every four scholars. We should like to know the proportion in most private and in several public schools; we fancy one burner to ten scholars would be nearer the mark. In Liège several of the schools are lighted by electricity. When will this be carried out at Eton, Harrow, Rugby, Westminster, Winchester, and Shrewsbury? Then the subject of the seats and desks is of the greatest possible importance. Dr. Fuchs says: "The scholar sits in a proper manner when the upper part of his body is straight, so that pelvis and shoulders are parallel to the border of the desk, and the head is erect or slightly bent forwards. The feet should rest upon the floor, the back supported by a sacral rest. When writing, the forearms, but not the elbows also, should rest on the desk." An indispensable requisite for this posture is a properly constructed seat. In an appendix to Dr. Fuchs' work Dr. Roth gives some good illustrations of good and bad positions in writing and drawing. Great interest attaches to the questions of the character and slope of writing, and to the features of the print children have to employ. Dr. Fuchs does not

Digitized by Google

believe the German character to be so injurious to the eyes as is generally believed. In regard to age, no child under six should be admitted into school. For the lower classes the maximum for "sitting lessons" should be three and for the upper four hours. He compares the number of hours which the scholar has to give to lessons and to play between his tenth and nineteenth year in Germany, France, and England. They are as follows:—In England, working hours 16,500, play 4500; in France, work 19,000, play 1300; in Germany, work 20,000, play 650; and to this excess of work in Germany he attributes the prevalence of myopia in that country. Dr. Fuchs would cut down the time devoted to the dead languages. There is a valuable section on the purulent ophthalmia of new-born children, in which the importance of prophylaxis, both as regards mother and child, is strongly insisted on. The author approves of Credé's plan of dropping a weak solution of nitrate of silver into the eyes of the infant. The subject of trachoma, so frequent abroad, though happily rare in this country, is fully discussed. The book is well got up, and is a valuable addition to ophthalmological literature.

Clinical Lectures on the Practice of Medicine. By the late ROBERT J. GRAVES, M.D., F.R.S. In Two Vols. Vol. II. London: The New Sydenham Society.

WE have now to notice the appearance of the second volume of these Clinical Lectures, so creditable to British medicine, and so indispensable to every practitioner who would have a well-furnished mind, not to say library. Not that all Graves's theories, either of therapeutics or pathology, can be now sustained. He lived before the great revolution in practice which has resulted from a truer estimate of the part of nature and of art in the treatment of disease, though there are many indications that even in regard to the errors of the old practice he was in advance of his contemporaries. But, allowing for these, Graves must still be greatly read and respected by every intelligent practitioner. His range of practice was so wide, his attention to particular cases and details of cases was so admirable, his eye for therapeutics and the benefit of the patients was so keen, his resources and suggestions so original, and he was withal so reasonable—so physiological—in his pathology, that he will always stand out as a model physician. No disease was too vulgar for his study, no remedy too humble for him to consider. He treats of headache, of diarrhœa and constipation with as much orginality and interest as he does of exophthalmic goitre. His classical lectures on these subjects will be found in this volume, for which we have to thank the New Sydenham Society.

Essentials of Histology, for the use of Students. By E. A. SCHAFER, Jodrell Professor of Physiology in University College, London. Pp. 244; 281 Woodcuts. London: Longmans. 1885.

THIS work is divided into forty-two sections, chapters, or, as Mr. Schäfer prefers to call them, lessons. Each lesson, as the size of the book renders evident, is short, and is illustrated by several woodcuts; many of the woodcuts are taken from the histological portion of the last edition of "Quain's Anatomy," which Mr. Schäfer has had so large a share in editing; others come from the author's own stores, or from some well-known text-book. To show the method pursued by the author we open the book at random at the twentieth lesson. This treats of the structure of the larger blood-vessels. It commences with directions for five experiments, which the student should make for himself—viz., sections and staining of a medium-sized peripheral artery and vein; the demonstration of the endothelium; the demonstration of the other tissues by teasing and staining; the comparison of the structure of a large with that of a small artery and the structure of a vein; then follows a description of the structure of vessels, illustrated with seven woodcuts. Mr. Schäfer has had so much experience in teaching, and is recognised as so good a teacher, that it is unnecessary for us to say a word in regard to the letterpress. It is less full than Dr. Klein's admirable little volume on Histology, but it contains all that a student of histology, physiology, or pathology needs to know.

The Two Foundations of St. Bartholomew's Hospital: A.D. 1123 and A.D. 1546. By W. MORRANT BAKER, F.R.C.S., Surgeon to the Hospital. London: Smith, Elder, and Co. 1885.

THIS little book contains the substance of an introductory address delivered before the Abernethian Society at the first meeting of the session 1885–6. Specially interesting as it must of course be to all who can boast that they are *alumni* "of the oldest hospital in London," it possesses also general interest for all who are curious in the antiquarian history of our great medical charities. Interesting quotations are given, in the quaint old spelling and phraseology of the period, from a manuscript in the British Museum devoted almost entirely to the life and acts of the founder (more than seven centuries ago) of St. Bartholomew's Hospital—one Rahere, or more correctly Rayer. The author remarks that Rahere is often referred to as the King's minstrel, or even his jester, but that there is no good reason for believing that he ever held any official position in either capacity. Be that, however, as it may, he seems, in order to accomplish his good object, to have been like one of Shakespeare's immortal jesters, "wise enough to play the fool." In the words of the manuscript, "he made and feigned himself unwise, for he was so coacted and outward pretended the cheer of an idiot, and began a little while to hide the secretness of his soul; and the more secretly he wrought, the more wisely he did his work." Socialists, and other too perfervid and reckless agitators, may congratulate themselves that a hospital is more of a sanctuary than it was in the days of Richard II., when Wat Tyler, being wounded by the mayor, William Walworth, and subsequently conveyed "into the hospitall of Saint Bartilmewe," the mayor "went straight thither, and made him to bee carried into Smithfield, and there caused him to bee beheaded, his head to bee set on a pole, and borne before him to the King, then remayning in the field; and the King caused it to be borne neere unto him, therewith to abash the Commons, greatly thanking the Mayor for that acte." It is interesting to note that at the time of the second foundation the annual income of the hospital was about £800; in 1837, £30,000; and last year £60,000. The frontispiece of this interesting little work—which, by the way, is tastefully got up and clearly printed—is a reproduction of a portion of an engraving contained in the *Vetusta Monumenta* of the Society of Antiquaries.

Chemistry, General, Medical, and Pharmaceutical; including the Chemistry of the British Pharmacopœia. By JOHN ATTFIELD, F.R.S., Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, &c. Eleventh Edition. Van Voorst. 1885.

PROFESSOR ATTFIELD'S manual is so well known that an eleventh edition would scarcely call for notice if it were not for one important improvement—viz., a well written and remarkably lucid section on systematic organic chemistry, in which the modern classification is explained and all the chief groups discussed in some detail. So far is this from interfering with the practical character of the book, that it renders the experimental study very much easier. Without the classification derived from theory organic chemistry is a hopeless labyrinth of isolated facts, for the remembrance of which no human memory would suffice. Professor Attfield adopts an arrangement which is perhaps

Digitized by Google

on the whole, the most convenient—taking first hydrocarbons and their derivatives, then the acid compounds, and so on. Few important groups are omitted in the classification, but it might have been wise to have given a general description of the amides and osmic acids, most of which are, however, described in appropriate places. On the whole, we are inclined to think, from its clearness, practical character, comprehensiveness, and enormous index, that no treatise on chemistry at present extant is likely to be as generally useful to medical men and medical students as that of Professor Attfield. To pharmaceutists it is of course essential.

New Inventions.

THE LENIMOR: A POCKET INHALER.

WE have received a small instrument, in shape resembling an enlarged cigarette-holder, about three inches long, which has been invented and patented as an inhaler. It is made of ivory, is very simple in its construction, and can be carried in the waistcoat pocket and made available for use at any time. All that is needed for the purpose in view is to place a pledget of wool soaked in the medicament—e.g., eucalyptol or turpentine—within the tube, the free extremity of which is then closed by a cap. Air is admitted by two small apertures below the cap, and the aperture at the mouthpiece is also of small size. By using the instrument in the manner of a pipe, the patient inhales the vapour quite as effectually as if he were wearing the less sightly oral inhaler. The inventor, who is a sufferer from lung disease himself, has found relief from its use; and we may add that we have tested it upon a patient, who stated that it was as effectual as the ordinary inhaler. We question whether in most cases the vapour has more than a local action upon the pharynx and upper larynx, but at any rate the idea is ingenious and the instrument worthy of trial.

DR. SPENCER'S IMPROVED BINAURAL STETHOSCOPE.

THE features peculiar to this stethoscope are the communication between the metal tubes or ear-pieces, which is made by means of a short transverse junction that serves also as a hinge; so that when in use the two curved ear-tubes cross one another, a red rubber band below the hinge serving to maintain the requisite degree of pressure to keep the stethoscope in position. The two flexible tubes, to which either a single chest-piece or two separate chest-pieces can be attached, if, as in the latter case, it is intended to convert the instrument into a differential stethoscope, are so constructed as to be detachable from the metal tubes, thus enabling the physician to carry the instrument with great convenience. We have had frequent opportunity for testing the stethoscope in consultation, and can assert that its conducting powers are very good. It is equally excellent whether used as a single or differential stethoscope. How far the open junction between the two tubes aids in reinforcing the sound we can hardly say, but at any rate the instrument is ingeniously devised and admirably constructed. It is made by Ferris and Company, Bristol.

SOCIETY FOR THE STUDY AND CURE OF INEBRIETY.

THE annual address by the President, Dr. Norman Kerr, delivered on Tuesday last, was on the Legislation needed for the Habitual Drunkard. The President called attention to the contrast between the United States and England. In the former country the poorest inebriate could be treated at a State-supported home for inebriates for six months, while in the latter there was no provision whatever, under the Habitual Drunkards Act, for the destitute or for persons of limited means. Only the well-to-do could avail themselves of the provisions of the Act. Truly, here was one law for the rich and another for the poor. Some homes had been very unsatisfactory, and confirmed, rather than cured, the inebriate habit. These injured the character of even genuine homes, of which the Dalrymple Home was the chief, it being the only licensed retreat conducted without financial benefit to the proprietary, and which published its returns in a scientific form. The Act should be improved and be made a permanent measure. As the appearance before two justices acted as a deterrent, this forbidding procedure should be abolished; and (as in the United States) a confirmed inebriate ought to be allowed to sign away his freedom and enter a retreat on a simple contract with the licensee. Any abuse of the liberty of the subject could be effectually prevented by inspection, visitation, and power of appeal by the patient. Escaped patients ought to be taken back direct to the home without the punitive ordeal of having to appear before a justice, as at present. There should also be provision made, at the public cost, for the poor and for such as could afford to contribute only a little towards their sustenance and care. Magistrates, too, ought to have the power to compel the entrance of certain well-defined cases of inebriety into a retreat.

Dr. J. B. HURRY (Reading) read a paper on Uncontrollable Inebriety.

ANTIPYRIN IN PERNICIOUS FORMS OF MALARIAL FEVERS.

To the Editor of THE LANCET.

SIR,—Whilst in charge of the Police Hospital of Bombay during my tenure of office as Acting Police Surgeon I had considerable opportunities of testing the effects of different kinds of treatment in malarial fevers, of a remitting as well as of an intermitting type. In common with most men who have had much experience of these fevers, I met many cases of a remittent type which were not amenable to the ordinary treatment, whether by quinine, arsenic, or diaphoretics with aconite. I determined to try the effect in such cases of administering antipyrin in sufficiently large and repeated doses, to ensure a reduction of the temperature to the normal standard. The result was most satisfactory, so much so that during the last five months of my tenure of office I found no case that was not amenable to this treatment. Many cases that for weeks had been quite unaffected by the ordinary remedies were instantly cured by the exhibition of antipyrin followed by quinine. The few cases in which I found the effects unsatisfactory eventually showed other complications, such as abscess of the liver or phthisis. I am of opinion that in pernicious forms of uncomplicated remittent fever we have a most valuable aid to treatment in antipyrin.

As I am not aware that this treatment has been advocated in the malarial fevers of the tropics, I write to give you the result of my experience, in the hope that it may prove of use to those who have to contend with this common and only too fatal disease.—Your obedient servant,

Sheffield, April, 1886. JOHN HOPE POTTER.

DEGREES FOR LONDON MEDICAL STUDENTS.

To the Editor of THE LANCET.

SIR,—Apropos of the letter signed "Justice" in your last issue, can you or some of your readers give any information regarding the proceedings of the Joint Commission of the two Colleges appointed to consider this question? I trust that the matter will not be shelved, but that if nothing is to be done we shall be told so without further delay; if, on the other hand, there is a prospect of the early removal of this fruitful source of heartburning amongst us, the sooner some intimation is given to that effect the better for the Colleges themselves. The season for "Brussels" is now coming round again, and many an English student may be deterred from deserting the metropolitan schools in favour of a degree-giving northern University by a timely announcement before his arrangements are made for the ensuing summer session.

I am, Sir, yours truly

April, 1886. FAIR PLAY.

Digitized by Google

THE LANCET.

LONDON: SATURDAY, APRIL 10, 1886.

WE are now free to notice the new Medical Bill, which, by the courtesy of the Government, we have had before us for some weeks. Whether it is a good Bill, and what are its chances of passing, we shall leave for consideration at another stage of this article. Our first care shall be to give our readers some idea of its main provisions. We shall then be in a better position to consider its chief faults and defects.

The Bill is divided into three parts. Part I. has reference to Admission to Medical Practice and the Constitution of the General Council, and contains ten sections; Part II. has reference to Colonial and Foreign Practitioners, and includes seven sections; Part III. contains Miscellaneous Provisions, and contains seven sections. Part I. is the portion of the Bill in which members of the profession and those who contemplate entering the profession will be most interested, and it is chiefly the sections of this part of the Bill which we have to analyse.

Qualifying examinations, which after a certain day are to entitle to registration, are to be in Medicine, Surgery, and Midwifery; and a qualifying examination is to be in these three subjects, and to be provided either by the General Council or held by any of the following bodies—(*a*) Any university in the United Kingdom for the time being capable of granting such diploma or diplomas; or (*b*) any combination of two or more corporations in the same part of the United Kingdom who may agree to hold a joint examination; or (*c*) any combination of any such university as aforesaid with any other such university or universities, or of any such university or universities with a medical corporation or corporations, the bodies forming such combinations being in the same part of the United Kingdom. The standard of proficiency is to be such as to guarantee sufficient knowledge and skill for the practice of the three branches of the profession. It is to be the duty of the General Council to maintain such standard of proficiency, and for this purpose to appoint a number of inspectors to attend at all or any of the qualifying examinations held by any of the aforesaid bodies. The appointment of inspectors is to be sanctioned by the Privy Council. Inspectors appointed under the Bill are not to interfere with the conduct of any examination, but it shall be their duty to report to the Medical Council their opinion of the sufficiency or insufficiency of such examinations. The General Council is to forward a copy of such reports to the bodies which held the examination and to the Privy Council. Inspectors of examinations are to receive such remuneration as the General Council may determine, with the sanction of the Privy Council. Section 4 provides that if at any time it should appear that "the standard of proficiency required from candidates" at the qualifying examinations is insufficient, the General Council shall make a representation to that effect to the Privy Council, and the Privy Council may, by order, declare that the examinations of any such body or bodies shall not be deemed to be qualifying examinations for the purpose of registration; and the Privy Council, on the representation of the General Council, or of their own motion, shall have power at any time to revoke any such order. During the continuance of such an order the examining body in fault is not to have a representative in the General Medical Council. Section 5 provides that under the circumstances described in Section 4 the General Medical Council may hold qualifying examinations in any part or parts of the United Kingdom, providing for the appointment of examiners, the nature and conduct of the examinations, &c., provided that no candidate be excluded on the ground of adopting any particular theory of medicine, and that provision be made for the admission of women; or the General Council, subject to "the sanction and control of the Privy Council," may combine with any one or more of the bodies, and examinations so held are to be regarded as qualifying examinations. Expenses incurred by the Medical Council in the discharge of such examining duties are provided for in a subsection. Section 6 defines the privileges of a registered medical practitioner—viz., that he shall be entitled to practise Medicine, Surgery, and Midwifery in the United Kingdom and (subject to any local law) in any other part of Her Majesty's dominions, and to recover charges, expenses, fees, &c.

The constitution of the General Council is dealt with in Sections 7, 8, 9, and 10. The members of the Council are to number twenty-eight—i.e., six Crown members, four members chosen by registered practitioners, seven by the examining bodies in England, six by those in Scotland, and five by those in Ireland. Most of the bodies, including the Apothecaries of England and Ireland, are to continue to enjoy a representative all to themselves in the Medical Council; the exceptions are that the Durham and Victoria Universities are to have one between them in England; the Universities of Aberdeen and St. Andrews one between them in Scotland; the Universities of Edinburgh and Glasgow each receiving a representative. The representatives in the General Medical Council of the registered practitioners shall be also members of the Branch Council of their particular division of the kingdom. The president of the Council, by Section 9, must be chosen from the Council. Section 10 makes provision for the revision of the constitution of the Medical Council at any time by Her Majesty by an Order in Council, where Parliament does not object: the particular cases contemplated being new universities worthy of being represented in the Medical Council; or bodies having at first only collective representation, and so growing in importance as to deserve separate representation; or constituent bodies so diminishing in importance as not to be entitled longer to representation in the Medical Council.

We need not dwell here on Part II., which has reference to the admission of colonial and foreign practitioners to separate lists in the Medical Register on the strength of certain diplomas satisfactory to the General Medical Council, save to notice Section 13, which provides that a person holding a colonial or foreign diploma not recognised by the General Medical Council may appeal to the Privy Council, and that the Privy Council may then order the General Medical Council to recognise such diploma.

Part III. of the Bill empowers the Privy Council to take action, in default of the Medical Council, in respect of

Digitized by Google

inefficient examinations, and provides that any two or more Lords may exercise the powers it confers on the Privy Council. It contains a clause securing the existing privileges of all practitioners now registered, and other miscellaneous and less important clauses.

The analysis of the Bill leaves us little space for criticism to-day. We cannot say that it is a Bill which rouses our enthusiasm. True, it concedes four direct representatives—but only by a gross process of addition to a Council, already far too large, where they would be hopelessly outvoted and outnumbered by the representatives of corporations and universities. The Bill deals timidly with the great questions of Medical Reform. It shirks them. It does not directly or materially reduce the number of licensing authorities. It does not reduce, but increases, the size of the Medical Council. There is an unpleasant assertion of the Privy Council in the Bill, as if the Medical Council would not be able to appoint an inspector or to pronounce on the efficiency of an examination without the sanction of the Privy Council. And in the foreign and colonial part of the Bill it is actually provided that the Privy Council, on appeal by a foreign graduate, may override the Medical Council and order it to recognise a foreign diploma of which it does not approve. It almost reads as if the Bill meant to provide powers for the Privy Council to supersede the Medical Council. There is much in the work and constitution of the Medical Council to have provoked such an effort on the part of the Government. But it ought to be possible to construct a Medical Council which might be trusted with full powers to govern medical education. The Bill gives the Medical Council no power of supervising examinations for higher titles. It makes no attempt to strengthen or simplify the penal clauses of the Medical Act, though from every large town the constant fraud of unqualified practice is reported. It is no doubt important to provide for the admission of foreign and colonial practitioners, and even to define the terms on which women are to be admitted to the profession. But these are objects infinitely less important than a sound and courageous reform of the Medical Council and the licensing bodies, and a proper provision of means for protecting the public from false and fraudulent practitioners.

THE magazines and newspapers have lately been discussing at great length the attractive topic of the choice of reading, and the merits of the best hundred books which the world has hitherto produced. However interesting and suggestive such a discussion may be, its value is largely undermined by the consideration that the mental aptitudes and intellectual needs of individuals are as varied as their physical features, and cannot be adequately met by any process of arbitrary selection. We do not choose food for the body with a view solely to obtaining the maximum of the nutritive elements. Experience teaches us that we must have regard to individual taste and individual need, and that digestibility and assimilability are more necessary qualities in our food than the possession of the greatest amount of carbon and nitrogen. A similar principle must regulate the choice of intellectual food if we would secure intellectual growth and avoid intellectual dyspepsia. PLATO and SPINOZA are no more suitable to every mind than cheese and beef essence to every stomach.

In the discussion to which we refer, attention has been directed rather to systematic than to desultory reading, to profit rather than recreation. Yet literature fulfils one of its noblest ends when it simply refreshes the jaded brain-worker, and reanimates him for fresh intellectual effort. Amusement and distraction are among the prime necessities of our nature, and can nowhere be more easily and innocently obtained than in following the devious plot of the novelist, or smiling at the sallies of the satirist, or watching the luminous sparkle of the poet's fancy. The garden of universal literature lies open, decked with a countless variety of hue and exhaling an infinite diversity of odour, and we need but to train the eye and cultivate the sense in order that we may enjoy its fragrance and taste of its sweetness. In teaching us what to read and how to read education fulfils one of its most necessary objects. It furnishes us with the passwords by which we can traverse the barriers of time and space, and enjoy the intellectual treasures of every race and every age.

No men need recreative reading more than medical practitioners, or are more likely to derive from it the peculiar form of intellectual distraction which they require. The absorbing character and scanty leisure of medical life are hostile to the cultivation of tastes and accomplishments which call for prolonged application; but the daily duties of the average practitioner involve very little bookwork, and in books, therefore, he can find that relief and variety which constitute the most essential features of the rest and solace so loudly demanded by the overtaxed brain. The barrister, clergyman, politician, or author, whose daily work involves a frequent reference to books, cannot take down a favourite volume with the same zest and freshness as the medical man who has been engaged during the day solely in the contemplation of disease. Books have a further recommendation to the busy practitioner. They can be taken up or laid aside at will; they can be carried in the pocket and enjoyed during the casual moments of leisure; they serve to distract the mind without in any way unfitting it for renewed application to the problems and duties of the hour; they are the only friends who are always present when their presence is grateful, always conversable when converse is desired, yet absent or silent when absence is welcome or when silence is golden.

In suggesting the choice of recreative reading to medical men, we would guard against the error to which we have above drawn attention—the error, namely, of laying down specific rules in a case where everything depends upon individual taste and individual training. History, philosophy, poetry, and fiction have each their place and their value, which cannot be adjudged according to any absolute and abstract standard, but vary with variations in intellectual taste and capacity. We think, however, we are safe in affirming one general rule—viz., that more true solace and abiding satisfaction are to be obtained from the loving and repeated study of some great classic than in the perusal of the ephemeral literature of the day—"wet," as Mr. RUSKIN describes it, "with the latest spray of the fountain of folly." The practitioner who carries about with him a well-thumbed "Homer" or "Horace," or a "Shakespeare"

Digitized by Google

or "Goethe" soiled with stains honourable alike to poet and to reader, possesses a talisman of unfailing potency to relieve weariness, and to sweeten the worries and annoyances of his career. Another, to whom poetry is as a casket sealed, can revel in the fruits of SCOTT's noble fancy or in the humour and pathos of DICKENS. Poetry and romance have an undoubted applicability to the needs of the profession of medicine. Medical life is contracting or broadening, material or spiritual, according to our habits of thought and individual susceptibility, just as the same course of discipline now evolves a hero, now a craven. There are some to whom man in his birth and death, his laws of health and of disease, his passions and his capacities, seems but little elevated above the beasts that perish. Others, again, see an infinite pathos and an unfailing purpose in the great drama of human life, and amid the vicissitudes of hardship, suffering, and disease recognise the essential nobility of man. Poetry and romance are one mode of deciphering the perplexing enigmas of existence, and those whose daily path is through the valley of the shadow of death will do well sometimes to avail themselves of their luminous aid. Medical practice being essentially a process of observation of human life and human fortune, the practitioner will derive peculiar satisfaction from the writings of the philosophical essayists, such as BACON, MONTAIGNE, or EMERSON, in whose works he will find the facts which daily meet his eye analysed from a point of view widely different from his own. He regards human life in the concrete, they in the abstract. He deals with men and women, they with *man*.

Works of travel may be recommended for recreative reading, not merely from their intrinsic interest, but because of the important part which climatic treatment is beginning to play in the therapeutics of disease. There never was a time when a knowledge of foreign countries and foreign climates was so practically important to the medical practitioner as to-day; and while it is indisputable that such knowledge can be thoroughly and satisfactorily obtained only from personal experience, it is nevertheless true that much useful information on the subject can be agreeably gained from the vast and increasing literature of travel. It is a sign of the objective and utilitarian spirit of this age that the authors of the best works of travel no longer fill their pages with idle reflections and petty personal details, but furnish us with much precise data for induction in the form of maps, meteorological tables, and statistics of disease.

Recreative reading is a vast subject, and we can but touch its fringe. We desire merely to remind the practitioner that, in availing himself of the stores of literary wealth at his command, there are principles of choice peculiarly applicable to himself, and that the recognition of those principles will tend to the augmentation alike of pleasure and of profit.

THE discussion on Supra-pubic Lithotomy which was held at the Medical and Chirurgical Society at its last meeting is of historical as well as practical interest, for it marks in a very decided manner the revival of an old and discarded operation. Surgeons were met together not to discuss some new procedure, but the advisability of practising an operation which, once in vogue, had been deliberately and repeatedly abandoned on account of its high mortality. It would be a mistake to regard this as a mere swing of the pendulum, for in two important particulars the conditions are different now from those which prevailed when the "high" operation was abandoned in favour of the "low." The most important alteration is that which results from the introduction and improvement of lithotrity. Except in certain special conditions, only calculi of very large size are now removed by lithotomy, and therefore the question at issue has come to be, in the main, Which is the best method of removing *large* stones from the bladder? Looked at from an anatomical point of view this question admits of but one answer, for not only is the anterior part of the pelvic outlet narrow and flanked by rigid walls, but the removal of a large stone through it must be attended with damage to the prostate and may injure other important structures as well. The space above is amply sufficient for all requirements, and, if we exclude the peritoneum, there is no structure or organ about the fundus of the bladder liable to suffer under the manipulation of the "high" operation. The danger of the "low" operation largely depends upon the size of the stone removed, and the mortality rises with each additional drachm of weight. It would have been impossible to remove through the perineum the huge mass of calculous material shown by Mr. RIVINGTON, and success could not be hoped for in stones of much less size. But the danger of injury to the peritoneum in the "high" operation proved so great as to lead to the practical abandonment of this procedure, and it was only when Dr. GARSON showed that this danger could be obviated that surgeons again turned their thoughts to this operation. It is the combination of these two conditions—the reserving for lithotomy of cases of very large calculi only, and the demonstration of the means of avoiding injury to the peritoneum—which has tended more than anything else to revive the supra-pubic operation. On this point professional opinion is fairly unanimous; but the discussion last week showed a marked divergence of opinion on two questions of considerable importance—the value of rectal distension and the relative advantages of the "high" and the "low" operation for small stones. Dr. GARSON's experiments are well known; they have been endorsed by PETERSEN, THOMPSON, and BRYANT; but Mr. BARWELL controverts them, and urges that any safe amount of distension of the bowel is powerless to raise the reflection of the peritoneum from the bladder to an appreciable extent. In such a matter positive evidence is of more value than negative; and we cannot but think that Dr. GARSON has proved his point, and that the bulk of recent clinical experience affords very strong support to his view. Such a fact as that mentioned by Mr. CADGE, as well as others, shows, however, that care must be exercised in this matter, or serious mischief from stretching, compression, or rupture of the bowel may result. Not only does the plan of rectal distension push upwards and forwards the bladder and expose a considerable surface above the pubes, but it supports the viscus below and renders the manipulation of its interior more easy. This point was insisted upon by Sir HENRY THOMPSON, and is certainly one of some moment. The distension of the rectum carried out cautiously is likely, therefore, to be generally resorted to, although it has been shown to be not free from danger.

Digitized by Google

The discussion as to the choice of an operation for children, or when from any circumstance a *small* stone in the adult has to be removed, is by no means closed. Much can be urged on both sides. For such cases the perineal operation is simple and safe, whereas our modern experience of the "high" operation is but slight, and mainly gained under the condition of a very large stone to be removed. But looking to the danger and inconvenience resulting from any injury to the neck of the bladder, and the proved safety of the supra-pubic operation, it is probable that it offers us the best means of removing even small calculi. This is particularly the case in children in whom the bladder is an abdominal rather than a pelvic organ.

To sum up, then, the position would seem to be fairly stated as follows. For the removal of very large stones, such as are now generally reserved by lithotomy in adults, the supra-pubic operation is distinctly superior to the perineal, being both safer and offering greater facilities for the extraction of very large stones. For small stones which are not removed by lithotrity the line of practice is less clearly defined; but the "high" operation should be thoroughly tested, as it appears to possess distinct advantages over the "low." Distension of the rectum is useful both in supporting and raising the bladder and in separating the peritoneum from the pubes, but care must be taken not to injure the bowel by too great distension.

DISCUSSIONS on medical education and legislation have more than once exhibited our brethren north of the Tweed in a very susceptible mood. If they have not exactly resented criticism, they certainly have not courted it; and anyone who has ventured to call in question the economical and scientific organisation of the Medical Faculty in Edinburgh has not had an easy time of it. But Scotch criticism of Edinburgh doings must be free from the suspicion of jealous inspiration, and its accuracy cannot be at fault for lack of local information. To such a criticism on professorial work and professorial pay in Edinburgh, the *Scotsman* of Friday, the 2nd inst., devoted no less than three columns and a half. Their perusal gives a rude shock to the prevalent notions that science does not pay, and that scientific men are not good men of business. The times are admittedly hard, but if the Scotch professors have ever heard of shrinkage of income, they certainly have not realised it, if we are to judge from the *Scotsman's* figures. The clear income of the fortunate incumbent of the Anatomy chair, is in round numbers £3400, and his physiological colleague nets about £2100. The summary is very remarkable:—Total income of chairs in medical faculty, £26,628; total expenditure of chairs in medical faculty, £5180; total clear income of chairs in medical faculty, £21,230. Average clear income—(1) Of five professors without practice £2200; (2) of seven professors with practice, £1460. "Universities exist, not for the professors, but for the public; and in the public interest it is desirable that the University revenues should be employed in the way most advantageous to the students and to the community. Surely a gross income of £26,600 ought to maintain more than twelve professors, no matter how eminent. If that sum were paid into a common University chest, as has been proposed, there is no doubt that wise and careful administrators could equip with it a medical faculty, not of twelve, but of twenty chairs at least, with the necessary complement of assistants to each. There would also be in that case an increase in the amount of research work done in the University, which is at present shamefully small. The shortcoming is due partly to the lack of research endowments, partly to the fact that the professors are too well off, and have a tendency—with a few notable exceptions—to rest with their laurels, and to become indifferent to the progress of science." These are not the expressions of an English critic, but the *ipsissima verba* of the *Scotsman*.

Annotations.

"Ne quid nimis."

THE ELECTION OF PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS.

IN answer to many inquiries respecting the forthcoming election to the presidency of the Royal College of Physicians, we may repeat the statement we made last week, that we have no doubt that Sir William Jenner, if elected, would consent to serve for another year. There can be no question that at present, when important matters affecting the vital interests of the profession are pressing for solution, the occupancy of the presidential chair by Sir William Jenner for another year would be of the greatest advantage, not only to the College of Physicians itself but to the whole profession.

"REST AND REPAIR IN LONDON LIFE."

DR. ROBSON ROOSE has followed up his article on "The Wear and Tear of London Life," which appeared in the *Fortnightly* of February, with a paper on "Rest and Repair in London Life" in the number for April. The supplement is a pleasantly gossiping discourse on the best method of self-management in view of the worry and waste which life in society entails. There is much to interest the reader, and likely to prove useful, in the advice offered. On one point which may be specially noted Dr. Roose's counsel is of great importance. Treating of the difficulties of digestion which so commonly embarrass brain-workers, he directs attention to the great need there is of recognising the absolute requirement of power to digest when food is taken. Thus: "Take the case of a man who, after a hard day's work, sits down to dinner at eight or half-past, having taken a hasty and scanty lunch some hours previously. His sensations tell him that he is terribly in want of food, but they do not warn him that he has little or no power of digestion left. He eats freely and rapidly, and one form of discomfort is soon exchanged for another. Digestion goes on very slowly and the process is far from complete when bedtime comes. The sufferer is weary, but sleep is unrefreshing, and probably broken by dreams or nightmare. He begins the succeeding day weighted with the burdens of its predecessor." This is a true picture. The "power of digestion" is a necessity, and it is quite possible to be too much exhausted to take advantage of nutriment which has been too long withheld. The energy of recuperation may be itself impaired by whatever unduly exhausts the organism, and when this is at a low ebb there will be difficulty in the process of recovery by digestion and assimilation. Dr. Roose thinks seven o'clock is quite late enough for the dinner hour, and he would make the luncheon a fixed meal. He also recommends half an hour's rest before dinner. This he believes would "avert many of the troubles which are caused by taking food when the stock of nervous energy necessary for digestion has been well-nigh exhausted."

Digitized by Google

We allude to this point only, but Dr. Roose discusses with much ability and in a practical sense most of the matters of moment relating to the subject he has taken in hand.

HOSPITAL ISOLATION OF SCARLET FEVER IN LONDON.

IN the Registrar-General's Annual Summary of the vital statistics of London and other large English towns in 1885, which has just been issued, attention is called to the fact that the mortality from scarlet fever in London has during the last fifteen years been constantly below the mean mortality in the whole country, while the London mortality from both measles and whooping-cough has shown an excess almost as constant. Moreover, it is pointed out that prior to 1871 London did not enjoy such comparative immunity from epidemic scarlet fever, the mortality from this disease being higher than the mean rate in the whole country. It is suggested that this recent marked decline in the mortality from scarlet fever in London may be to some extent due to the increasing use of public hospitals for the isolation of cases of this disease. In support of this suggestion it is stated that 5 per cent. of all the deaths from scarlet fever in London in 1878 were recorded in the fever hospitals under the control of the Metropolitan Asylums Board. In the next three years, 1879-81, the proportion ranged between 7 and 8 per cent., in 1882 the percentage rose to 9·3, in 1883 to 11·4, in 1884 to 16·4, and during last year 19·2 per cent. of the deaths from scarlet fever occurred in these hospitals. This suggestion as to the cause of the persistently low death-rate from scarlet fever in London in recent years deserves, as the Registrar-General remarks, the serious attention of those engaged in the sanitary administration of our large towns.

ILL-DEFINED FEVER.

ATTENTION was recently called to the fact that during the ten years 1871–80 there were 25,643 deaths registered in England and Wales from "simple continued fever," and that under this heading are doubtlessly classed more than one disease. It may be useful to refer to this subject in order, if possible, to throw some light upon the true signification of this heading. Prior to 1869 the certification of deaths from "fever" was so unsatisfactory that no attempt was made in the Registrar-General's reports to separate even typhus from enteric or typhoid fever. The report for 1869 gives 4231 deaths from typhus, 8659 from enteric fever, and 5310 under the heading then called "simple continued fever," which included all deaths from "fever" which could not be placed under the other two headings. The "fever" heading in the Registrar-General's reports prior to 1869 was somewhat unfortunately called "typhus," and there is no reason to doubt that the word "typhus" continued long after that date to be loosely used in medical certificates as a generic term for "fever." Medical certificates have, however, much improved in this as in other respects in recent years, and on reference to the last published annual report we find that only 963 deaths were referred to the heading now called "simple and ill-defined fever," to which, as in 1869, when the distinction was first introduced, all deaths from "fever" are referred which cannot be classed either as typhus or enteric fever. Thus, in 1869, 29 per cent. of all the deaths from "fever" were referred to "simple and ill-defined fever" for want of definite description in the medical certificates; whereas in 1883 the proportion of these ill-defined "fever" deaths had fallen to 12 per cent. It is not without interest to inquire how these fatal cases of ill-defined fever are described, and the Registrar-General's weekly returns throw some light upon this question, as cases of ill-defined fever in London are there referred to in detail. The number of these ill-defined fever deaths in London in 1885 were 82, against numbers declining steadily from 312 in 1875 to 78 in 1884. Of these 82 deaths, 25 were merely described as "continued fever," giving no assurance that some of them were not really cases of scarlet fever or even of small-pox; only 13 were described as "simple continued fever"; 13 merely as "fever"; 7 as "febricula"; 9 as "low fever"; 2 as "eruptive fever"; 2 as "simple fever"; and 2 as "suppressed fever." The remaining 9 cases were described in as many different ways, such as infantile fever, exhaustive fever, acute specific febrile disorder, &c. There is no reason to doubt that the gradual decline in the proportion of these ill-defined cases of "fever" will continue, but in the meantime due account must be taken of this disturbing element when comparing the death-rate from enteric fever in recent years, as the registered numbers of deaths from this disease are being constantly increased by the transference of deaths from ill-defined forms of fever; while, on the other hand, the number of deaths incorrectly referred to typhus is as constantly decreasing.

FOOD PRESERVATIVES.

AN interesting paper was recently read by Messrs. Sulman and Berry before the Chemical and Physical Society of University College; it was important also from its practical bearings on the preservation of foods, and especially milk. Their investigation, limited to the boracic, salicylic, and benzoic compounds, proved that such substances as aseptin, glacialine, and boroglyceride owed their preservative qualities almost exclusively to the free acid contained in them. Boroglyceride contained 25 per cent. of the genuine boracic ether of glycerine, and 75 per cent. of free acid and glycerine in equivalent proportions. The true compound, the ice-like solid, is immediately resolved into free acid and glycerine by the addition of water, and this reaction probably takes place when the true compound comes into contact with aqueous liquid or animal tissue. We agree with the authors of the paper that the use of so much free boracic acid is undesirable and injurious, especially as a preservative of milk for children. Salicylic acid and salicylates are not substances that can be used with impunity, and as they appear to be useless as preservative agents, their rejection is doubly necessary. Again benzoic acid precipitates the casein of milk. The best agent appears to be benzoate of soda, which is tasteless when pure, is one-third more powerful than boracic acid, and innocuous when taken in small quantities for prolonged periods.

LATE CLOSING IN WHOLESALE HOUSES.

WHOLESALE traders have all along been the most steady opponents of the measure for reducing the working hours of shopmen. They endeavour to defend their position by a double argument. On the one hand, they seek to convince us that an occasional sudden influx of custom demands, while it lasts, a prolongation of the period of daily work in order to meet it, and that this cannot be obviated; on the other they would have us believe that, slack and busy seasons taken together, the average duration of work bears very lightly on the employed. With the former contention we do not now concern ourselves, though it must be obvious that more men working within an allotted time will do as much as fewer working overtime. With regard to the question of average daily occupation, there is apparently much variation in the evidence of statistics. Some of our readers have doubtless been struck with the announcement of Mr. Alderman Evans that seven and a half hours represented the mean working day in most of the large warehouses in the City of London throughout the year. The statement is

Digitized by Google

a remarkable one. It may, as Mr. Evans maintains, find some confirmation in the usage of the firm with which he is connected. We cannot accept it as generally applicable. It is exceedingly difficult of reconciliation with the notoriously long working time in many similar establishments in seasons of pressing business, except on the supposition that for a great part of each year trade of a given kind can hardly be said to exist. Callings which admit of so much leisure are fortunately few. Their influence cannot seriously affect the general course of corrective legislation. Facts have, on the other hand, been adduced by a writer in opposition to the above statement, which show that in certain large wholesale establishments young boys are worked for five or six months a year from 7 or 8 A.M. till 10 P.M., and even till after midnight, during five days in the week. Are we to understand that in houses of this kind no work at all, or next to none, is carried on during the rest of the year? On no other theory can these conflicting facts be made to agree, and ordinary commercial practice forbids this supposition. Should we even go so far as to admit that a low average may thus be attained, the proof in favour of late closing is still imperfect. It by no means follows that the stamina of youths, however robust, should be put to so severe a test as a strain of labour continued for several months, and occupying every hour during which recreation is ordinarily possible, save perhaps those devoted to meals.

MYCOTIC ENDOCARDITIS.

DR. WYSSKOWITSCH details the particulars of an experimental inquiry into the nature of ulcerative endocarditis (Virchow's *Archiv*, 103, Heft 2), to which is prefixed an account of the histological examination of twelve cases of endocarditis in the human subject. Four of these cases were chronic valvular thickening with calcification and necrotic areas, surmounted by warty deposits of fibrin; in four others the vegetations were more or less vascularised at their union with proliferated endothelial layers (thrombo-endocarditis); the ninth case appeared to be a chronic condition of the preceding; the tenth and eleventh showed post-mortem œdema after chronic endocarditis, with, in one case, bacteria (undoubtedly saprophytes). Lastly, there was a recent case of ulcerative endocarditis, which yielded abundance of micrococci on the valves, in the spleen and kidneys; on cultivation the micro-organisms had the characters of staphylococcus pyogenes aureus. The experiments which form the second part of his paper consisted in inflicting on rabbits an injury of the aortic valve by means of an instrument passed down the carotid artery; then injecting into a vein a few hours later cultures of various micro-organisms. It was shown that the operation of piercing the valve was well borne, and not *per se* followed by any pathological consequences; but that the inoculation was often productive of a malignant mycotic endocarditis upon the injured valve, with secondary metastasis, as in human ulcerative endocarditis. These positive results occurred when the inoculation was made with either of the following micro-organisms: Streptococcus pyogenes, staphylococcus pyogenes aureus, and coccus sepsis (Nicolaier); but the injection of micrococcus tetragonus and bacillus pneumoniæ had no such sequel. It was also found that the staphylococcus produced much inflammatory reaction and suppuration, whereas the streptococcus, although causing much more valvular deposit and more numerous infarctions, had no such severe action. The changes in the heart and vessels were not limited to the valves pierced by the stylet; the micrococci growing also on the mitral valve and aortic wall, which happened to be eroded by the passage of the instrument. It is therefore suggested that mycotic endocarditis may be of various forms depending upon different varieties of micro-organism. Other experiments to induce endocarditis after inhalation and subcutaneous injection of streptococci yielded negative results; but it was found that the rabbit can only bear inhalation of very small quantities, and it was doubtful if the micro-organism entered the blood stream at all. Professor Orth, under whose direction this research was undertaken at Gottingen, comments in another article upon the results obtained; they prove, he thinks, that the term "disposition" is no empty one, the mechanical injury of the tissue laying it open to the attacks of the micrococcus which is deposited in the clots. The experiments show also how slight may be the amount of injury required to so lower the vital resistance of the tissue.

VACCINATION AND THE HOUSE OF COMMONS.

EXTRACTS from the 1884 Report by Dr. Buchanan, F.R.S., to the Local Government Board on the subject of the Relation of Small-pox to Vaccination are being distributed by that Board to members of Parliament and others. The convincing proofs which those extracts afford of the immense benefits conferred by primary vaccination on the infantile population, and by efficient revaccination on those of a more mature age, will, we trust, come with new force at a time when the list of notices of motions in the House of Commons contain indications of attempts, more or less direct, to deprive that class of our population which is alone unable to take care of itself of the greatest protective against preventable disease which has ever been discovered. It would be well for all who have the welfare of their fellow-men at heart to urge members of the House of Commons carefully to study these extracts before recording any vote on the vaccination question.

THE LEA AND RIVER POLLUTION.

THE Parliamentary Committee appointed to inquire into the state of the River Lea sat again last week, and received the evidence of Major Flowers, the engineer of the Lea Conservancy Board, who gave an account of the steps taken to abate nuisance. Major Flowers is reported to have stated in the course of his evidence that he was of opinion that "no chemical process was of itself sufficient to bring sewage water up to a point of purity at which it might safely be restored to a state that would allow of drinking-water to be drawn from it, or the state in which the river should be for the purposes of recreation." The Luton sewage, he said, had proved a difficulty, and at his suggestion had been dealt with by means of a sewage farm, but the effluent was impure, as it could not be freed from all the chemicals which were mixed with it. Major Flowers' evidence as to the general condition of the Lea in its several parts will be read with interest at a time like the present, when there is indication of the reappearance of cholera in France. Above the first intake of the New River Company the water was good—as far as river water could be good. Between Hertford and Ware, where the Manifold Ditch fell into one of the affluents of the river, the appearance of the ditch-water was black and slimy; the black slime could be seen lying on both banks of the river, and a nasty smell was present. At Cheshunt, above the East London Water Company's intake, there was a great deal of pollution from sewage being pumped into the river. Sir Frank Bolton stated that he had analysed the water at the East London Water Company's works, and found but few traces of pollution; this he attributed to the great volume of water; but the East London intake compared unfavourably with that of the New River Company. Concerning the general question of river pollution, we are informed that the Rivers Pollution Bill did not meet in the House of Commons with

Digitized by Google

the consideration that was expected, very much because Mr. Hastings, who had charge of the Bill, was unavoidably absent on the night it came up for the second reading. The statements of the Attorney-General at the Mansion House meeting on the 10th ult. had led the Society which was promoting the Bill to assume that it had the approval of the Government, and they were therefore much taken by surprise at the course the Government subsequently adopted. It was certainly unfortunate, under these circumstances, that Mr. Hastings, who could have explained all its details, was not present.

FORMATION OF MARSH GAS AND CARBONIC ACID FROM CELLULOSE.

HOPPE-SEYLER has come to the conclusion that the production of marsh gas is the result of a process of fermentation of a very general character. He has examined a large number of gaseous discharges taken from places where the water was pure but the soil contained several kinds of vegetable matter. It was found that marsh gas preponderated under such circumstances, more than half the volume of gas collected being composed of it; the remainder consisting of nitrogen, hydrogen, and sometimes oxygen and carbonic acid. Warm weather increases the emanation of gas from waterlogged soils. Observations on Lake Constance showed that temperature has far more influence than the composition of soil in the production of gas. The next step in the process of discovery is the source of the gas—the kind of organic matter. There seems to be but little doubt that the cellulose of vegetables is the material source of the gases; vegetable remains anywhere deposited become humus substances. If a glass flask, with drawn-out neck dipping under mercury, be filled with mud containing vegetable remains and water, a mixture of gases may be obtained consisting of marsh gas, a large proportion of carbonic acid, and a little nitrogen, that soon disappears. This development of gas may go on for months, the quantity evolved varying with variations of temperature, though the total discharge differs but little. In nature the carbonic acid diffuses rapidly into the surrounding water, by which it may be dissolved, or where the water is shallow, elaborated by plants, so that the tension of carbonic acid on the surface of mud is always kept low. In spring, with its low temperature, the soil becomes coated with diatoms, decomposing the carbonic acid and favouring diffusion by their movements. Low forms of plants displace the diatoms in the summer time. The influences of this general process of gaseous evolution upon the life of organisms and on geological strata and lodes must be great indeed, and Hoppe-Seyler promises further information from future investigations.

THE TAUNTON SANITARY HOSPITAL.

THE so-called Taunton Sanitary Hospital affords an example of the great utility of establishments provided by sanitary authorities for the isolation of cases of infectious diseases. It was the result of joint action between the urban and rural districts of Taunton, and was ready for use in 1879; accommodation being provided for the immediate and simultaneous isolation of first attacks of at least two different infectious fevers in both sexes by means of twenty-four beds, each having 144 feet of floor space and 2000 cubic feet of air, together with ample means of ventilation. Each year Dr. Alford issues a special report of the proceedings of this institution, and he has been able to show, over and over again, how wise has been the expenditure which was originally incurred in erecting the buildings, as also that still devoted to the maintenance of the hospital. During 1885 no less than 205 cases were admitted, 166 coming from the urban and 39 from the rural district. The number of patients was exceptionally large; it was brought about by an importation of small-pox, and it necessitated the provision of temporary buildings. Many authorities have objected that compulsion would be necessary to the proper use of such a hospital. This has been conclusively shown to be an erroneous view in the Official Report on the Use of Infectious Hospitals; and Dr. Alford's testimony is in the same direction, for he states that he has not had occasion in any case to resort to compulsory powers in order to secure removal to the hospital. He admits what is well known—namely, that it is amongst the most ignorant and the poorest that the greatest objection is found to accept the means of isolation afforded by such a hospital. There is, however, no more powerful method of removing the ignorance which leads to this feeling than the provision of a hospital, every separate use of which has its educational effect on the classes benefited by it. In Taunton some people use the building who desire to pay for the privilege, and £54 were thus reimbursed to the authority; but this is only an incidental feature in the finances of the district, the main point being that a vast sum in excess of the cost of isolating 205 cases of infectious disease was saved, which would have been incurred if these cases had been left to distribute infection in all directions.

THE ISOLATION OF DIPHTHERIA IN THE METROPOLIS.

WE are informed that the managers of the Asylums Board, having been requested to receive cases of diphtheria into their hospitals, and being precluded from doing so by the orders under which their institutions are regulated, have communicated with the Local Government Board on the subject. Every year makes it more and more evident that the Metropolitan Asylums Board must become the principal Isolation Authority for London, and it must be clear to all who know how largely prevalences of diphtheria are due to the spread of infection from person to person, that no such authority can fully perform the duties required of it which does not arrange for the isolation of cases of that disease. The large amount of accommodation hitherto held in readiness in London for the reception of cases of small-pox could easily be devoted to other infectious diseases, including diphtheria, now that small-pox is, with certain exceptions only, to be at once removed to floating and land establishments down the river.

MEDICAL ORDINANCE, CANADA.

THE following regulations relating to medical practice in the North-West Territories, Canada, were passed at the close of last year by the North-West Council. The Ordinance No. 11, relating to medical practitioners, provides that any person not registered according to the ordinance who practises or professes to practise physic, surgery, or midwifery in the North-West Territories for hire, gain, or hope of reward, or who advertises to give advice on these subjects, shall upon summary conviction before a justice of the peace be liable to a fine not exceeding $100; and any such person who takes or uses any name, title, addition, or description implying or calculated to lead people to infer that he is recognised by law as a physician, surgeon, accoucheur, or licentiate in medicine, surgery, or midwifery shall also be liable to a similar fine, the burden of proof in such cases to be upon the person charged. These penalties are recoverable from March 1st. The following persons are allowed to register under the ordinance:—(*a*) Persons residing and practising medicine &c. in the territories on December 18th last who hold a medical degree, diploma, or licence from any university, college, or corporate body in Her Majesty's

Digitized by Google

dominions empowered by law to grant such degrees or licence, on payment of a fee of $5. (*b*) British subjects resident in the territories who have been practising medicine therein for one year previous to December 18th, 1885, who hold a medical degree, diploma, or licence from any university or college in the United States whose curriculum demands two years' attendance at medical and surgical lectures, which is authorised by law to grant such degree or diploma, on payment of a fee of $5. (*c*) Persons residing and practising medicine in the territories for one year previous to December 18th last, who shall before December 18th, 1886, pass an examination before any two medical practitioners, registered under the ordinance, appointed by the Lieutenant-Governor, on the subjects of anatomy, chemistry, physiology and materia medica, the principles and practice of medicine, surgery, and midwifery, paying such examiners a fee of $10 each, receiving from them a certificate, and paying a registration fee of $25. (*d*) Persons who shall hereafter become residents of the North-West Territories possessing the qualifications set forth in sub-section *a*, on payment of a registration fee of $50. Fees payable under the ordinance go to the general revenue fund of the territories.

HOSPITALS AND THEIR CLAIMS.

WE are glad to see the Duke of Westminster and others, who have it in their power to give great help to hospitals, expressing themselves publicly in support of these institutions, which are places of hospitality and help to all—even to the rich when overtaken with accident, but mainly to the poor. The public little know what generous service is given gratuitously and secretly to the poor by the members of our profession, or they would be eager to share the service by such gifts as they can bestow. We quite casually heard the other day of a senior physician of a northern metropolitan hospital being consulted in the middle of the night by a careful house-physician about two urgent cases of poor children who had been brought in. With true humanity, the physician lef this bed and home and went to see the cases for himself. It is facts of this sort that we commend to the consideration of those who—not from want of heart, but from want of thought—leave the problem of hospital support to hospital physicians and committees, as if some secret manna and comfortable beds fell down from heaven into these institutions, where the poor have the advice and skill they cannot buy.

THE PEND-JEH SORE.

DR. SUSKI, while on duty with his regiment in the neighbourhood of Merv, describes in the *Vrach* (No. 9, 1886) what is known in that locality as the Pend-jeh sore, which, he says, attacks nearly all persons who live or stay in the neighbourhood of Pend-jeh. His description is unfortunately limited to the naked-eye appearances, as he was unprovided with microscopical apparatus. He divides the disease into three stages. 1. A red spot appears, about the size of a millet-seed, which gradually increases to that of a pea or larger, in the centre of which a hard papule develops, which suppurates, bursts, and forms a primary sore, affecting the whole thickness of the skin, of a circular shape, about the size of a hemp-seed, with a dirty base and precipitous edges. 2. The sore enlarges, and close to it a second develops in the same way as the first, which, in its turn, is succeeded by others; these run together in groups, forming compound sores of the size of a five-kopeck-piece—i.e., of a penny—or even larger still. These affect the whole thickness of the skin, and have vertical edges and swollen circumferences, and are of a red colour. In addition to the sores, small enlargements appear in the thickness of the skin of the limbs, having the general direction of the lymphatics. The colour of the surface over these nodes undergoes no change. They are looked upon by the natives as pathognomonic of the disease. The larger glands were not swollen in any of the cases under observation. The sores secreted a considerable quantity of pus. 3. The healing process commences after the sores have been open for some time, and it nearly always begins at the spot which was first attacked. Granulations arise having a papilliform appearance, and reach the level of the skin or sometimes rise above it. These cicatrise usually under scabs, and if the latter are carefully removed the cicatrices themselves are seen to have a papilliform appearance. Between the healing points small dark-grey scabs appear, consisting of dust and dried pus, as may be seen with the aid of a lens if they are treated with alcohol and water. These little scabs are so closely adherent to the papillæ of the healing sore, that even when very carefully removed with forceps the apices of the papillæ are torn off and hæmorrhage occurs to such an extent sometimes as to require to be arrested. As the cicatrices harden the papillæ become atrophied. The cicatrix is depressed, and in the course of time becomes of a whitish appearance. The author believes that all the sores are developed from hair follicles, their favourite seats being the wrists, the ankles, the waist, the abdomen at the level of the waist, the forehead, the neck, and the face; more rarely the supraclavicular regions, the legs, the hands, the thorax, the back and the shoulders. With regard to the causes of the disease, he thinks they are to be found in the all-pervading powdery sand, the heat, which throws a great deal of work on the cutaneous glands, the bites of insects, and the sudden variations between day and night. The treatment found by Dr. Suski to be most advantageous was to wash the sores with a solution of corrosive sublimate of the strength of 1 to 1000, and dressing them with a mercurial ointment. At a subsequent stage a mixture of iodoform and alum was employed, and finally cauterisation with nitrate of silver.

THE HOMES OF THE WINDSOR POOR.

THE steps which are being taken to improve the sanitary condition of those parts of Windsor which were described last year at much length in our columns are necessarily slow, but we have reason to believe the difficulties are not insurmountable. Two distinct lines of action are required: the first involves the demolition of the unhealthy houses and the clearing of the site; the second, the reconstruction of proper homes for the working classes. To attempt to erect these on the site of those which are demolished would probably involve a larger expenditure than would make a reasonable pecuniary return; but money invested in this manner gives to a town an improved healthiness, diminishes sickness amongst those who at such times become a charge upon the ratepayers, and therefore it is unfair to look for more than a small rate of pecuniary interest on the money invested. There is, however, no reason why the scheme for improving Windsor should necessitate the erection of houses in the immediate locality of Bier-lane; Windsor is not so large that it would inflict a hardship on the residents of that part of the town if they were expected to occupy houses a short distance away, and where land for building could be had at a much lower cost than the site which is cleared. We understand that the Corporation would not be unwilling to entertain a scheme for laying out a road which would pass right through the unhealthy area, and which would lead to the demolition of some of the worst buildings; but if the Corporation were to adopt this course, there is no reason why the duty of building suitable houses for the inhabitants who are displaced should not be undertaken as a matter of private enterprise by those who wish Windsor well. We do not think there would be any lack of funds for this purpose

Digitized by Google

if the Queen were to give expression of approval to this plan. We are convinced that any measure which promises benefit to Her Majesty's poorest subjects will have the Queen's sympathy, and nothing but her great influence is required to set in motion those who would gladly devote their efforts to carrying out her wishes.

ALLEGED DEATH FROM HYDROPHOBIA.

AN inquest was held on April 3rd by Mr. Braxton Hicks, at the Parish Offices, Putney, touching the death of Hannah Phillips, aged fifty-five. The deceased seemed in good health until March 27th, but then complained of faintness and a choking sensation. On the following day she seemed to have "hysterics," which came on "whenever a drinking vessel was shown to her." Death occurred on March 30th, after paralysis had set in. At the post-mortem examination the pharynx and spinal cord were found much congested, the blood fluid, and inside the lower lip were some abrasions, which, on the evidence of Dr. Walker, were of "uncertain age." Now the deceased had a pet dog with one tooth, and it was suggested to her that she might have been bitten by the dog, but this she denied. In consequence of this suggestion, probably, she seems to have taken a dislike to her old companion and bedfellow, the said dog. Dr. Walker was of opinion that the cause of death was hydrophobia, but as there was some doubt on this head the inquest was adjourned in order to enable the police, under whose care the dog had been placed, to report on the state of its health. We must confess we are sceptical on the matter. Some of the symptoms of the deceased read uncommonly like those of angina pectoris—a condition, by the way, rare in the female sex. To our minds the post-mortem signs are too equivocal to form a reliable basis for a conclusion as to the real cause of death. We shall look forward with curiosity and interest to the fate reserved for the dog, whose reputation may be considered to be "under a cloud."

THE BEAUFORT LIMB ABROAD.

"THERE will come a time," says General H. H. Maxwell n his Seventh Report on Arms and Legs in Rome, "when the peg-leg will be as dead as the dodo," and the rapidity with which the Beaufort limb is finding favour in Europe more than justifies the prediction. The last *Bulletin Trimestriel*, the organ of the Count's own charity, "L'Assistance aux Mutilés pauvres," teems with evidence of the good effected by the rehabilitating invention—of bread-winners saved to themselves and their families, of the dread of amputation minimised, and of the army of labour reinforced. Science is thus made to walk hand in hand with benevolence, and the almsgiving public, in subscribing to the charity, have the comforting assurance that here at least their bounty is not wasted. From France the limb has won its way to Holland, where General de Stuers, ably seconded by Count de Limbourg Stirum, has founded a society for providing it to all deserving applicants. Of all Count Beaufort's lieutenants, however, the earliest in the field and the most successful in action has been General Maxwell, whose annual reports of the charity in Italy are looked forward to, not only for their record of substantial service done, but for the dramatic interest of their details and their pleasant vein of style. The report just issued—the seventh—is, except perhaps the first, the most interesting he has put forth, as showing, *inter alia*, how effectively he has overcome the crucial difficulty of securing perfect coincidence between the joint of the artificial and the joint of the natural leg. He can thus from Rome, with absolute certainty that there will be no misfit, supply M. Werber in Paris with measurements which enable that accomplished mechanician to furnish the required limb in a few weeks, and to send the quondam cripple on his way rejoicing. The General's mathematical proficiency has here stood him in excellent stead, with results that, gratifying as they eminently are, must be more than needed to sustain him in face of the *mitrailleuse* of mendicancy with which the charitable Englishman is in Latin countries assailed. A narrative of the consequences he has incurred by his "craze for cripples," and of the experience he is daily acquiring in turning the flank of the begging-letter writer, concludes in a vein of humorous melancholy his seventh year's record of assistance in setting lame Italy on its legs.

ST. MARY'S HOSPITAL.

ON April 3rd the annual festival dinner in aid of the funds of St. Mary's Hospital was held at the Albion Tavern, the Right Hon. the Lord Mayor presiding. From the report of the Secretary it appeared that the working of the past financial year had left a deficit of £6380, which was accounted for partly by increased expenditure incurred by the opening of new wards, and partly by a falling off in legacies. From want of funds the authorities of the hospital were unable to open the large accident ward of the new Mary Stanford wing. Owing, however, to the public spirit and munificence of Mr. J. D. Allcroft, the governors had been enabled temporarily to overcome the latter difficulty. This gentleman has endowed the new wing for two years, at a cost of £2000 per annum. We sincerely trust that the step taken by Mr. Allcroft will be followed in regard to other charities by the possessors of wealth in the metropolis. There is no reason why any one of our general hospitals should be crippled in its usefulness for want of supplies. We maintain that money spent on our public medical institutions is well laid out, for it gives to the suffering poor such aid in their affliction and infirmities as can be obtained in no other way. More than this, it decreases the rates by checking the influx upon workhouses and workhouse infirmaries. Dean Swift, when preaching on behalf of a charity, found, to his chagrin, that the morning's collection fell short of the anticipated and desired total. On being informed that it would be advisable to curtail the evening's discourse, since the one in the morning was long enough to weary his hearers and tighten their purse-strings, the celebrated divine decided to act on the advice. He took for his text the words, "He that giveth to the poor lendeth to the Lord," and with characteristic piquancy added, "Now, my friends, you know the terms—if you like the security, down with the dust." We heartily recommend to our readers the study of Dean Swift's racy address. Slightly altering a saying of Mr. C. H. Spurgeon, embodying a proposition and an appeal, we would venture to remark to the affluent, "The poor are your children; you will not let them starve."

THE PREPARATION OF WHEAT FLOUR.

ANY reform which aims at improving the quality of bread must be of general and professional interest. Late years have seen considerable changes in this direction. They have witnessed the reduction to something like its true place in public esteem of mere colour as a test of nutritive value. People think less of the white loaf than of yore; it is not now the unique model of perfection in bakery that it was once too readily taken to be. There is more respect for its brown wheaten fellow; and while we are not prepared to admit without reserve all the excellencies which have been claimed for the latter, we may fairly allow that it deserves to rank as a food of highly nutritive efficacy. The principle which preserves in the bran, with its nitrogenous, fatty, and saline constituents, some of the best constituents of wheat, is on the whole a

Digitized by Google

sound one. Its one objection is the inseparable association of irritating siliceous matter, which often precludes its free use among the sick, and in any case requires that the grain should be ground with more than usual care. This fact also places somewhat of a restraint upon the consumption of such bread even by the healthy. Among various methods which have been devised in order to meet this difficulty, our readers will recall that of Mége-Mouriès, which, by preserving the inner envelope while removing the outer coverings of the grain, succeeded in retaining most of what was nutritious in the bran with comparatively little indigestible or irritant matter. A revival of this mode of preparation has lately been described by Mrs. K. J. Dance in a little paper on bread-making. The authoress claims for her system that it is both more efficient and more expeditious than other processes now in use. Respecting its proper place among such we need not now express an opinion, but the soundness of the theory on which it is based at all events justifies the claim put forward that it should be fairly tested as to its practical value.

THE GENERAL HOSPITAL, JERSEY.

THE lamented death of Mr. Godfray of Jersey leaves a vacancy in the General Hospital. This hospital is an important institution, being the hospital for all Jersey, which has a population of 60,000. Hitherto all the work has been done by only one officer. It is felt almost universally by members of the profession in the island that this arrangement is indefensible. It is not in the interest of the poor that one man should be responsible for so much medical, surgical, ophthalmic, and other special work as is implied; still less is such an arrangement in the interest of medical science and art. Accordingly a petition has been forwarded to the States, and a letter to the Jersey Hospital Committee, on behalf of nearly all the registered practitioners of the island, praying that hereafter the hospital should be officered, as are all similar institutions in England and on the Continent, by a staff composed of two physicians, two surgeons, one physician for the treatment of women and children, and one for ophthalmic and aural cases. We do not doubt that the States and Hospital Committee will agree to some such arrangement as this. The public as well as the poor have a direct interest in making the work of the hospital as efficient as it can be made. By enlarging the staff the work will be better done, and all the advantages of a higher cultivation of hospital work will accrue to the general population.

WILMER v. AYLWARD AND OTHERS.

NOTHING of interest to members of the medical profession, as such, arises out of this suit, beyond what may attach to the proof that the question of *bona fides*, while all-important, is not in itself sufficient to protect any person acting under the provisions of the Lunacy Acts. It is true that the question left to the jury was whether the medical men had given their certificates "falsely and negligently," and, inasmuch as they did neither, they escaped censure; but the relieving officer, who admittedly acted in good faith, was mulcted in a comparatively heavy sum for damages because he caused the patient to be removed to the workhouse, either negligently or under a wrong impression. No increased sense of security, or perhaps we ought to say diminished sense of insecurity, can result from the decision in this case The fact remains that medical men sign certificates at their peril, and until the law is changed they must continue to do so. Whether the Bill now before the Lords, — if by any strange freak of fortune it should pass the Commons and become law—will place matters in a more satisfactory condition remains to be seen. We heartily hope it may, but meanwhile the counsel so often given in these columns must be repeated. No practitioner should sign a certificate unless he be compelled by the strongest force of circumstances to do so, and in the doing of this act he should bear in mind that he exposes himself to peril of annoyance, if not of injury, and should make his arrangements accordingly.

DRAINAGE OF IDIOPATHIC INTRA-CRANIAL ABSCESSES.

THE evacuation of traumatic abscesses of the brain has long been a recognised procedure, and has met with a fair measure of success. Recently Mr. Hulke has endeavoured to extend this practice to idiopathic abscesses within the cranium. A few months ago a man was admitted into the Middlesex Hospital, under Dr. Cayley, suffering from coma, which had supervened upon a long-standing purulent discharge from the ear. There were no localising symptoms. Mr. Hulke trephined the skull in the lower part of the temporal fossa, and by means of a director explored the temporo-sphenoidal lobe, without result. The operation was unattended with ill-results, but after the patient's death, a few days later, an abscess was found in the cerebellum. Quite recently a woman was under Dr. Cayley's care with similar history and symptoms, and intra-cranial suppuration was diagnosed. Mr. Hulke determined to explore the brain. In this instance he made an aperture in the cerebellar fossa of the occipital bone, and through a small incision in the dura mater he passed a director through the cerebellum in all directions, but without striking an abscess. Finding that the symptoms were unrelieved, he subsequently trephined the temporal fossa, and opened an abscess in the temporo-sphenoidal lobe. We believe these cases will be duly reported to one of the Medical Societies. They mark an important advance in cerebral surgery, but further comments upon them must be deferred until all the facts are before us.

THE BELGIAN MINERS.

AT the first International Congress of Hygiene held in Brussels, under the Presidency of the King of the Belgians, in 1876, the condition of the men, women, and children who work in the coal-mines of the Low Countries was denounced as opposed to the claims of humanity, the laws of health, and the general security of the community; the Belgian Academy of Medicine fifteen years ago pleaded the cause of the mining population; and medical men and sanitary reformers generally have pointed out the irreparable moral and physical injury done by allowing children of both sexes to work promiscuously in coal-mines. In spite, however, of all these earnest protestations, the Legislature of Belgium has done little or nothing to protect those who by hard necessity were compelled to sacrifice every consideration for the sake of a slight addition in the weekly wages earned by miners' families. Up to the year 1884 the work in mines was regulated by an old law dating back to 1813, which only stipulated that no children under ten years should be allowed to work underground. In April, 1884, however, a police regulation, which received Royal approval, was issued forbidding boys under twelve years and girls under fourteen years from working in mines. This of course is an improvement, though still an insufficient protection. The present adult population, however, has worked under the old law, and consequently experienced all its degrading, moral, and physical influences. The men and women are inevitably brutalised by unceasing toil, varied by the hardships of the semi-starvation that denotes periods of depression. The day's work varies from ten to fifteen hours; the wages, never high, have now fallen to at most 2*s.* 6*d.* a day for the fully qualified adult miner; but work is at present rarely obtained for more than four days in

Digitized by Google

seven, so that the head of the family only earns about 10*s.* a week; he is therefore anxious that his wife and children should increase this amount, and, though the youngest may not go down in the mine, they can work on the surface even at the tender age of seven. Living is cheaper in Belgium than in England, but the difference is not sufficient to enable the miners to live decently on such meagre wages. The women and children very generally work for 5*d.* a day, so that the financial advantage which is supposed to atone for the ruin of home life is very slender. If to these considerations we add the unwholesome nature of the toil in the damp and often poisonous atmosphere of coal-mines, it will not be difficult to explain the deplorable outburst of violence which has so recently shocked Europe. Where the Belgian workmen are well organised—as, for instance, at Ghent, where the light of education has elevated the toiling masses—there has been no violence, and the strikes, when they break out, are conducted in an orderly manner. But where there is no organisation, no education, and the population has degenerated physically through the exposure of women and children to excessive labour and insufficient food, reason loses its control over the body politic, and human beings are apt to act as herds of wild animals.

HYDROPHOBIA AND THE DOG REGULATIONS.

FRESH evidence of the value of the practice of muzzling dogs as a precautionary measure against hydrophobia comes from Vienna. The muzzling of dogs was practised there from 1879 to 1883, and during those years the number of cases of hydrophobia officially known was respectively 26, 23, 38, 5, and 2. In the year 1884 muzzling was abolished, and during that year 93 cases of bites from mad or suspected dogs are said to have been notified. It would be interesting, and would add to the value of the statement, if the number of cases of hydrophobia resulting from these bites were given. The very noticeable fall in the figures, however, from 38 in 1881 to 5 and 2 in the following two years bears witness to the usefulness of these precautionary measures. In Prussia by means of muzzling the number of cases of hydrophobia are said to have been reduced to a minimum. We trust that the new Chief Commissioner of Police, Sir Charles Warren, will in this matter continue the wise policy of his predecessor, for even were it proved beyond the shadow of a doubt that the bite of a rabid animal could be rendered incapable of conveying hydrophobia, or that the dire disease itself was a curable one, the clearing of the streets of London of ownerless and wandering curs would still be a boon to citizens, and an act of mercy and kindness to the wretched animals.

MARYLEBONE "DUST."

IF further evidence were required of the disgraceful condition of this parish with regard to the neglect of the sanitary authority to remove house refuse, it is to be found in the report of the last meeting of the Marylebone vestry, when a letter from the newly-appointed dust contractor was read. The contractor stated that when he entered upon his contract a few days ago, his foreman was given 273 complaints from householders of non-removal of dust, while the total number he had received in five days was 945; there was hardly a house which was not full of dust, and he was compelled to send out extra carts. A more discreditable condition it is difficult to imagine, and a more frivolous excuse—the death of the hall porter, who received complaints—it is impossible to conceive. That the most important part of the scavenging arrangements of a large and wealthy parish should be disorganised through the death of a person in this position is evidence of the failure of vestry government to undertake successfully any but the smallest duties. The vestry are themselves responsible for the removal of house refuse; they are permitted by law to depute the duty to other people, but they cannot acquit themselves of the responsibility, and the law which permits the scavenger to be fined for neglect should also make the vestry liable to penalty if they in their turn omit to exercise due supervision over his actions. The householder is absolutely in the power of this incapable body; he is not allowed under penalty to relieve his household of a standing danger by authorising any but the vestry's contractor to remove his dust, and if he should deposit it in the road he is liable to prosecution by the police; he is, moreover, compelled to pay heavy rates to the vestry, yet the only remedy he has against this body is that of complaint. The almost hopeless task of reconstituting the local authority so as to make the interests of the ratepayer superior to the interests of the contractor is too slow to be depended on, and under these circumstances we would gladly see householders agreeing to adopt the course which has been indicated by Mr. Cooke in his reply to Dr. Edis; but even this method will only assist individuals, and the only remedy for the parish as a whole worth the name is for the vestry not to trust to contractors, but to undertake the duty themselves.

"DEATH FROM IRRITANT POISONING."

SUCH was the verdict of a coroner's jury recently empanelled at Chesterton, Hunts, to inquire into the cause of death of two children aged six years and sixteen months respectively. From the evidence it appears that the deceased, their mother, and another child were taken suddenly ill after partaking of the same food. Dr. Stevenson of Guy's Hospital failed on analysis to detect any trace of poison, but he laid stress on the fact that a number of people were similarly and simultaneously affected. They had all eaten some food prepared from flour obtained by grinding some "dressed wheat," but there was no evidence to show that the dressing, usually arsenical, had caused the symptoms. The flour was dark in colour, and the starch granules were all formed, or had been deformed, by damp and subsequent drying. May it not have been that the wheat contained an admixture of seeds of some poisonous plant? We are not aware whether or not any other persons than those mentioned above partook of the food. This is an important point for consideration. In any case, the fact is worth noting that, with the aid of the highest skilled evidence, a coroner's jury have found that two children have died from irritant poisoning without any poison having been detected by chemical and physical tests.

A NOBLE ACT.

ONE of the latest, if not the latest, of the applicants for the benefits of M. Pasteur's assistance is Mr. Harris, a student of Charing-cross Hospital. Courage and self-devotion are virtues so frequently, we might indeed say so constantly, practised by members of our profession, that they come to be looked upon as commonplace and of every-day occurrence unless occasionally attention be drawn to them. Mr. Harris was taking luncheon at the restaurant of the Grand Hotel, when a dog which appeared affected with rabies attacked a lady there present. Mr. Harris seized the animal by the throat and got it safely out of the building, but in trying to twist his chain round him to render him incapable of inflicting injury, the young man, although the dog was muzzled, received a bite. He started on the next day with a friend to place himself under M. Pasteur's care, for the dog, being taken to the Battersea Home, died of rabies. We hope, whether by M. Pasteur's inoculation or by the percental immunity of bitten persons, Mr. Harris will not suffer for his bold and generous intervention

GAMBETTA'S BRAIN.

AT a recent meeting of the Anthropological Society of Paris a report by M.M. Duval and Chudzinski was read on the brain of M. Gambetta. The third frontal convolution was highly developed, the upper part of it being reduplicated. Reference was made to the brains of persons of low intelligence, and also to the prominence of Broca's convolution in the brains of Wulfert, the lawyer, and Huber, the philosopher, described by Rüdinger. In each of these latter *savants*, who were remarkable for their dialectical and rhetorical ability, the convolution was more wavy and complex than in ordinary brains, this being especially marked at the base, but there was no reduplication at the upper extremity of the convolution, as in Gambetta's. In the present case there were other indications that the brain was not that of an ordinary person. The right quadrate lobe was very complicated, and divided into two parts by a furrow branching off from the occipital fissure. Of these two parts, the inferior was divided into several little convolutions by a furrow with numerous stellate branches. The occipital lobe was very small, especially on the right side. Altogether the brain had a peculiarly fine appearance, due to its great and somewhat diagrammatic regularity, especially in the frontal region. The weight is to be discussed in a future paper.

PROFESSOR PETTIGREW, LL.D.

THE University of Glasgow has conferred the honorary degree of LL.D. on the Chandos Professor of Medicine of St. Andrews University, in recognition of his many labours in science and medicine. Few men of our day have more worthily won this honourable recognition than Dr. Pettigrew, His works on the "Valves of the Vascular System," on the "Muscular Tunics of the Heart," on the "Ganglia and Nerves of the Heart," and, above all, his researches on the various modes of flight, with his discovery of the now famous figure of 8 and wave theories of flying, place him amongst the most advanced scholars and original investigators of our day. We wish him long life for the enjoyment of this the latest of his many well-earned distinctions, and for the continued pursuit of his useful and valuable labours.

OVERCROWDING OF THE PROFESSION, AND MEDICAL ETHICS.

COMPLAINTS are frequently made in the Belgian medical journals of the overcrowded state of the profession in that kingdom, and of the frequency of serious breaches of medical etiquette to which this gives rise. It is stated that during the present year more than 200 students will be qualified and will have to seek to form practices for themselves, at the expense, of course, of established practitioners. In order to minimise the temptations to irregular and undignified methods of obtaining a *clientèle*, it is strongly urged that *cercles*, or local medical associations, should be formed wherever they do not already exist. It seems that a powerful and useful association has been for some time established in Verviers, and this is held up by *Le Scalpel*, one of the leading Belgian medical journals, as a suitable model on which other associations may be formed. Its rules, which have been largely borrowed from an older association at Antwerp, are as follows:—1. A practitioner summoned to a patient already under treatment cannot attend until the *confrère* previously in attendance has been informed. If this has not been done he must propose a consultation. 2. A practitioner called to a case of emergency occurring in a patient already under treatment should confine himself to giving such assistance as is necessary, and should leave a copy of his prescription for his *confrère*. 3. All the members of the association engage to act as substitutes for a *confrère* who is ill or on his holiday. This does not, however, hinder his making arrangements with some of them to attend his patients. 4. A practitioner absent or ill will notify to his *confrères* the time when he will resume his practice, and they will immediately send him a list of the patients they have attended, with any information they may consider desirable. 5. It is a point of honour with a practitioner not to retain patients belonging to a *confrère* who is ill or absent. 6. Another duty of the practitioner is to abstain from expressing an unfavourable opinion of, and from making unkind insinuations about, the treatment employed by a *confrère* who has preceded him. 7. A practitioner who succeeds another must not permit himself to accept a lower visiting fee than his predecessor. 8. The consultant cannot succeed the practitioner in charge until he has informed him in writing of the distinct wish declared by the patient that he should do so. 9. The practitioner should leave to the patient the choice of a consultant and accoucheur, and should not depart from this rule unless he is particularly requested by the family to name one himself. 10. The only practitioner with whom a consultation may be declined is one who is excluded from the Association.

HYSTERIA IN SOLDIERS.

DR. A. T. OZERETSKOVSKI describes in the Russian *Medical Review* a whole series of cases of hysteria occurring in soldiers, presenting nearly all the phenomena usually associated with this affection as it occurs in females —dumbness, deafness, deaf-mutism, various disturbances of vision and of general condition, spasms and paralyses, troubles connected with micturition, joint trouble, elevations of temperature, &c. The subsequent history of the cases in most instances left no doubt of the correctness of the diagnosis. Predisposition and heredity played a large part in the etiology, and in some instances there was injury or shock. Half the patients were recruits, which tends to show that the sudden change from domestic life and work to the arduous conditions of military service is not without effect on the nervous condition of the Russian soldier. The treatment of the hystero-epileptic cases was always unsuccessful, neither water, electricity, nor narcotics appearing to exert any influence over the frequency or severity of the attacks. The cure of the paralytic forms of the disease was successfully accomplished by means of exercise, gymnastics, &c.

THE LATE MR. FORSTER, M.P.

THE medical profession has lost by the death of Mr. W. E. Forster one of the few members of the House of Commons who have taken a broad and comprehensive view of the need of reform in the profession, both for its own sake and for that of the public. In the past he had proved himself a true friend, and we most sincerely regret that he has not been spared to witness in a future which as yet seems somewhat "dim and distant" the accomplishment of a truer and more satisfactory medical reform than appears probable at present.

THE GROCERS' COMPANY AND PATHOLOGICAL RESEARCH.

TWO lectures will be given next week in the theatre of the University of London by gentlemen who have been engaged as "Research Scholars" of the Grocers' Company in pathological investigations. The first of these will be on Tuesday next, at 5.30 P.M., when Dr. Wooldridge will give an account of several important discoveries of great pathological interest as to the Coagulation of the Blood. The second lecture will be given on Thursday by Mr. Lingard on the Etiology of Typhoid Fever.

M. PASTEUR'S INOCULATIONS.

AT the extraordinary meeting on the 4th inst. of the Accademia Medica di Roma, under the presidency of Professor Guido Baccelli, the discussion on the new method in hydrophobia was resumed by Dr. Marchiafava, who was followed by Drs. Brunelli, Carruccio, Colasanti, Durante, Scalzi, Gualdi, Bastianelli, and Piermarini. Dr. Carruccio's contribution to the debate had the special merit of calling attention to the important experiments on the nature and treatment of hydrophobia conducted in 1810 by the able physician, Dr. Agostino Cappello of Tivoli. The proceedings came to a close with a resolution, unanimously voted, to the following effect:—"The Academy has decided to send to Paris a competent representative to study the Pasteur methods. With this object it empowers the President to ask for the necessary funds from the Ministries of the Interior and of Public Instruction, and from the Municipality." The next number of the *Bollettino* will contain a revised report of the discussion.

ARMY MEDICAL SCHOOL.

SIXTY surgeons on probation for the British Medical Service, and sixteen for the Indian Medical Service, met at Netley on the 1st inst. to attend the summer session of the Army Medical School. The introductory lecture was delivered on the following day by Professor Boyes Smith, who drew largely from his wide field of Indian experience for the subjects of his discourse. The talented lecturer, in the course of his address, paid a very eloquent tribute to the valuable services of his predecessor in the chair, Professor Maclean, in advancing tropical medicine, and dwelt with much feeling on the kind and ready help the Professor had afforded him when entering upon his new sphere of duty in the school. The large number of seventy-six surgeons sent to go through the present session has caused some difficulty in providing the necessary accommodation, and a certain proportion have been lodged in different houses in the adjoining village of Netley.

IMMORAL CONDITION OF THE LONDON STREETS.

THE committee appointed by the London Diocesan Conference to investigate and report on this important subject has not been able to add to the information already possessed, nor, so far as we can see, to make any useful suggestion. It is no reflection on the ability and energy of the committee to pronounce this judgment on the result of its labours. As a matter of fact, there is not much room for further inquiry, and there would seem to be little chance of good being done by directing attention to the subject. The committee is of opinion "that the continental system of a 'police des mœurs' would not commend itself to English feeling." Until something of this sort is adopted in England there is practically no hope of amendment.

UNQUALIFIED PRACTICE AT SHEFFIELD.

THE Sheffield Coroner has been making some very proper remarks on the subject of unqualified practice, in connexion with a case in which a boy was attended by a practitioner whom his parents thought qualified, but who was not so. This, he justly said, was attending people under a false pretence. It is, indeed, a very serious and culpable practice, which coroners do a great service in exposing. The coroner spoke in something like a tone of complaint that the Medical Society (*sic*) did not prosecute such cases, which he had communicated to the Society. But we should like to point out to the coroner that the duty of prosecuting an unqualified practitioner belongs really to the police or public authorities, and not to medical men. It is the public who suffer, and the prosecution by medical men is more or less invidious. We offer him, however, and all coroners who bring such cases to light, our hearty thanks.

CHANGES IN FOREIGN PROFESSORSHIPS.

DR. N. BOGOLYUBOFF, Extraordinary Professor of Surgery in the University of Kazan, has been appointed to the vacant Professorship of Surgery in the same university. Dr. Oscar Eversbusch, privat docent in Munich, has been appointed Professor of Ophthalmology in Erlangen. Dr. Kessel, privat docent in Gratz, has been appointed Professor of Otology in Jena. Dr. Grawitz, second assistant in the Berlin Pathological Institute, has been appointed Professor of Pathological Anatomy in Greifswald, in the place of Professor Grohe, whose resignation has been caused by ill health.

ROYAL UNIVERSITY OF IRELAND.

A MEETING of Convocation of this University was held on Tuesday last, the 6th inst., to elect a member of the Senate in the vacancy which had occurred by the expiration of Mr. Farrelly's term of office. Mr. Farrelly was opposed by Dr. Thomson, surgeon to the Richmond Hospital, the result of the election being that the latter gentleman was returned by a majority of three votes, the voting being 251 for Dr. Thomson, and 248 for Mr. Farrelly.

MR. SAVORY.

WE understand that Mr. Savory, President of the Royal College of Surgeons, has been offered a knighthood, an honour which he has declined to accept.

AN important paper was on Sunday last submitted to the Accademia dei Lincei of Rome by Professor Tommasi-Crudeli on "A Bacillus found in the Malarious Atmospheres of the Environs of Pola (in the Istrian Triangle)." The paper was accompanied with ten microscopic preparations by Dr. Schiavuzzi, and will shortly be published in the Academy's Transactions.

DR. OLIVER WENDELL HOLMES will leave Boston for Europe during the present month, and will pass the summer on this side of the Atlantic. It is just fifty years since he last visited Europe.

"A UNIVERSITY for Birmingham" is a project under discussion by the teaching staffs of Queen's and Mason Colleges.

Pharmacology and Therapeutics.

ANTIPYRIN IN OPHTHALMIC PRACTICE.

SOME observations by Khomyarkoff and L'voff (*vide* THE LANCET, Jan. 30th), tending to show the superiority of antipyrin over salicylate of soda in articular rheumatism and migraine, having induced a Russian ophthalmic surgeon, Dr. T. N. Katsauroff, to try it in cases of ciliary neuralgia and headache accompanying various eye diseases, he has published the results of this method of treatment in the *Vrach*. The patients comprised seventeen males and ten females, their ages varying from seventeen to seventy-five. Apart from the eye affection, all but three were free from disease. The antipyrin was always given in doses of a gramme (fifteen grains), and in every case appeared to be of distinct benefit in relieving the pain, a single dose being sufficient in fourteen cases, while in thirteen cases this had to be repeated, in two of them only (optic neuritis and scleritis) a third dose being found requisite. The author mentions that in nine cases where

Digitized by Google

operations for cataract had been performed and the enforced subsequent dorsal position proved so irksome as to induce headache, the antipyrin seemed particularly valuable, though two of them were complicated by iritis. The action of the drug in these cases was rapid, an improvement generally taking place in half an hour, and the pain being completely relieved in an hour. More or less satisfactory results were obtained in ciliary and cephalic pain accompanying different forms of keratitis, of which there were four cases; in corneal ulcers, of which there were three cases; and in glaucoma, of which there were ten cases. The drug seemed, however, to have less effect on a case of double neuritis, on two of atrophy of the optic nerve, and on one of scleritis. As observed by Khomyarkoff and L'voff, antipyrin proved very valuable in Dr. Katsauroff's hands in migraine, his case being of traumatic origin, a foreign body having penetrated the soft structures of the orbit. Previously to using antipyrin as described, Dr. Katsauroff had been in the habit of employing salicylate of soda in cases of headache accompanying eye diseases, but he found that it was often necessary to give it in such large doses as to cause singing in the ears, whereas no unpleasant effects were produced by antipyrin in any of his cases.

HELENIN IN DIPHTHERIA.

Dr. Juan Beltrán Obiol has communicated to *La Cronica Médica*, a paper on the subject of the successful treatment of diphtheria by means of helenin. He refers to a work by Dr. E. Pilatte, published in Paris and entitled "Recherches expérimentales sur le Bacile de la Tuberculose," in which it is stated that the three substances most destructive to cultivations of bacilli are, in the order of their activity—(1) Sulphuretted hydrogen; (2) corrosive sublimate; (3) helenin. The first two of these are of course out of the question for diphtheria. Helenin, therefore, is the only one which can be used for this purpose. Dr. Obiol is very particular about the helenin he employs, for he finds many specimens in the market which are exceedingly impure. When pure, he says, it is perfectly white and flocculent, like sulphate of quinine. It has an aromatic odour and a bitter aromatic taste. It is insoluble in water, and does not communicate to it any opalescence. It is very soluble in alcohol, and even more so in ether, the solutions being clear, colourless, and depositing no sediment. It is also soluble to the extent of 2 per cent. in oil of sweet almonds. Impure specimens are apt to be granular, heavy, yellowish, only slightly bitter, with a resinous odour, and they sometimes impart opalescence to water, and deposit a precipitate from their solutions in alcohol and ether. Another substance sold as helenin, but which is said to be a derivative of shalin and not to possess the antiseptic properties of helenin, is crystalline, only slightly soluble in ether and alcohol, and not at all in oil of sweet almonds. The pure drug is ensured by prescribing "helenin (Baeza)." The author's plan was to apply powdered camphor on the end of the finger to the diphtheritic patches, and then to paint them over with a solution of helenin in oil of sweet almonds. This was done at first every four hours, and quickly produced complete destruction of the false membrane. The drug was also given internally in doses of one grain and a half to children of six years of age, care being taken to administer the powder after the application, as the latter sometimes induced vomiting. The author had great success with this method of treatment, but he insists on the necessity of the local applications being made by the medical man himself as far as possible, and not left to the parents. He found that when he commenced the treatment on the first day of the disease, a single day was sufficient to effect a cure; when he commenced on the second day, two or three days were required; when on the third or fourth day, from six to nine days were needed; but when he did not see the patient till the fifth or sixth day the hope of effecting a cure was not very great. In his experience albuminuria did not occur. The only unpleasant action of helenin is its constipating effects, against which it is necessary to guard by giving laxatives.

BINOXIDE OF NITROGEN IN CHOLERA.

Most persons who have dabbled in electrical science are aware of the unpleasant fumes emanating from batteries containing nitric acid. These, however, are said by a Spanish Professor to be an admirable preservative against cholera, it being noticed that none of the workmen employed in an electrotype establishment in Madrid where they were subjected to the fumes of the oxides of nitrogen died from cholera during the epidemics of 1834, 1859, and 1865, and that only such of the workmen as were, absent frequently from the factory were attacked at all. He has also ascertained that liquids from dead bodies, on being treated with binoxide of nitrogen, soon lose their peculiar smell and remain quite free from micro-organisms. A French naval surgeon also has made use of the binoxide in thirty-five cases of cholera, with very satisfactory results. On the whole the Professor predicts that this substance will prove a most important general disinfectant, and a valuable means both of preventing and treating cholera.

SULPHATE OF THALLIN.

Dr. Britneff, having investigated the effect of sulphate of thallin in fifteen febrile cases—pneumonia, tuberculosis and typhus,—has come to a conclusion similar to that reported by Jaksch, Guttmann, and others—viz., that, though thallin is an active antipyretic, its effects are of short duration, the temperature generally rising soon afterwards with a rigor. He does not expect, therefore, that it will be found of much use in medicine.

ALKALOIDS OF LOBELIA.

Two alkaloids, one liquid and corresponding to lobeliine obtained from Lobelia inflata, the other solid, crystalline, soluble in chloroform, have been discovered by Dr. v. Rosen in Lobelia nicotianæfolia. He also detected the second alkaloid in Lobelia inflata. Lobeliine hydrochlorate, lobeliine sulphate, and the solid alkaloid correspond in their pharmacological characters, and resemble apomorphia in producing emesis.

"SACCHARINE."

An ill-chosen name for a very sweet coal-tar derivative, for the term has hitherto belonged to an altogether different body. "Saccharine" is benzoyl-sulphonic-imide, and can be artificially prepared. It has an intensely sweet taste, and the possibility of its displacing cane sugar makes it interesting; Dr. Stutzer of Bonn has asserted that the new principle is absolutely innocuous in the system, from which it is speedily eliminated by the urine.

TOXIC PROPERTIES OF SASSAFRAS.

An interesting paper by Dr. J. Bartlett of Chicago has been published in the *Pharmaceutical Journal* on the toxic properties of sassafras. It appears to have some resemblance to three familiar drugs—opium, strychnine, and ergot; for it has a narcotic and sudorific action; a property of inducing tetanic and clonic spasms, followed by paralysis and a probable stimulant effect on the muscle of the uterus.

FRANCISCEINE.

Francisceine, according to the *British and Colonial Druggist*, is proposed as the name of a new alkaloid which has just been extracted from the Brazilian manaca root, the produce of the Franciscea uniflora and certain other species. The principle in question has a very powerful purgative and diuretic action, and is also possessed of diaphoretic and emmenagogue properties.

AREKANE.

Arekane resembles nicotine and has been obtained by E. Bombelon from the "betel nut." It is a colourless volatile oily alkaloid, smelling like weak meat bouillon, and has a strongly alkaline reaction. It increases the secretion of the salivary glands, retards the pulse, and exercises a purgative action.

BOARDING-OUT OF PAUPER CHILDREN.—On the 6th inst., at a meeting at Exeter Hall, an Association was inaugurated having for its object the promotion, in concert with boards of guardians and others, the boarding out of orphan and deserted children; the formation of a link of communication between boards of guardians wishing to board out such children, and others included under the Local Government Board Order of 1870, and certified boarding-house committees willing to receive them; also the facilitating exchange of information between the several boarding-out committees, and an inquiry into the operation of the various systems of boarding out, and general co-operation in all measures for the promotion of boarding out, and for the welfare of the children thus provided for. Lord Cranbrook was elected president of the Association, and amongst the vice-presidents were the Archbishop of Canterbury, Cardinal Manning, and Mr. Goschen.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

King's Norton Rural District.—This district had in 1885 the low death-rate of 12·9 per 1000, the zymotic rate only reached 0·4, and the rate of deaths amongst infants under one year per 100 births was only 10·6. There was no death from small-pox, and the vaccination returns show that of 655 children due for vaccination only one remains outstanding. A few cases of diphtheria and of enteric fever occurred, and where these were associated with insanitary conditions remedial action was taken. Many improvements have been effected since the last report in the drainage and water-supply, and further works are still in progress. The sanitary hospital has well served its purpose of preventing the spread of disease, but it is only a temporary structure. The night-soil removal is very properly not imposed on the inhabitants; but being done by private contract, it is still not quite satisfactory. The disgusting practice of tipping the refuse into the road and then shovelling it into carts should be put down with a strong hand, and the authority had better adopt the model bye-laws on the prevention of nuisances which deal with this practice. But, on the whole, Mr. Hollinshead may be congratulated on the state of his district.

Swinton Urban District.—In this district scarlet fever became somewhat widely prevalent during the past year, and Mr. W. M. Jones points out how difficult it is to control such a disease when the first cases are kept secret from the sanitary authority. The Local Board of Health, by offering a fee for each case reported, afford an inducement to report every case; but yet this outbreak was allowed to get a firm hold on the affected locality without a single case being reported. This failure of a voluntary system of notification is by no means exceptional, and even the refusal of a single practitioner to comply with the wishes of the authority has more than once led to an entire break-down in the system. But in Swinton more is wanted than information as to spreading diseases—namely, some means for their isolation. When this is provided it will be time enough to call for compulsion in the matter of notification. Drainage works are still in progress, and the water-supply of the district is excellent.

Todmorden Urban District.—Mr. Charles Thorp recommends night scavenging. As to this we would suggest perusal of the model bye-law of the Local Government Board dealing with this subject, and of the comments on it in the annotated edition of the bye-laws. It is there pointed out that hitherto the construction of privies and receptacles for filth and refuse has very generally been such as to ensure rapid decomposition and consequent offensiveness of contents, and on this account it has been a frequent practice to require such structures to be emptied at night. This is, however, precisely the time not only when the scavengers themselves cannot see to do their work properly, but when they are least likely to be subjected to any proper supervision. Hence needlessly offensive operations are likely to be carried out. It is also the only time when persons desirous of absenting themselves during the process of scavenging are practically unable to do so. So also the period of sleep is that during which the human system is least able to resist the influence likely to result from the inhalation of noxious effluvia. And further, the more the conditions resulting from faulty structures are brought to light, the more likely are they to be remedied. For these and other reasons, scavenging under cover of darkness should be avoided. The death-rate for the district in 1885 was 17·3, and that from zymotic diseases 0·78, per 1000. The isolation hospital was useful in staying the spread of scarlet fever.

Towyn Urban District.—In a population of 3450, the death-rate for 1885 was 17·6 per 1000, which is not low for so small a population. Dr. Grosholz reduces it to 16·8 by deducting the deaths of prematurely born children; but obviously such a reduction makes the statistics valueless for the purposes of comparison, unless the same reduction were made everywhere else. No single case of sickness was heard of from either enteric fever or from diphtheria, but measles led to the temporary closing of the elementary schools. A curious epidemic of diarrhœa occurred in this district, beginning in Towyn, then creeping up the Dysynni valley to Aberganolwyn, and finally expending itself in Aberdovey. No single circumstance, such as water-supply &c., seems to have been common to those affected, and these were in many instances adults. Such outbreaks call for very searching investigation, but in this instance the actual cause was not made out. Towyn stands in great need of a proper system of sewerage and water-supply.

Aston Urban District.—The death-rate for this district has for some five years ranged from 12 to slightly over 14 per 1000, and stands now at the latter figure; but the infantile deaths are not so satisfactory, amounting as they do to 14 per year of every hundred children born. Scarlatina alone prevailed as an epidemic; and in this connexion it is noteworthy that the opening of an excellent hospital for infectious diseases has been one of the prominent features of the year. The sanitary authority have also determined to make an effort to secure early information as to cases needing isolation, by organising a system of voluntary notification at a fee of half-a-crown per case reported. Improvements in water-supply, sewer-ventilation, and methods of house-drainage are being effected, and the additional action needed to place the district in a satisfactory state is indicated by Dr. Bostock Hill in his report. Diagrams are also appended showing a new ventilating manhole, and details as to house-drainage; these cannot but be extremely useful to builders and to the public generally.

Llanelly Rural District.—In reference to a prevalence of scarlet fever, Dr. Raglan Thomas reports that in the Berwick hamlet much time was lost, by lack of information, in isolating the first attacks, and that the school authorities did not for some months comply with the request to close certain schools. It cannot be too widely known that under the revised Education Code the authorities of all schools coming within the provisions of that code have no alternative but to close schools on the instruction of the sanitary authority of the district, and also that, though appeal may be made to the Education Department, yet this does not enable the school officials to keep the schools open pending the appeal. The tabulated account of prevalent disease, its causes, extent, and the resulting sanitary action embodied in this report show that active work is maintained in this district, which in 1885 had a mortality at the rate of 15·33 per 1000. During the year, and with a view to any cholera emergency, a hospital hut was provided.

Taunton Urban and Rural Districts.—Considerable improvement in the water-supply of the *urban district* was effected during the year; but the private fittings, and notably the cisterns, call for further attention. Thus, Dr. Alford says that drinking-water is even drawn directly from a pipe discharging into the pan of a dirty closet. Closet supplies should always be drawn from separate cisterns, and if the service be a constant one no other cisterns are needed. The need for efficient ventilation and flushing of the town sewers has several times been commented on, especially in connexion with diphtheria, and we fear that even now the construction of the sewers remains faulty; if so, lodgment of contents is certain, and no ventilation and flushing should be regarded as superseding the necessity for reconstruction of such portions as are found to be faulty. The death-rate for Taunton reached 23·6 per 1000 during the past year, and the zymotic rate was no less than 3·7 per 1000. Fourteen deaths took place from small-pox, the disease prevailing in some dwellings built back-to-back in dark courts and alleys, with garbage, manure, filthy premises, and closets around; a state of things which needs the active interference of the sanitary authority. Measles and scarlet fever also prevailed. It is evident that there still remains ample scope for the labours of the energetic officer of health, who has already done much for Taunton. In the *rural district* the death-rate was also very high, reaching as it did over 18 per 1000; and the zymotic rate, too, was no less than 2·6 per 1000—small-pox, measles, and diphtheria being main contributors to it. In a number of places in this district there are old and imperfect sewers and drains, accompanied with stagnant and decomposing surface-slops. The water-supply also remains far from satisfactory, shallow wells being the rule, and these are often in most dangerous proximity to privies and piggeries. The past history of these two districts in relation to diphtheria should have led before this to more intelligent action, with a view to remedial measures being adopted on a wide and comprehensive scale. Many nuisances are well looked after, good advice is given, and the sanitary hospital works well. But

Digitized by Google

more than this is needed for the due protection of life and health.

Windsor Urban District.—Dr. Casey reports that the death-rate for this district during 1885 was 18·6 per 1000 on a population of 12,493, a fatal epidemic of measles having helped to increase the mortality. It is, however, satisfactory to note that a single death from enteric fever was the only one that had taken place from that cause during a period of five years. In connexion with the work of the year it is stated that samples from eight wells were submitted for analysis and condemned, and that twenty-four houses were, at the instance of the authority, furnished with a supply from the mains. It is astounding to think of the ignorance of the owners of "private" wells which are sunk in the soil of this ancient borough, honeycombed as it has been in the past with cesspools leaking on all sides; but it remains a fact that people in Windsor still draw their water from the same source as that into which their ancestors poured their filth. Only two houses were closed during the year, and the report dealing with this question points to the evils connected with leasehold tenure, a lessee being naturally most unwilling to go to any expense in improving a property in which he will in a few years lose all interest. This is true, but leases can hardly be abolished, and sanitary authorities are constituted in order to see that persons having a financial interest—however limited—in property shall not so use, and profit by, that property as to prejudice the public health.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6052 births and 3862 deaths were registered during the week ending April 3rd. The annual death-rate in these towns, which had been equal to 29·3 and 26·4 per 1000 in the preceding two weeks, further declined last week to 22·2. During the thirteen weeks ending last Saturday the death-rate in these towns averaged 24·4 per 1000, and precisely corresponded with the mean rate in the thirteen corresponding weeks of the ten years 1876-85. The lowest rates in these towns last week were 12·4 in Wolverhampton, 15·6 in Sunderland, 15·9 in Norwich, and 18·8 in Hull. The rates in the other towns ranged upwards to 27·9 in Plymouth, 28·7 in Brighton, 28·8 in Bolton, and 31·4 in Blackburn. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 430, 427, and 406 in the previous three weeks, further declined last week to 359; they included 157 from whooping-cough, 97 from measles, 36 from diarrhœa, 30 from "fever" (principally enteric), 19 from scarlet fever, 19 from diphtheria, and only 1 from small-pox. No death from any of these zymotic diseases was recorded last week in Norwich, Wolverhampton, or Huddersfield; whereas they caused the highest death-rates in Bolton, Birmingham, and Blackburn. The greatest mortality from whooping-cough occurred in Newcastle-upon-Tyne, London, Portsmouth, and Birkenhead; from measles in Portsmouth, Oldham, Birmingham, Plymouth, and Blackburn; and from "fever" in Preston. The 19 deaths from diphtheria in the twenty-eight towns included 8 in London, 2 in Bristol, and 2 in Manchester. Small-pox caused 1 death in Liverpool, and not one in London and its outer ring, or in any of the twenty-six other large English towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 7 and 8 on the preceding two Saturdays, had further increased to 11 at the end of last week; 4 cases were admitted to these hospitals during the week, against 2 and 5 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 917 and 710 in the preceding two weeks, further declined last week to 506, and were 30 below the corrected weekly average. The causes of 83, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Brighton, Leicester, Plymouth, Derby, and Huddersfield. The largest proportions of uncertified deaths were registered in Oldham, Sheffield, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 27·9 and 24·7 per 1000 in the preceding two weeks, further declined to 21·6 in the week ending April 3rd, and was 0·6 below the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 11·5 and 14·1 in Perth and Leith, to 22·5 in Paisley and 25·5 in Glasgow. The 534 deaths in the eight towns showed a further decline of 75 from the numbers returned in the preceeding two weeks, and included 14 which were referred to whooping-cough, 11 to diarrhœa, 5 to "fever" (typhus, enteric, or simple), 5 to diphtheria, 4 to scarlet fever, 4 to measles, and 3 to small-pox; in all, 46 deaths resulted from these principal zymotic diseases, against 46 and 62 in the preceding two weeks. These 46 deaths were equal to an annual rate of 1·9 per 1000, which was 0·2 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 20, 14, and 29 in the previous three weeks, declined again last week to 14, of which 12 occurred in Glasgow. The 11 deaths attributed to diarrhœa corresponded with the number in the previous week, but were 6 above the number in the corresponding week of last year. The 5 deaths from "fever" exceeded the number in the previous week by 1, and included 2 in Edinburgh and 2 in Paisley. The deaths from diphtheria, which had been but 1 in each of the previous two weeks, rose last week to 5, of which 2 occurred in Aberdeen. The 4 fatal cases of scarlet fever were returned in Glasgow, and the 4 of measles in Edinburgh. The 3 deaths referred to small-pox included 2 in Leith and 1 (certified as chicken-pox) in Aberdeen. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 204 and 148 in the preceding two weeks, further declined last week to 134, but were 4 above the number returned in the corresponding week of last year. The causes of 80, or 15 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 40·5 and 34·6 per 1000 in the preceding two weeks, further declined to 34·4 in the week ending April 3rd. During the thirteen weeks ending last Saturday the death-rate in the city averaged no less than 33·5 per 1000; the mean rate during the same period did not exceed 24·8 in London and 20·0 in Edinburgh. The 233 deaths in Dublin last week were within one of the number returned in the previous week, and included 15 which were referred to the principal zymotic diseases, against 19, 13, and 18 in the previous three weeks; 6 resulted from whooping-cough, 5 from "fever" (typhus, enteric, or simple), 3 from scarlet fever, 1 from diarrhœa, and not one either from small-pox, measles, or diphtheria. These 15 deaths were equal to an annual rate of 2·2 per 1000, the rates from the same diseases being 2·3 in London and 1·4 in Edinburgh. The fatal cases of whooping-cough, which had been 6 and 12 in the preceding two weeks, declined again last week to 6. The deaths referred to "fever," on the other hand, rose again to 5, from 6 and 1 in the previous two weeks. The 3 fatal cases of scarlet fever showed an increase upon recent weekly numbers. Two inquest cases and 3 deaths from violence were registered; and 74, or nearly a third of the deaths, were recorded in public institutions. The deaths of infants were more numerous than in the previous week, whereas those of elderly persons showed a marked decline from recent weekly numbers. The causes of 39, or nearly 17 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Coldstream Guards: Surgeon Robert Hippisley Cox, Medical Staff, to be Surgeon, vice J. Magill, M.D., promoted.

ARMY MEDICAL STAFF.—Surgeon-Major Hubert Rothwell Greene, from the Seconded List, to be Surgeon-Major. The undermentioned Surgeons-Major are granted retired pay, with the honorary rank of Brigade Surgeon: Hubert Rothwell Greene, John Fitzgerald Brodie, Vivian Wearne.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon William Middleton Power has been placed on the Retired List of his rank.

The undermentioned surgeons have been promoted to the

Digitized by Google

rank of Staff Surgeon in Her Majesty's fleet: William Henry Patterson, Everard Home Saunders, Henry Anthony Wills Richardson, James Alexander Collot, Edward Wentworth Luther, Robert Bentham, Nicholas Crawford Ross, William Edward Bennett, James William Hambly Hawton, and Edward Ross Mulock.

The following appointments have been made:—Staff Surgeons J. B. Drew and T. O'Sullivan, to the *President*, additional, for service at the Royal Victoria Yard, Deptford; Fleet Surgeon G. Maclean, to the *Alexandra;* Surgeon J. Crowley, to the *Excellent;* Surgeon H. L. Crocker, to the Royal Naval Hospital, Chatham; and Surgeon J. J. Walsh, to the *Excellent*, additional.

YEOMANRY CAVALRY.—Lancashire Hussars: Surgeon E. H. Beaman, whose resignation has already been notified, is granted the honorary rank of Surgeon-Major, and is permitted to wear the uniform of the regiment on his retirement.

ARTILLERY VOLUNTEERS.—1st Argyll and Bute: J. Hunter and W. Hunter are granted the honorary rank of Surgeon-Major.—1st Devonshire: Surgeon G. Pycroft is granted the honorary rank of Surgeon-Major.—1st Glamorganshire: Surgeon F. W. Granger is granted the honorary rank of Surgeon-Major.—1st Lanarkshire: Surgeon J. Provan, M.D., is granted the honorary rank of Surgeon-Major.—2nd East Riding of Yorkshire: Acting Surgeon F. R. Chapman resigns his appointment.—1st West Riding of Yorkshire: Surgeon J. W. Scarth to be granted the honorary rank of Surgeon-Major.

RIFLE VOLUNTEERS.—1st Ayrshire: Surgeon J. McAlister is granted the honorary rank of Surgeon-Major.—5th Cheshire: Surgeon S. H. Munro, M.D., is granted the honorary rank of Surgeon-Major.—2nd Derbyshire: Surgeon W. Milligan is granted the honorary rank of Surgeon-Major.—2nd Forfar (Angus): J. Mackie, jun., M.D., W. F. Murray, J. K. Anderson, M.D., and G. P. Alexander, are granted the honorary rank of Surgeon-Major.—1st Lanarkshire: Surgeon A. K. Irvine, M.D., is granted the honorary rank of Surgeon-Major.—3rd Lanarkshire: Surgeon J. Dunlop, M.B., is granted the honorary rank of Surgeon-Major.—4th Lanarkshire (Glasgow 1st Northern): Surgeon R. Smart, M.D., is granted the honorary rank of Surgeon-Major.—6th Lanarkshire: Surgeon D. Maclean, M.D., is granted the honorary rank of Surgeon-Major.—4th Lancashire: Surgeon E. H. Roe is granted the honorary rank of Surgeon-Major.—1st Shropshire: Job Edwin Brooks, Gent., to be Acting Surgeon.—3rd Volunteer Battalion (the South Wales Borderers): John William Davies, Gent., to be Acting Surgeon.—6th (West) Suffolk: Harry Charles Costello Shaw, Gent., to be Acting Surgeon.—1st West Riding of Yorkshire: George Richard Green, Gent., to be Acting Surgeon.—2nd Volunteer Battalion, the Duke of Wellington's (West Riding Regiment): Surgeon J. E. Foster is granted the honorary rank of Surgeon-Major.

"Audi alteram partem."

SUPRA-PUBIC *v.* PERINEAL LITHOTOMY.

To the Editor of THE LANCET.

SIR,—As circumstances prevented me at the last moment taking part in the discussion of the above subject at the Medico-Chirurgical Society, I shall feel obliged, having regard to the great importance of the subject, if you will kindly allow me space to express the views I intended giving utterance to after reading the abstracts of the cases which preceded the discussion.

In Mr. Rivington's case the importance of providing for drainage of the bladder after lithotomy, where the stone is large, is clearly shown; and though terminating fatally, it seems to me to afford some evidence of the value of the perineal incision, in addition to the supra-pubic, as providing a suitable outlet in cases where the floor of the bladder is much depressed by what has been lodging there. Though I cannot come to the same conclusion as Mr. Jacobson that the supra-pubic operation is likely to find much more favour in the future than it has in the past, I think with him that probably some surgeons who have only rarely to operate for stone—or, I would add, who have not met with much success with the lateral operation—may find it easier and safer than the latter proceeding. Mr. Barwell, in one of his cases, illustrates what I believe to be the best practice in females where the stone cannot be removed by lithotrity and evacuation—namely, the adoption of the supra-pubic method in preference to dilatation of the urethra and extraction, as the latter is so frequently followed by incontinence of urine. Passing, however, from these interesting examples to the general question as to the position which supra-pubic lithotomy should hold in relation to the treatment of stone, I think there is a good deal to be said. My personal experience of supra-pubic lithotomy has been so limited that I should not venture to speak of it did I not feel that, though small, it related to the consideration of the whole subject of removing those stones from the bladder which lithotrity could not be made to include. On the other hand, my experience of lateral lithotomy has not only been considerable, but has given results which make me view with some apprehension the proposal to revive, with what seems to me but little discrimination, the supra-pubic operation. Whilst admitting all the advantages claimed for Petersen's method, I would still limit its performance to those cases beyond the reach of lithotrity, where the relations of the stone to the pubic arch were such as to render extraction by this way without damage to the adjacent parts obviously hazardous, and in the female to those cases where Bigelow's proceeding was inapplicable. I do not think it possible to define closer than this.

My reasons for urging that the supra-pubic operation should be reserved for those stones which in our individual judgment appear to be beyond removal, with safety to the surrounding parts, by the perineal method, partly arise from a consideration of some of the conditions under which Petersen's operation may be performed, and the experience we possess already relative to the performance of lateral lithotomy as at present practised. Of all the contingencies an operator has to calculate upon and provide against, the most embarrassing is the consciousness that he may find such an anatomical disposition of the parts as to render the completion of the contemplated proceeding impossible. The reflection of the peritoneum has been found so low down as to render it impossible to open the bladder without entering the peritoneal cavity.[1] I cannot recall any contingency of this nature which might not be provided against beforehand that has ever led to the lateral operation having to be abandoned. Again, I do not think that Petersen's operation is entirely without special dangers other than those connected with an abnormal reflexion of the peritoneum. Our experience of Petersen's method has so far been comparatively limited. Let me illustrate my point in another way. A patient with a stricture and a distended bladder was placed on the operating table of Bellevue Hospital for the purpose of having his stricture relieved.[2] Whilst struggling under ether the abdominal tumour suddenly disappeared, and the former area of dulness became tympanitic. At a post-mortem examination the bladder was found ruptured, without ulceration or other alteration. No doubt the distension in this case was considerable, as two quarts and a half of bloody fluid were found in the abdomen. When, however, we consider the condition of distension, so far as both the bladder and rectum are concerned, in Petersen's proceeding, I cannot think, from the descriptions I have read, that we are entirely free from the possibility of such an accident occurring in the case of an atonic or weakened bladder which might have not been realised beforehand.

Passing now to our experience of lateral lithotomy, let us see for a moment what is our position. In young male children a well-executed lateral lithotomy may be regarded as an extremely safe operation. Many surgeons I could mention have practised it a considerable number of times without a fatal result. It leaves no permanent weakness or imperfection behind. Why should we wish to change it other than on the somewhat questionable ground that to some the change may prove more convenient? Passing to the adult, we are left in the present day, thanks to the progress lithotrity has made, with a small residuum of cases which this operation cannot cover. And this residuum is practically made up of three groups of cases: (1) cases where the stones are too large to come out except through the abdomen; (2) cases of stone where the condition of the prostate is such as to demand some special attention:

[1] Polaillon: THE LANCET, Jan. 30th, 1886. Autal: Medical Chronicle, March, 1886.

[2] Dr. Cruise: New York Medical Record, Aug. 1st, 1881.

Digitized by Google

(3) cases of stone complicated with diseased or distorted bladders requiring drainage. I do not think that examples of these three conditions will be wanting in the practice of most surgeons. Of these three groups the first is provided for by supra-pubic cystotomy. I have already brought before the Society[3] two cases illustrating the second class, where patients were relieved not only of the symptoms which stone caused, but also of those produced by these large growths. Both patients are now alive and well, though several years have elapsed since these operations were performed. I have recently laid before the profession a record of cases[4] where I have been able to treat advantageously this frequent complication of stone in the bladder. Passing to the third class of cases, where the bladder requires not only the removal of the stone but draining, I would illustrate this in the following way. During the last two years two patients came under my care, one who had undergone the crushing operation twice and the other thrice, at comparatively short intervals of time. In both the operation could only be regarded as partially successful; both seemed to me to suffer almost as much without stones in their bladders as they did with. I cut and drained both, and the patients are now, I believe, and have been since the operation, perfectly well. Though lithotrity was successful in each, lithotomy was more so. I cannot, under the circumstances referred to in the last two groups of cases, admit that I could have obtained equally satisfactory results by an opening made into the bladder above the pubes.

Permit me to say, in conclusion, that we have, I think, sufficient evidence to show that the last few years have not been uneventful in the history of perineal lithotomy. We have learnt to define pretty accurately what cases are best met by crushing and what by cutting. We have improved our means of arresting any hæmorrhage that may follow the latter proceeding. Means have been methodically and successfully introduced for dealing with some states of the large prostate when it complicates stone. We have recognised the importance of bladder drainage as a necessary part of the after-treatment of some cases of lithotomy, and suitable appliances have been introduced and accepted for this purpose; and, further, the essential details of Listerism have been applied to these operations. Instead of aiming to change our ground and to substitute an abdominal for a perineal section, save under exceptional circumstances, I think we shall find it more advantageous if we endeavour to add further improvements in the directions I have ventured to indicate, in the perfecting of an operation which, of all others, so entirely depends on the precision and dexterity with which it is executed.

I remain, Sir, yours obediently,

Liverpool, April 2nd, 1886. REGINALD HARRISON.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Jan. 30th, 1886, there is reference made to a case of attempted supra-pubic lithotomy by M. Polaillon, which was abandoned on account of anomalous distribution of the peritoneum. It is difficult to understand why a supra-pubic operation was attempted to remove a "stone measuring in circumference four centimetres by two"; stranger yet that it should have been abandoned through dread of wounding the peritoneum; as this may occur without disaster, the following case of epi-cystotomy will illustrate.

John M——, a native of Ireland, aged seventy-three, was admitted to the Buffalo Hospital of the Sisters of Charity on Sept. 22nd, 1884, with a history of symptoms of stone for the past two years. During the three months prior to admission to the hospital he had suffered intense pain, with cystitis. Examination with the sound revealed the presence of stone in the bladder, greatly enlarged prostate, and subacute cystitis.

On Sept. 23rd, 1884, in the presence of a large number of medical gentlemen, and with the assistance of my colleagues, Professors Cronyn and Stockton and Drs. Mickle and Clark, I performed epi-cystotomy. An effort was made to use Petersen's method of throwing the bladder upwards and forwards by introducing a rubber bag into the rectum and inflating it; but owing to an imperfect apparatus and the excessively enlarged prostate, the attempt was abandoned. The bladder was then injected with about six ounces of a solution of boro-glyceride (all it would hold). The patient took the anæsthetic (ether) badly. There was a constant convulsive movement of the abdominal muscles, and it seemed impossible to produce relaxation. This greatly complicated the operation, and partly accounts for the accident which occurred. The bladder was exposed by the usual incision, and seized by a pair of tissue forceps, which, by the way, are inferior for their purpose to the tenaculum. It was then incised, and a mulberry calculus, $1\frac{3}{8}$ in. in long diameter by 1 in. transversely, extracted with the thumb and forefinger. After washing the bladder out with mercuric bichloride solution (1 in 1000), a short rubber drainage-tube was inserted at the lower angle of the wound. The abdominal incision was then closed by silver-wire sutures, with the exception of about half an inch left open for drainage.

About fifteen minutes after the patient had been removed to his bed I was summoned in haste, and found, on reaching him, that he had vomited while recovering from the ether, and that a coil of small intestine about the size of the fist protruded from the wound. The stitches were rapidly cut, the intestine completely returned, and by means of a perineum needle four silver wire sutures were carried through the abdominal walls and the anterior wall of the bladder; then, anchoring the bladder to the abdominal wall, a soft rubber catheter was placed in the bladder per urethram, and a pad of gauze containing wood flour mixed with mercuric bichloride and naphthalin was applied over the wound.

Sept. 25th (8 P.M.): Temperature 101°; some pain in abdomen. Ordered one grain of powdered opium and two grains of camphor powder every four hours.—26th: Slept fairly; temperature 100°; bloody urine flowing freely through the catheter.—27th: Temperature normal; patient feeling well; urine clearer.—28th: Temperature normal; slept well; slight escape of very ammoniacal urine through wound; bladder washed out with boro-glyceride solution.—30th: Bowels fairly moved in response to a cathartic.—Oct. 1st.: Temperature normal; bladder washed out with mercuric bichloride solution (1 in 1000). From this time the patient steadily improved, the urine becoming clearer, and the wound healing completely. He was discharged cured on Oct. 23rd, 1884. Three weeks later he reported himself to Dr. Mickle at the Emergency Hospital, and stated that he was "quite well, and had no further difficulty with his urinary organs."

Notwithstanding the peritoneum was wounded during the operation, the patient made an excellent recovery, without peritonitis or any other untoward symptom. From his advanced age and the complications above mentioned, this case was fairly a crucial test of the operation of epi-cystotomy, and goes far in support of the claim I have made for it in a previous paper. I suggest that an effective method in dealing with such an exceptional case as reported by M. Polaillon would be to pass through the abdominal wall and the anterior wall of the bladder a long steel pin, thus fastening the peritoneal surface of the bladder to that of the abdominal parietes, and, either before or after incising the peritoneum, to stitch with fine catgut sutures the vesical layer of peritoneum to that lining the abdominal walls, in this manner preventing the escape of urine into the peritoneal cavity. The fact that the bladder in M. Polaillon's case was diseased would suggest the propriety of inserting a tube into the bladder at the lower portion of the wound for thorough drainage. The impunity with which exploratory incisions are now made in cases of abdominal tumours lends strength to this method.

The advantages of the supra-pubic operation I had the honour to point out in a paper read before the American Surgical Association at its meeting in Washington, D.C., held April 30th to May 3rd, 1884, in which I made use of the following language: "As regards the relative merits of epi-cystotomy and litholapaxy, recently discussed by Dittel, in properly selected cases and in experienced and skilful hands, the former will probably maintain its present position, but my own opinion is that supra-pubic cystotomy will prove by far the safer operation in the hands of the average surgeon." A more extensive experience in this class of cases has but served to confirm me in this position. It is gratifying to find my views endorsed by so eminent an authority as Sir Henry Thompson in THE LANCET for July 25th, 1885, more than a year afterwards, where he says: "The problem, then, left for solution is what is the best cutting operation for hard calculi (urates and oxalates) which weigh from about two ounces and up-

[3] Med.-Chir. Trans., vol. lxv. [4] THE LANCET, Jan. 16th, 1886.

Digitized by Google

wards, as well as for those not quite so large, which are so peculiar in form (as occasionally, but very rarely, happens) that the lithotrite fails to grasp or retain them? I think there is no doubt about the answer—viz., that it is the suprapubic and not the lateral position." And again: "Finally, I think I am quite justified in believing that unless the operator has had a large experience of lithotrity (and there are not many of whom this can be affirmed), the high operation would generally be a safer proceeding than crushing for a calculus which is hard and much above an ounce in weight." In regard to the danger of impotence from peritoneal section, to which I alluded in my paper above mentioned, I am permitted to quote the following extract from a private letter received from my friend, Dr. A. H. Haemstadt of Pottsville, Pa.—a lithotomist of large experience: "Your eleventh accident—impotence—is well put; only one of eighteen whom I cut as boys, grown to manhood and married, has had issue as far as I can learn."

One of the strongest arguments in favour of the suprapubic operation is that it avoids all interference with the *genital* organs, thus preventing the so frequent reflex disturbance of the nervous system accompanying the introduction of instruments through the urethra—a practical point to which, I believe, I was the first to publicly invite attention. I am, Sir, yours truly,

W. G. TREMAINE, M.D.,
Major and Surgeon, U.S. Army; Surgeon-in-Chief, Buffalo Sisters' Hospital, &c.

Buffalo, N.Y., Feb. 15th, 1886.

PASTEUR'S EXPERIMENT.

To the Editor of THE LANCET.

SIR,—In your leader of March 20th, and in the special article in THE LANCET of last week, which are devoted to a description of the method by which M. Pasteur secures and uses the protective virus, the attention of the medical profession is intelligently drawn to a subject of great interest and importance. For the moment M. Pasteur is concerned with hydrophobia alone, but the issues presented to the mind of anyone who has become practically acquainted with the inception and progression of disease are many and far-reaching. It may be said of all disease that the period of active pathological change is preceded by a period of passive fermentation, which prepares the whole animal structure for the consequent and more perceptible morbid process. At present, however, this period of latency in the majority of diseases cannot be exactly determined, and, indeed, the conditions and circumstances of disease, regarded as they are at present under the somewhat uncertain light of our knowledge, are strangely various and bewildering. Perhaps, if the jaded general practitioner of medicine, careful and troubled like Martha about many things, were to express his mind freely concerning the mysterious vagaries of his many-faced adversary, Virgil's unkind description of the gentler sex—

"Varium et mutabile semper femina"—

would, with a trifling alteration, suit his purpose best. There are, however, certain diseases in which the period of incubation can be exactly determined, and in other cases by careful and long-continued observation the scientific physician has arrived at conclusions which are found to be erroneous only in exceptional cases. M. Pasteur proposes to deal with a disease during its incubation period, and has selected a disease which is "only conveyed by direct contagion, so that the date of the introduction of the poison into the system can be fixed with precision." (THE LANCET, March 20th). At present M. Pasteur proposes merely to inoculate persons who have been bitten by mad dogs, but, as you say in the leader from which I have already made a quotation, "in process of time it may become the fashion to inoculate with the mitigated virus in order to give protection against the possible bites of mad dogs, but at present there seems little likelihood of this practice being established, nor, on the whole, is it desirable." The practice would not, in my opinion, be desirable, because hydrophobia is a disease of the lower animals, and is only occasionally transferred from them to man; but if M. Pasteur succeed in his experiment, it might become desirable that all dogs should be protected by inoculation. By his brilliant discovery Jenner drove out from the midst of the people a terrible and deeply-rooted disease. In like manner M. Pasteur may succeed in removing from the animal world the disease against which his scientific labours have been for some time directed. If success should attend his efforts—and at present there is little reason for anticipating failure—a great advance will have been made in the preventive treatment of disease. I may be too sanguine in expressing my belief that the experiment which is proceeding at Paris is a swift approach towards the clear noonday of scientific medicine of which Jenner's discovery is the brilliant dawn. There is certainly ample reason to be found for the belief in the success which has attended the theory of vaccination in practice, and in the patient and questioning industry of the great French pathologist and chemist. He is indeed a worthy successor of his countryman, Lavoisier, who, dragged down with many others into the ruthless whirlpool of the first Revolution, asked for a fortnight more of life in which to finish an experiment.

In speaking of M. Pasteur and his experiment, one is led naturally enough to consider the manner in which it has been received by those who are opposed to science on purely sentimental grounds, and by those who, with varying degrees of responsibility, take part in the government of the country. In a recent and very admirable work Sir Henry Sumner Maine arrives at the somewhat sad conclusion that science will suffer under a government by the people. I have mentioned Lavoisier and his pathetic request, but, as Carlyle says, "the Republic had no use for experiments," and so the fortnight more of life was denied to the chemist. We have not yet descended to the depth of moral and social dissolution to which the French people were dragged by Robespierre, Marat, and company, but we are hurrying on at a startling pace, and only the other day, at the call of a shrill and shallow sentiment which would send all science to the winds, the Contagious Diseases Acts were removed from the Statute Book. "The day of checks and counterpoises is over," exclaimed Mr. Labouchere some time ago in the *Fortnightly Review*, and the present House of Commons is showing that there is some truth in the exclamation. "Government by the people for the people" (this is the formula I think) will mean a paralysis of scientific effort. True science can never be popular in the ordinary acceptation of the word. Unlike Radicalism, it does not promise well on the surface, and does not leap from a chaos of improbable and indefinite premisses to time-serving and popular conclusions. The best and most useful part of scientific work is hidden from the notice of the multitude. The days of earnest endeavour towards the practical attainment of a great scientific end are unheard of by the busy throng who thrive unthinkingly upon the discoveries that the votaries of science have made. At present we may congratulate ourselves that we are yet some distance from a government by the people, and rejoice in the fact that in spite of the absorbing Irish problem, a Governmental commission is to be appointed to investigate into the subject upon which M. Pasteur is experimenting. The names which you mention are of themselves sufficient to satisfy those interested that the work will be done in a thoroughly efficient fashion. Scientific investigation of the severest kind must always be applied to every discovery of moment, and in the instance of M. Pasteur's experiment the discovery is of the first importance. For my part, I believe that investigation will but prove the truth of the theory by making sure its practical success.

I am, Sir, yours truly,

Glasgow, March 30th, 1886. ROBERT MACPHERSON.

HEALTH-RESORTS FOR PHTHISICAL PATIENTS.

To the Editor of THE LANCET.

SIR,—I read with much pleasure in your issue of March 13th a leading article on Health-resorts for Phthisis. My purpose in writing now is to endorse, with what weight an experience of twenty-two years' practice in Sydney may carry, the truth of your remarks, in so far as they relate to Australia. I have frequently expressed to my medical friends here, and in words almost identical with your own, the great importance of warning consumptive patients, when contemplating removal to New South Wales, against taking up their residence in Sydney or any other place upon the eastern seaboard. During nine months of the year the atmosphere is warm and moist, and the surroundings highly detrimental to the phthisical invalid. Tubercular deposit rapidly undergoes softening, and night sweats, loss

Digitized by Google

of flesh and appetite, with sometimes diarrhœa, ensue. How different, as a rule, the progress of the patient who has been wisely advised to betake himself to the great inland plains, where the air is dry and warm. Living in a town, or, far better, on a sheep or cattle station so situated, he gains flesh, his appetite returns, night sweats cease, and life becomes enjoyable. My case-books afford abundant evidence of cures so brought about. Even when cure has not been effected life has been greatly prolonged. To a young and, as is so often found in the phthisical, a highly intelligent mind continuous absence from the metropolitan centres of southern civilisation is often a sore trial and has a depressing effect. Fortunately my experience enables me to say that an exception to the rule of unbroken residence on the inland plains may be made during the winter quarter. At this season the climate in Sydney is dry and bracing, the very opposite condition to that which exists during the other nine months. I have been in the habit, therefore, of permitting my consumptive patients to visit Sydney during the winter, and when the privilege has not been abused the change of scene and distraction from their own sensations have proved advantageous to them. With this exception, however, it cannot be too strongly urged that phthisical patients should reside permanently upon the inland plains, which are at an elevation of from two to three thousand feet above the sea level.

I am, Sir, yours faithfully,

Sydenham-hill, March 30th, 1886. P. SYDNEY JONES.

UNUSUALLY PROLONGED PERIOD OF INCUBATION OF SMALL-POX.

To the Editor of THE LANCET.

SIR,—The following case of exceptionally long incubation of small-pox appears worthy to be put on record. The proof that the patient was but once exposed to infection, and that only for two hours and a half, is about as strong as available proof on such a matter is likely to be, inasmuch as, until the occurrence of the case in question, there has been no small-pox in Newcastle for above half a year, the last case before this having been notified in July, 1885; neither has the patient been anywhere outside of Newcastle, or in known communication with any infected person except one, or with any other person coming from an infected place. The circumstances are:—

Mrs. A. B—— first began to feel unwell on Friday, the 26th of March. A very sparse eruption of small-pox papules appeared on the 29th (fourth day of illness). On March 6th the patient's brother, T. S——, was discharged from a small-pox hospital upwards of thirty miles distant from here, and came to Newcastle to the house of his sister on the same day. He remained with her for two hours and a half, when he went away by the north train, leaving behind him none of his clothing or other belongings. No communication between the two has taken place since. There is therefore, good reason to believe that in this case the period of incubation extended from the 6th to the 26th of March inclusive, or in all twenty-one days. The patient bears faint vaccination cicatrices from infancy, equal in area to about six ordinary vaccine vesicles. It would be interesting to know how far the incubative stage has been affected by these.—I am, Sir, yours obediently,

HENRY E. ARMSTRONG,
Medical Officer of Health, Medical Supt., Newcastle Small-pox Hospital, &c.

Newcastle-on-Tyne, April 6th, 1886.

BIRMINGHAM.

(From our own Correspondent.)

THE MEDICAL INSTITUTE.

THE annual meeting of the Medical Institute was held on the 25th ult., under the presidency of Mr. J. S. Gamgee. A portrait of the late Dr. Russell was presented by Mrs. Russell, and accepted with much satisfaction as a memento of the esteem with which the high personal character and professional attainments of Dr. Russell are remembered by the members of the institute. The report shows that the library is increasing in popularity and usefulness, the circulation of books being more than 400 as compared with the numbers of the previous year. The financial position has improved somewhat, but still shows a deficit between the annual income and expenditure of a little less than £50. To meet this and a bank overdraft of £108 the Committee show good security, but feel that the prospects of the institute would be more encouraging if there was an absolute freedom from debt.

HEALTH LECTURES.

The third series of lectures have been well attended and well delivered. The interest manifested in these discourses has been well sustained and their success assured by the reputation and ability of the lecturer. The subjects have been such as to set an intelligent public thinking for themselves on the many problems associated with the more common ailments which affect the health and constitute the enjoyment or otherwise of daily life. After such teaching no reasonable excuse can be afforded for preferring the ignorance of bliss which is frequent among those who "enjoy" bad health.

THE JAFFRAY SUBURBAN HOSPITAL.

The 15th of March was a memorable day in the history of this young and promising branch, for it witnessed the transfer of the first detachment of patients from the parent institution. They were conveyed from the general hospital in ambulances and carriages, and on their arrival were at once placed in comfortable quarters in the pure atmosphere of their temporary home. Surrounded by plants, flowers, pleasing pictures, and readable books, the bracing air and cheerful adjuncts ought to produce palpable effects upon the chronic sufferers, and materally aid in restoring them to health and vigour. The value of this auxiliary to the older hospital will be immense, as it cannot fail to add to the prestige which the latter institution has accumulated during a period of more than a century in the cause of humanity.

THE WORKHOUSE INQUIRY.

As a result of the recent inquiry by the Local Government Board concerning the difference between the guardians andtheir senior medical officer, I regret to say that the authority has called for the resignation of the medical officer. It is difficult for outsiders to appreciate the merits of a dispute upon matters of discipline in technical details. The senior medical officer has held his position for a number of years, and has worked with zeal; that this has not been tempered with discretion is the opinion of the higher powers, and, like many good officials, he must yield with as good a grace as possible to the force of circumstances which he cannot control.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

GATESHEAD DISPENSARY.

AT the annual meeting of the Gateshead Dispensary held recently, the resignation of Dr. Wm. Robinson was received and accepted with regret. Dr. Robinson, who has been appointed medical officer of health for the borough, has acted on the honorary staff of the dispensary for nearly thirty years. The Committee passed a hearty vote of thanks for his long and valuable services. It was mentioned in the report presented by Dr. Hardy at the same meeting, that the work of the year had compared favourably with that done in previous years. The number of patients under treatment at the date of the last report was 221. This, with 2912 admitted during the year, makes the total number of letter-patients treated 3133, as compared with 2815 in the previous year. The letter patients consist of 2620 home-patients and 513 out-patients. The number of casuals was 9841, this being made up of 290 accidents, teeth extractions, and 8898 medical cases. The casualty patients of the year before were 10,003, and notwithstanding that the twopenny system has been carried out during the whole year the number has been practically maintained. During two or three months of the year a severe epidemic of measles was experienced; this was also followed by a slight one of scarlet fever, but the dispensary patients had been entirely free from the more severe forms of zymotic disease. The Samaritan fund had been of great service, and was largely drawn upon. It may be mentioned that the charge of twopence for the casualty patients had yielde[d]

Digitized by Google

over £74 to the funds of the dispensary without in any way diminishing the attendance of patients.

HARTLEPOOL.

At the late meeting of the Hartlepool Port Sanitary Authority it was stated that the plan for the new hospital had been conditionally approved by the Local Government Board. The Rev. H. E. Savage offered to provide trained nurses, beds, &c., for temporary cases of small-pox if the authority would furnish a suitable building. A committee was appointed to frame bye-laws to regulate the removal of cases occurring on shipboard to the hospital. The medical officer, Dr. Biggart, reported that there were now in the tents seven cases of small-pox and five of fever, also that the former disease was on the increase. There had been fourteen cases from Hartlepool during the month, and eight from West Hartlepool.

Newcastle-on-Tyne, March 24th.

PARIS.

(From our own Correspondent.)

THE LATE PROFESSOR CHARLES ROBIN.

IN the will of the late Professor Charles Robin, which has lately been published, I find the following paragraph. After giving instructions about his funeral, which he particularly desired should be civil, he says: "If I die at Paris, my autopsy should be performed, as soon as possible after death, by one of the prosectors or assistants of the Faculty, designated by the the dean. My brain and my eyes should be removed, to be studied comparatively, the right eye with the left, which was wounded in 1835 by a blow with a stick, in order that the origins and optic convolutions may be properly studied." On this extract, Dr. Fano, a well-known ophthalmologist, makes the following remarks in his "Journal d'Oculistique":—"Charles Robin having died in the last quarter of 1885, it would be fifty years since his left eye was wounded. During all that time the right eye was never in any way affected, and everyone knows the fatigue that this organ must have been subjected to in a *savant* who spent a great portion of his days in working with the microscope, as he was a professor of histology. What becomes of the theory of what is termed sympathetic ophthalmia in presence of such a fact? What should be thought of the doctrine professed by some ophthalmologists relating to the necessity of enucleating a wounded eye to prevent sympathetic ophthalmia of a healthy eye?"

M. PASTEUR.

M. Pasteur is being loaded with honours, as he has been decorated by nearly all the Sovereigns of Europe, for his remarkable discovery of the means of prevention of hydrophobia, and the King of Portugal has just sent him an autograph letter, conferring on him the Grand Cordon of the Order of St. Jacques, a decoration specially designed to recompense scientific merit. This letter was handed to M. Pasteur by Dr. Bournay, one of the doctors who arrived in Paris on the 2nd inst. with three children from Portugal, reported to have been bitten by a mad dog. The children are sent at the expense of the Queen, to undergo M. Pasteur's treatment. They were accompanied by relatives, and by Drs. d'Abreu and Bournay, the former of whom will remain in Paris to study at his own expense M. Pasteur's system of inoculations. The French Minister of the Interior sent to M. Pasteur's laboratory about three days ago two foreigners who had been sent from Rome—a police agent and a gaoler,—reported to have been bitten by mad dogs. Eight more Russians arrived on Sunday morning, accompanied by a doctor and a veterinary surgeon, who took them direct to M. Pasteur's laboratory. They were reported to have been bitten, some by a mad wolf and the others by mad dogs. They were all wounded in the face; and as they are in good health, M. Pasteur inoculated them at once. Another patient of the first Russian party of nineteen, already referred to, died at the Hôtel Dieu on Friday last with symptoms of hydrophobia. He was one of the patients who was so frightfully mutilated in the face, and one of the teeth of the rabid wolf was found broken in his jaw at the necropsy. I may here remark that the first patient who died became affected with rabies twenty days after having been bitten, and the one now under notice thirty-two days. The treatment was commenced a fortnight after they were bitten. The treatment of the other seventeen having terminated without any untoward circumstance, they were about to return to their native country, when, on second consideration, they have been detained in order to undergo another course of M. Pasteur's treatment. After a long debate at the Academy of Medicine at Rome, it was decided to send one of its members to Paris, at the expense of the Municipality, to study and follow M. Pasteur's anti-rabic treatment. It is reported that the German Government have also decided upon sending a mission to Paris to examine and report upon M. Pasteur's method. It is presumed that this mission will be confided to M. Virchow and M. Koch. In anticipation of some more convenient place being provided for M. Pasteur to carry out his method, the Municipal Council have placed at his disposal some wooden huts that had been erected for another purpose in the Rue Vauquelin, and which are now unoccupied. The *Official Journal* has just published the eighth and ninth lists of the subscription for the Pasteur Institute, which amounts to 495,462 francs.

Paris, April 6th.

MEDICAL NOTES IN PARLIAMENT.

Workhouse Dietary Tables.

IN the House of Lords, on the 2nd inst., Lord Sudeley, in reply to a question put by Viscount Barrington touching the death of an infant in Totnes Workhouse from overfeeding, stated that the General Consolidated Order issued by the Poor-law Commissioners provides that paupers shall be dieted with the food set forth in the dietary table prescribed for the use of the workhouse. The dietary table at Totnes directs that children under two years of age shall be dieted at discretion. The order also provides that the medical officer shall be consulted by the matron as to the nature of the food of the infants, and makes it his duty to give all necessary instructions as to the diet or treatment of children. The Local Government Board would cause further inquiries to be made at Totnes into this special case.

Lunacy Acts Amendment Bill.

On the 6th inst., on the report of amendments in the Lunacy Acts Amendment Bill, certain amendments were proposed by the Lord Chancellor, and after a conversation, in which Lord Halsbury and the Earl of Selborne took part, was agreed to. None of them affected the principle of the Bill, and some of them were merely verbal. Lord Milltown and Lord Hobhouse proposed amendments relating to private asylums, which were rejected, and the report was afterwards received.

The Idiots Bill.

This Bill passed through committee without amendment.

Contagious Diseases Acts Repeal (No. 2) Bill.

On the 2nd inst. the House of Commons went into Committee on this Bill, when Mr. Campbell-Bannerman stated that it was the intention of the Government to continue this year the contributions which had been made under the authority of the Acts to certain hospitals. The Bill then passed through Committee, and, having been reported without amendment to the House, was read a third time.

Medical Act (1858) Amendment Bill.

On the 5th inst., on the motion of Sir L. Playfair, leave was given to introduce a Bill to amend the Medical Act, 1858. The Bill was brought in and read a first time.

The Case of William Goslin.

On the 7th inst., in reply to Mr. W. James, Mr. Childers stated that, so far as he had been able to ascertain, the prisoner William Goslin complained to the medical officer on Monday, the 15th ult. The next day he was taken off the treadwheel. On the 17th he was ordered medicine and put to bed in his cell. On the 19th he was ordered into hospital, and he died on the 21st. The medical officer did not seem to have recognised sufficiently early that the case was one of pneumonia. He should order a most strict inquiry into the whole matter.

THE quinquennial census of the French population is to be taken on the 30th prox.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT a quarterly meeting of the Council held on Thursday, April 8th, Mr. Bruce Clarke was awarded the Jacksonian Prize for 1885, the subject being "The Diagnosis and Treatment of such Affections of the Kidney as are amenable to direct Surgical Interference." The subject for the Prize for the present year is "The Pathology, Diagnosis, and Surgical Treatment of Diseases of the Thyroid Gland." It was resolved that the subject for 1887 be "On the Pathology, Diagnosis, and Treatment of Tumours of the Bladder." No dissertation was received for the Collegial Triennial Prize. It was resolved that the following be the subject of the next Collegial Triennial Prize—viz.: "On the Structure and Functions of the Ganglionic System of Nerves in Man, to be illustrated by reference to Comparative Anatomy."

Mr. Marshall brought forward the following motion, which was seconded by Sir J. Paget, and carried by a large majority:—

"That the Council have considered the resolution carried at the meeting of Fellows and Members held on Dec. 17th last, in reply to a communication from the Council bearing date the 16th of the previous month, which resolution is as follows:—'That the answer of the Council is not satisfactory, and that the Council be respectfully requested to reconsider the subjects: (1) Of the representation of Members of the College; and (2) of submitting for approval any alterations proposed to be made in the constitution or the relations of the College, or in any of its bye-laws, to a meeting of the Fellows and Members.' That the Council, in reply to this resolution, have to make the following statement:—

"1. As regards the subject of the 'representation of the Members of the College.' Whilst fully recognising the gravity of the question of the representation of Members of the College (presumably in or upon the Council), the desire of Members to be so represented, and the advantage of uniting in harmonious relationship all the constituent elements of the College, the Council still retain the opinion already expressed by them, 'that it is not desirable to diminish the privileges of the Fellowship by depriving Fellows of the exclusive rights of electing to the Council and of being eligible to become members thereof.' Entertaining this view, the Council are unwilling, and, indeed, unable consistently, to take proceedings for making any organic change in the constitution of the College which would impair the present status of the Fellows, by whom alone they have been elected to office as the governing body of the College. The two methods of widening the basis of the Fellowship, one by election and the other by examination, just agreed to by the Council, by means of which it is hoped that the acquisition of the Fellowship and its concomitant rights by Members of the College will be facilitated, involve no organic or constitutional change in the government of the College. The Council are quite aware, however, that these new proposals do not constitute a complete response to the desire of Members to a share of representation in or upon the Council. At the same time they would point out that no detailed plan, formulated by the two bodies mutually interested in the question—that is, the Fellows and the Members—by means of which a share of representation might be assigned to the latter, has yet been presented to the Council. The Council are quite prepared to give careful attention to any such jointly authorised plan approved by a majority of each body, and would found their decisions concerning it, not merely upon a consideration of the relative interests of the Fellows and Members, but also upon a due regard to the position and future welfare of the College. 2. That in reference to the other subject—viz., that of submitting questions to general meetings of Fellows and Members,—the Council have to reply that, whilst they still adhere to the opinion that it is unnecessary, and would as a rule be impracticable, to refer certain questions to the consideration of a general meeting of the Fellows and Members, they wish to state that, in accordance with their declared view, 'they would be glad to consult the Fellows and Members when larger questions arise, such as those which concern the constitution of the College,' and they would take care to report the conclusions at which they might arrive, in regard to any plan presented to them concerning the representation of Members, to a special meeting of Fellows and Members. The Council, however, could only regard such a meeting as consultative, and not as possessed of a direct power to veto or alter their decisions."

It was moved by Mr. Lund, and seconded by Mr. Macnamara: "That the Council do hereby rescind so much of the resolution passed at the meeting of the Council of the 12th of November, 1885, as relates to the non-desirability of Members participating in the election of Fellows as members of Council, and do substitute in the first paragraph of the said resolution the following words—viz.: 'That it is not desirable to diminish the privileges of the Fellowship by depriving Fellows of the exclusive right of being eligible to become members of the Council.'"

This motion was lost by 17 to 4.

Mr. Henry Cayley of Calcutta and Mr. George Yeoman Heath were elected Fellows of the College under Sec. 5 of the Charter relating to Members of fifteen years' standing.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examination in Anatomy and Physiology at a meeting of the Board of Examiners on the 3rd inst., and when eligible will be admitted to the Pass Examination:—

J. L. Owen, Hugh Robert, G. H. Wilson, F. W. Vernon, G. A. O'Brien Reid, and W. P. Johnstone, Edinburgh University; R. C. Wakefield, Glasgow; J. J. Hanley, Dublin; W. W. Margemont, Ceylon Medical College; H. M. Holt, Yorkshire College, Leeds; H. B. Williams and F. Cant, Owens College, Manchester; G. A. Waring, Belfast; G. H. Douthwaite, Birmingham.

Passed in Anatomy only:—

Algernon J. Horton, Birmingham; A. H. Barstow, W. H. Thompson, and J. S. Vassalli, Yorkshire College, Leeds.

Passed in Physiology only:—

R. B. Morris, E. A. Humphreys, Thomas Boulton, and R. H. Read, Owens College, Manchester; J. T. Harty, Cork; G. J. Wontersz, Ceylon and Edinburgh University; G. F. Barber, Sheffield Medical School; W. H. Webster, Edinburgh; R. T. Wrightman, Sheffield Medical School.

Candidates referred for six months, 6; for three months, 15.

Passed on the 6th inst.:—

W. Twyford, J. E. Platt, H. Ramsden, S. F. Mawson, A. H. Marsh, W. Nuttall, A. E. Brindley, H. Langdale, T. A. Goodfellow, and H. C. Faulke, Owens College, Manchester; W. S. Lang, Edinburgh University; G. D. Freer, Birmingham; R. G. Sheldon, Liverpool; A. D. Tripp, Guy's Hospital; Frederick Barker, St. Thomas's Hospital; H. C. Fox and J. P. Smith, Middlesex Hospital; J. L. Firth, King's and University Colleges; O. M. Jones, London Hospital.

Passed in Anatomy only:—

C. Ridley Pigg and T. F. Clemson, Owens College, Manchester.

Passed in Physiology only:—

H. Vermaak and G. Saint Johnston, Birmingham; J. Robinson, Yorkshire College, Leeds; W. Hague, Owens College, Manchester; W. Jenner Best, London Hospital.

Candidates referred for six months, 7; for three months, 9.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 1st inst.:—

Hodge, William Theodore, M.R.C.S., Middleton, Tamworth.
Hubbard, Daniel Lovett, The Grove, Clapham-road.
Nevins, John Ernest, Abercromble-square, Liverpool.
Rake, Herbert Vaughan, Fordingbridge, Salisbury.
Wheatley, James, Edgerton, Huddersfield.

AT the monthly meeting of the Association of Public Sanitary Inspectors on the 5th inst. Dr. Alfred Carpenter delivered a lecture on Sanitary Legislation.

ON the 4th inst. a church parade of the various temperance orders having lodges in South London was held on behalf of the London Temperance Hospital.

MURCHISON SCHOLARSHIP EXAMINATION.—We are asked to state that application for admission to this examination will be received up to the 11th inst., as originally advertised.

AT a conference on sanitation, on the 6th inst., in connexion with the Architectural and Building Trades' Exhibition now being held at the Agricultural Hall, Mr. R. K. Burton read a paper on Drain Testing, and Mr. Howard Smith delivered an address on Sanitation. A discussion followed.

Digitized by Google

THE RIVER LIFFEY.—At a meeting of the Dublin Corporation this week a sum of £200 was voted for cleansing the foreshore of the river Liffey.

ON the 1st inst., Dr. Louis Parkes delivered a lecture at the Parkes Museum on London Vestries and the Administration of Sanitary Law in the Metropolis. The address was followed by a discussion, in which Mr. Shirley Murphy, Mr. Mark Judge, and others took part.
